20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

This report is a collection, correlation, codification, and recording of best knowledge, opinion, and judgment in the area of aerodynamic stability and control prediction methods. It presents substantiated techniques for use (1) early in the design or concept study phase, (2) to evaluate changes resulting from proposed engineering fixes, and (3) as a training on cross-training aid. It bridges the gap between theory and practice by including a combination of pertinent discussion and proven practical methods. For any

20.
Abstract (continued)

given configuration and flight condition, a complete set of stability and control derivatives can be determined without resort to outside information. A spectrum of methods is presented, ranging from very simple and easily applied techniques to quite accurate and thorough procedures. Comparatively simple methods are presented in complete form, while the more complex methods are often handled by reference to separate treatments. Tables which compare calculated results with test data provide indications of method accuracy. Extensive references to related material are also included.

FOREWORD

The current volume entitled "USAF Stability and Control Datcom" has been prepared by the Douglas Aircraft Division of the McDonnell Douglas Corporation under Contracts AF33(616)-6460, AF33(615)-1605, F33615-67-C-1156, F33615-68-C-1260, F33615-70-C-1087, F33615-71-C-1298, F33615-72-C-1348, F33615-73-C-3057, F33615-74-C-3021, F33615-75-C-3067, and F33615-76-C-3061. (The term Datcom is a shorthand notation for data compendium.) This effort is sponsored by the Control Criteria Branch of the Flight Control Division, Air Force Flight Dynamics Laboratory, Wright-Patterson Air Force Base, Dayton, Ohio. The Air Force project engineers for this project were J. W. Carlson and D. E. Hoak. The present volume has been published in order to replace the original work and to provide timely stability and flight control data and methods for the design of manned aircraft, missiles, and space vehicles. It is anticipated that this volume will be continuously revised and expanded to maintain its currency and utility. Comments concerning this effort are invited; these should be addressed to the procuring agency.

SECTION 1

GUIDE TO DATCOM

Fundamentally, the purpose of the Datcom (Data Compendium) is to provide a systematic summary of methods for estimating basic stability and control derivatives. The Datcom is organized in such a way that it is self-sufficient. For any given flight condition and configuration the complete set of derivatives can be determined without resort to outside information. The book is intended to be used for preliminary design purposes before the acquisition of test data. The use of reliable test data in lieu of the Datcom is always recommended. However, there are many cases where the Datcom can be used to advantage in conjunction with test data. For instance, if the lift-curve slope of a wing-body combination is desired, the Datcom recommends that the lift-curve slopes of the isolated wing and body, respectively, be estimated by methods presented and that appropriate wing-body interference factors (also presented) be applied. If wing-alone test data are available, it is obvious that these test data should be substituted in place of the estimated wing-alone characteristics in determining the lift-curve slope of the combination. Also, if test data are available on a configuration similar to a given configuration, the characteristics of the similar configuration can be corrected to those for the given configuration by judiciously using the Datcom material.

The various sections of the Datcom have been numbered with a decimal system, which provides the maximum degree of flexibility. A "section" as referred to in the Datcom contains information on a single specific item, e.g., wing lift-curve slope. Sections can, in general, be deleted, added, or revised with a minimum disturbance to the remainder of the volume. The numbering system used throughout the Datcom follows the scheme outlined below:

Section: An orderly decimal system is used, consisting of numbers having no more than four digits (see Table of Contents). All sections are listed in the Table of Contents although some consist merely of titles. All sections begin at the top of a right-hand page.

Page: The page number consists of the section number followed by a dash number. Example: Page 4.1.3.2-4 is the 4th page of Section 4.1.3.2.

Figures: Figure numbers are the same as the page number. This is a convenient system for referencing purposes. For pages with more than one figure, a lower case letter follows the figure number. Example: Figure 4.1.3.2-50b is the second figure on Page 4.1.3.2-50. Where a related series of figures appears on more than one page, the figure number is the same as the first page on which the series begins. Example: Figure 4.1.3.2-56d may be found on Page 4.1.3.2-57 and is the 4th in a series of charts. Figures are frequently referred to as "charts" in the text.

Tables: Table numbers consist of the section number followed by an upper case dashed letter. Example: Table 4.1.3.2-A is the first table to appear in Section 4.1.3.2.

Equations: Equation numbers consist of the section number followed by a lower case dashed letter. Example: 4.1.3.2-b is the second equation (of importance) appearing in Section 4.1.3.2. Repeated equations are numbered the same as for the first appearance of the equation but are called out as follows: (Equation 4.1.3.2-b).

The major classification of sections in the Datcom is according to type of stability and control parameter. This classification is summarized below:

Section 1. Guide to Datcom and Methods Summary (present discussion including the Methods Summary)

Section 2. General information

Section 3. Reserved for future use

Section 4. Characteristics at angle of attack

Section 5. Characteristics in sideslip

Section 6. Characteristics of high-lift and control devices

Section 7. Dynamic derivatives

Section 8. Mass and inertia

Section 9. Characteristics of VTOL-STOL aircraft

The information in Section 2 consists of a complete listing of notation and definitions used in the Datcom, including the sections in which each symbol is used. It should be noted that definitions are also frequently given in each section where they appear. Insofar as possible, NASA notation has been used. Thus the notation from original source material has frequently been modified for purposes of consistency. Also included in Section 2 is general information used repeatedly by the engineer, such as geometric parameters, airfoil notation, wetted-area charts, etc.

Sections 4 and 5 are for configurations with flaps and control surfaces neutral. Flap and control characteristics are given in Section 6 for both symmetric and asymmetric deflections. Section 4 includes effects of engine power and ground plane on the angle-of-attack parameters.

The Datcom presents less information on the dynamic derivatives (Section 7) than on the static derivatives, primarily because of the relative scarcity of data, but partly because of the complexities of the theories. Furthermore, the dynamic derivatives are frequently less important than the static derivatives and need not be determined to as great a degree of accuracy. However, the Datcom does present test data, from over a hundred sources, for a great variety of configurations (Table 7-A).

If more than preliminary-design information on mass and inertia (Section 8) is needed, a weights-and-balance engineer should be consulted.

Section 9 is a unified section covering aerodynamic characteristics of VTOL-STOL aircraft, with the exception of ground-effect machines and helicopters. The Datcom presents less information in this area than that presented for conventional configurations because of the scarcity of data, the complexities of the theories, and the large number of variables involved. In most cases the Datcom methods of this section are based on theory and/or experimental data such that their use is

restricted to first approximations of the aerodynamic characteristics of individual components or simple component combinations. However, the Datcom does present a literature summary from over six hundred sources for a great variety of VTOL-STOL configurations (Table 9-A).

It should be noted that the characteristics predicted by this volume are for rigid airframes only. The effects of aeroelasticity and aerothermoelasticity are considered outside the scope of the Datcom.

The basic approach taken to the estimation of the drag parameters in Section 4 has been found to be satisfactory for preliminary-design stability studies. No attempt is made to provide drag estimation methods suitable for performance estimates.

Each of the major divisions discussed above, notably Sections 4, 5, 6, and 7, is subdivided according to vehicle components. That is, the information is presented as wing, body, wing-body, wing-wing, and wing-body-tail sections. The latter three categories generally utilize component information as presented in the first two categories and add the appropriate aerodynamic interference terms. In some cases, however, estimation methods for combined components as a unit are presented. Each section of the Datcom is organized in a specific manner such that the engineer, once familiar with the system, can easily orient himself in a given section. A typical section is diagramed below:

Section Number and Title

Tables

Working Charts

In general, each section is organized according to speed regimes. However, Sections 6.3.1 and 6.3.2 are restricted to the hypersonic speed regime and Section 9 to the low-speed transition-flight regime. In a few sections, where applicable, material is included for the rarefied-gas regime as paragraph E. The material for each speed regime is further subdivided into an introductory discussion of the fundamentals of the problem at hand, a detailed outline of specific methods, and sample problems illustrating the use of the methods presented. In the selection of specific methods, an attempt has been made to survey all known existing generalized methods. All methods that give reasonably accurate results and yet do not require undue labor or automatic computing equipment have been included (at least this is the ultimate goal). Where feasible, the configurations chosen for the sample problems are actual test configurations, and thus some substantiation of the methods is afforded by comparison with the test results.

To facilitate the engineer's orientation to those Datcom sections that use a build-up of wing, wing-body, and wing-body-tail components, a Methods Summary has been included at the end of this section. In addition, the methods of Sections 6.1 and 6.2 are also included in the Methods Summary. The contents of the Methods Summary present the following: (1) the wing, wing-body, and wing-body-tail equations available in each speed regime, (2) the sections where the equation components are obtained, (3) the limitations associated with the equations and their respective components (limitations from design charts are not included), and (4) identification of the parameters that are based on exposed planform geometry that are not specified by the subscript e.

Sometimes the same limitations, such as "linear-lift range," may occur for more than one component in an equation. To avoid repetition, the same limitation is not repeated for each component. The list of limitations should not be construed as effectively replacing the discussion preceding each Datcom method. It remains essential to read the discussion accompanying each derivative to ensure an effective application of each method.

Proper use of the Methods Summary will enable the engineer to organize and plan his approach to minimize the interruptions and the time needed to locate and calculate the independent parameters used in the equation under consideration.

The Datcom methods provide derivatives in a stability-axis system unless otherwise noted. Transformations of stability derivatives from one axis system to another are developed in many standard mathematics and engineering texts. In FDL-TDR-64-70, several coordinate systems are defined and illustrated, and coordinate transformation relations are given.

All material presented in the Datcom has been referenced; plagiarizing has been specifically avoided. In general, material that has not been referenced has been contributed by the authors.

In many of the sections, substantiation tables are presented that show a comparison of test results with results calculated by the methods recommended. Geometric and test variables are also tabulated for convenience in comparing these results. Wherever possible, the limits of applicability for a given method have been determined and are stated in the text.

The working charts are presented on open grid, which in general constitute an inconvenience to the user. However, with a few exceptions, the grids used are of two sizes only: centimeter and half-inch grid sizes. This enables the engineer to use transparent grid paper to read the charts accurately.

Another set of documents similar in intent to the Datcom is the "Royal Aeronautical Society Data

Sheets," available from the Royal Aeronautical Society of Great Britain. These documents are particularly useful from the standpoint that foreign source material is strongly represented in them; whereas the Datcom emphasizes American information.

As stated in the introduction, the work on the Datcom will be expanded and revised over the years to maintain an up-to-date and useful document. In order to help achieve this goal, comments concerning this work are invited and should be directed to the USAF Procuring Agency so that the effort may be properly oriented.

	1. Plug and flap-type spoilers

2.1 GENERAL NOTATION

A complete summary and definition of all notation used in the Datcom is given in this section. The summary is divided into upper and lower case English, upper and lower case Greek, derivatives, and abbreviations. In all cases a general alphabetical listing is used. Throughout the Datcom units are in pounds, feet, seconds, and degrees unless otherwise specified.

A. ENGLISH SYMBOLS

SYMBOL	DEFINITION	SECTIONS
A	aspect ratio of surface, based on total planform, $\frac{b^2}{S}$	Several
A', A''	aspect ratios of forward and aft surfaces, respectively	4.5.1.1 7.4.1.1 7.4.4.1
$\bar{A}$	transonic aspect-ratio similarity parameter, $A\left(\frac{t}{c}\right)^{1/3}$	4.1.4.2
A_D	duct aspect ratio, $\frac{d_e}{c}$	9.3 9.3.1 9.3.2 9.3.3
A_H	aspect ratio of auxiliary horizontal surface, aft tail or canard, $\frac{b_H^2}{S_H}$	Several
A_{H_e}	aspect ratio of exposed horizontal tail	6.2.1.2
$A_H e_H$	effective aspect ratio of horizontal stabilizer	4.5.3.2
A_I	inlet duct area for jet engine	4.6 4.6.1 4.6.3
A_{U_e}	aspect ratio of exposed lower vertical panel	Several
$(A)_V$	geometric aspect ratio of isolated vertical panel, with span and area of panel measured to body center line	Several
A_{V_e}	aspect ratio of exposed upper vertical panel	Several
$(A)_{V(B)}$	aspect ratio of vertical panel in presence of body	Several

SYMBOL	DEFINITION	SECTIONS
$(A)_{V(HB)}$	vertical-panel aspect ratio in presence of horizontal tail and body	Several
A_W	aspect ratio of wing	Several
A_{bw}	aspect ratio of the basic wing	Several
A_e	aspect ratio of exposed (panels joined together) surface, $\frac{b_e^2}{S_e}$	Several
A'_e, A''_e	aspect ratios of forward and aft exposed surfaces, respectively	4.4.1 4.5.1.1 4.5.1.2 7.4.1.1
A_{eff}	1. effective aspect ratio of surface as determined by tip flow separation	4.4.1 5.3.1.1 5.6.1.1
	2. effective aspect ratio of the vertical panel	Several
A'_{eff}	effective aspect ratio of forward surface as determined by tip flow separation	4.5.1.1
$(A_e)_i$	aspect ratio of exposed inboard panels of wing	4.3.2.2
A_f	aspect ratio of flap or control surface, $\frac{b_f^2}{S_f}$	6.1.6.1 6.1.6.2 6.2.1.1
A_g	aspect ratio of glove of a double-delta or a cranked wing	4.1.3.2 5.1.2.1
A_i	1. aspect ratio of that portion of main surface immersed in propeller slipstream, $\frac{b_i}{c_i}$	4.6 4.6.1
	2. aspect ratio of planform formed by the two inboard panels of wing	Several
A_o	aspect ratio of planform formed by the two outboard panels of wing	4.1.5.1 4.1.5.2
A'_o	aspect ratio of planform formed by the two constructed outboard panels of wing	4.1.4.2 4.3.2.2 5.1.2.1
A_s	aspect ratio of a particular spanwise wing section	6.1.5.1
A_t	1. aspect ratio of wing based on total wing area, including flap extension	6.1.4.1 6.1.4.2
	2. aspect ratio of total wing based on extended wing chord, using the particular section value for the chord	6.1.5.1
A_1, A_2	aspect ratio of constructed panels of non-straight-tapered wings	4.1.3.2
a	1. difference in lift-curve slope, or $(C_{L_\alpha}$ at $M_{fb}) - (C_{L_\alpha}$ at $M_a)$	4.1.3.2
	2. $\frac{\tan \Lambda_{HL}}{\beta}$	6.1.6.1

SYMBOL	DEFINITION	SECTIONS
	3. distance from the quarter-chord point of the MAC of the horizontal tail to the plane of tip vortex cores	4.4.1 4.5.1.1 7.4.4.1
	4. major axis of elliptical-body cross section	4.2.1.2 4.2.2.2 4.2.3.1 4.2.3.2
	5. propeller inflow factor	4.6 4.6.4
	6. forward diameter of a cone frustum	4.2.2.1
	7. linear acceleration	8.1
	8. nose diameter of forebody or base diameter of afterbody	4.2.3.1
	9. speed of sound	6.3.2
a_t	speed of sound at nozzle throat	6.3.2
a_0	blade section lift-curve slope	9.1
$a_1, a_2, a_3, \ldots$	diameter at forward end of given body segment	Several
a.c.	aerodynamic center of wing	Several
$(a.c.)_V$	aerodynamic center of the vertical panel	5.3.3.1
B	1. $\sqrt{1 - M^2 \cos^2 \Lambda_{c/4}}$	Several
	2. parameter accounting for changes in circulation	4.7 4.7.1
	3. number of propeller blades	9.1 9.1.1 9.1.3
B_{kn}	parameter in span-loading calculation	6.1.7
B_{vn}	parameter in span-loading calculation	6.1.7
$B_0, B_1, \ldots B_{15}$	drag-due-to-lift regression coefficients	4.3.3.2
B_2	parameter accounting for effect of control-surface and balance-chord ratios on hinge-moment derivative	6.1.6.1 6.1.6.2
b	1. difference in lift-curve slope, or $(C_{L_\alpha} \text{ at } M_{fb}) - (C_{L_\alpha} \text{ at } M_b)$	4.1.3.2
	2. surface span	Several

SYMBOL	DEFINITION	SECTIONS
	3. minor axis of elliptical-body cross section	4.2.1.2 4.2.2.2 4.2.3.1 4.2.3.2
	4. span of slot nozzle (normal to flow direction)	6.3.2
b'	propeller blade chord	9.1 9.1.1 9.1.3
b', b''	total spans of forward and aft surfaces, respectively	Several
$\bar{b}'$	average blade chord	9.1 9.1.1
b_E	span of trailing-edge extension of double-delta and cranked wings	4.1.3.2
b_H	total span of auxiliary horizontal surface, aft tail or canard	Several
b_{H_e}	total span of exposed horizontal tail	6.2.1.2
b_U	span of vertical panel below body center line	Several
b_{U_e}	span of exposed lower vertical panel	Several
b_V	1. span of vertical panel extended to body center line	Several
	2. span of vertical panel for twin vertical panels	5.3.1.1 5.6.1.1
b'_V	partial span of vertical panel for twin vertical panels (see Figure 5.3.1.1-24b)	4.5.1.1 4.5.1.2 5.3.1.1 5.6.1.1
b_{V_e}	span of exposed vertical panel	Several
b_{V_I}	span of vertical stabilizer (tip to fuselage)	Several
b_W	span of wing	Several
b'_W	effective span for unflapped wing	4.7 4.7.1
b_{bw}	span of basic wing	4.1.3.2 4.1.5.1 4.3.3.1 5.1.2.1

SYMBOL	DEFINITION	SECTIONS
b_e	total span of exposed surface	Several
b'_e, b''_e	total spans of exposed forward and aft surfaces, respectively	7.4.1.1
$(b_e)_i$, $(b)_e$	total span of exposed inboard panels of wing	4.3.2.2 4.3.3.1
b_{eff}	effective surface span	4.7 4.7.1 4.4.1
b'_{eff}	effective forward-surface span	4.5.1.1 7.4.1.1
b_f	total span of flaps or control surfaces, measured normal to the plane of symmetry	Several
b'_f	effective span for increment in load due to flaps	4.7 4.7.1
b_g	span of glove of double-delta and cranked wings	4.1.3.2 5.1.2.1
b_i	1. span of planform formed by two inboard panels	2.2.2 4.1.4.2 4.1.5.1 5.1.2.1
	2. total span of a given portion of main surface immersed in propeller slipstream, $2\sqrt{R_p^2 - (z_s + z_w)^2}$	4.6 4.6.1 4.6.3
b_{kk}	parameter in span-loading calculation	6.1.7
b_{max}	minor semiaxis of body cross section	4.2.3.1
b_o	span of planform formed by joining two outboard panels of wing	Several
b'_o	span of planform formed by joining two constructed outboard panels of wing	4.1.4.2 4.3.2.2 5.1.2.1
b_p	propeller blade width at any propeller span station	4.6 4.6.1
b_s	span of spoiler, on one wing panel	6.2.1.1 6.2.2.1
b_{slat}	total span of slats	6.1.4.3
b_v	span of the wing-tip vortices at a given longitudinal station behind a lifting surface	4.4.1 4.5.1.1 7.4.4.1

SYMBOL	DEFINITION	SECTIONS
b'_v, b''_v	vortex spans at the forward and aft surfaces, respectively	Several
b_{vn}	parameter in span-loading calculation	6.1.7
b_{vv}	parameter in span-loading calculation	6.1.7
$b_{v_{ru}}$	span of completely rolled up wing-tip vortices (at distances far downstream from lifting surface)	4.4.1 7.4.4.1
b_1, b_2	span of constructed panels of non-straight-tapered wings	4.1.3.2
b_1, b_2, b_3	vertical span of a given region as defined in Sketch (b) in Section 5.3.1.1	5.3.1.1 5.3.1.2
$b'_{.25,\ .50,\ \ldots}$	propeller blade chord at $\frac{r}{R} = 0.25, 0.50, \ldots$	9.1 9.1.1 9.1.3
$b/(2\ell)$, $\frac{b_W}{2\ell}$	wing slenderness parameter	Several
C	1. thickness correction factor for supersonic wing lift	4.1.3.3 4.1.3.4
	2. roll-moment-of-inertia correction factor for solid component	8.2
$(C_{LE})_{bw}$	leading-edge effect of basic wing on normal-force-curve slope	4.1.3.2
$(C_{LE})_g$	leading-edge effect of glove on normal-force-curve slope	4.1.3.2 4.1.3.4
C_a, C_b, C_c	wing parameters measured to plane of symmetry (see Figure 8.1-22)	8.1
C_0, C_1, ... C_{18}	regression coefficients as a function of Mach number	4.3.2.1
C_1, C_2	1. empirical taper-ratio constants	Several
	2. empirical constants that determine propeller downwash gradients	4.6 4.6.1 4.6.4
	3. Mach-number functions that determine thickness correction factors to supersonic flat-plate aerodynamic derivatives, $C_1 = \frac{2}{\sqrt{M^2 - 1}}$ $C_2 = \frac{(\gamma + 1) M^4 - 4 (M^2 - 1)}{2 (M^2 - 1)^2}$	Several
C_3	1. taper-ratio correction factor for wing aerodynamic center	4.1.4.3
	2. maximum lift-correction factor at transonic speeds	4.1.3.4

SYMBOL.	DEFINITION	SECTIONS
c	1. transonic wing lift-curve slope at M_{fb}	4.1.3.2
	2. chord of airfoil section	Several
	3. duct chord	9.3 9.3.1 9.3.2 9.3.3
	4. nozzle discharge coefficient	6.3.2
c'	1. effective chord of airfoil with deflected extensible-type flap (see Figures 6.1.1.1-44, -45, -46, -48, -51, and 6.1.5.1-60	Several
	2. airfoil chord measured perpendicular to the wing quarter-chord line	6.1.6.1 6.1.6.2
$\bar{c}$, $\bar{c}_W$	wing mean aerodynamic chord	Several
$\bar{c}'$	mean aerodynamic chord of the wing segment affected by the leading-edge device (see Sketch (h), Section 6.1.5.1)	6.1.5.1
$\bar{c}'$, $\bar{c}''$	mean aerodynamic chords of forward and aft surfaces, respectively	Several
c_B	chord at break span station	2.2.2 4.1.3.2 4.1.3.3
$\bar{c}_H$	mean aerodynamic chord of auxiliary horizontal surface, aft tail or canard	4.4.1 4.6 4.6.1 7.4.2.2
$\bar{c}_{H_e}$	mean aerodynamic chord of exposed horizontal-tail panel	4.5.3.1
c'_{LE}	airfoil chord with only leading-edge device extended	6.1.2.1 6.1.5.1
c_V	vertical tail chord at the distance z_H above body center line (see Figure 5.3.1.1-22b)	Several
$\bar{c}_{V_e}$	mean aerodynamic chord of exposed vertical-tail panel	4.5.3.1
$\bar{c}_{W_e}$	mean aerodynamic chord of exposed wing	4.5.3.1
c_a	hypothetical airfoil chord including trailing-edge flap extension and subtracting leading-edge flap extension	6.1.2.1 6.1.5.1
c'_a	extended wing chord due to complete forward-flap extension (see Figures 6.1.1.1-45, -46)	6.1.1.1
$\bar{c}_{\text{area not immersed}}$	mean aerodynamic chord of the wing area not immersed in the slipstream	4.6 4.6.3
c_{av}	average chord of airfoil	6.1.5.1
c_b	balance chord of a control or flap surface	6.1.3.1 6.1.3.2 6.1.6.1 6.1.6.2
c'_b	balance chord of control or flap surface measured perpendicular to the wing quarter-chord line	6.1.6.1

SYMBOL	DEFINITION	SECTIONS
c_{b_t}	chord of tab balance	6.1.3.1 6.1.3.2 6.1.3.3 6.1.3.4
c_{bw}	chord of basic wing	4.1.5.1 4.3.3.1
$\bar{c}_c$	mean aerodynamic chord of a particular control surface	6.3.4
$c_{c.p.}$	wing chord at spanwise center-of-pressure location	6.1.5.1
$\bar{c}_e$	1. mean aerodynamic chord of exposed panel	Several
	2. mean aerodynamic chord of elevator	6.3.4
$\bar{c}'_e$, $\bar{c}''_e$	mean aerodynamic chords of exposed forward and aft surfaces, respectively	7.4.1.1 7.4.1.2 7.4.4.1 7.4.4.2
c_f	flap or control chord measured parallel to plane of symmetry	Several
c'_f	flap or control chord measured perpendicular to the wing quarter-chord line	6.1.6.1
$\bar{c}_f$	mean flap chord	6.1.7
c_{f_i}	chord of a particular segment of a flap of n segments	6.1.2.1 6.1.5.1
$c_{f_{inc}}$	incompressible turbulent flat-plate skin-friction coefficient	4.2.3.1
$c_{f_{LE}}$	chord of the leading-edge flap	6 1.2.1 6.1.5.1
c_{f_r}	root chord of flap or control surface measured parallel to plane of symmetry	6.1.6.1
c_{f_t}	tip chord of flap or control surface measured parallel to plane of symmetry	6.1.6.1
c_{f_1}, c_{f_2}, c_{f_3}	effective chords of combined flap segments as defined by the principle of superposition, shown in Sketch (g), Section 6.1.2.1	6.1.2.1
$c_{f_{\perp LE}}$	chord of leading-edge flap perpendicular to leading edge of airfoil	6.1.5.1
c_i	average chord of that portion of wing immersed in propeller slipstream	4.6 4.6.1 4.6.3
$\bar{c}_i$	mean aerodynamic chord of inboard panel of wing	4.1.5.1 4.1.5.2
$(\bar{c}_i)_e$, $(\bar{c}_o)_e$	mean aerodynamic chords of exposed inboard and outboard panels, respectively, of wing	4.3.3.1
$\bar{c}_{i_H}$	mean aerodynamic chord of that portion of auxiliary surface immersed in propeller slipstream	4.6.3
$\bar{c}_o$	mean aerodynamic chord of outboard panel of wing	4.1.5.1 4.1.5.2 4.3.3.1
$\bar{c}_{p_e}$	mean aerodynamic chord of exposed tail panel	4.5.3.1
c_r	surface root chord	Several

SYMBOL	DEFINITION	SECTIONS
c_r', c_r''	root chords of forward and aft surfaces, respectively	4.5.2.1 7.4.1.1
c_{r_B}	root chord of basic triangular wing (see Sketch (a), Section 7.1.1.1)	5.1.3.1 7.1.1.1 7.1.4.2
$c_{r_{bw}}$	root chord of basic wing of double-delta and cranked wings	4.1.5.1 4.3.3.1 5.1.2.1
c_{r_E}	root chord of trailing edge extension of double-delta and cranked wings	4.1.3.2
c_{r_e}	root chord of exposed surface	Several
c'_{r_e}, c''_{r_e}	root chords of exposed forward and aft surfaces, respectively	4.5.1.2 7.4.1.1
$(c_{r_e})_H$	root chord of exposed horizontal surface	5.3.1.2
$(c_{r_e})_i$	root chord of exposed inboard panels of wing	4.3.2.2
c_{r_f}	root chord of control surface	6.1.5.1
c_{r_g}	root chord of glove of double-delta and cranked wings	4.1.3.2 5.1.2.1
c_{r_H}	root chord of horizontal stabilizer	8.1
c_{r_i}	root chord of inboard panel of wing	4.1.4.2 4.1.5.1 4.3.2.2
$(c_{r_i})_e$	root chord of inboard panel (exposed) of wing	4.3.3.1
c_{r_o}	root chord of outboard panel of wing	4.1.4.2 4.1.5.1 4.3.3.1
c'_{r_o}	root chord of constructed outboard panel of wing	4.1.4.2 4.3.2.2
c_{r_V}	root chord of vertical stabilizer (at fuselage)	8.1
c_{r_W}	root chord of wing	Several
c_{r_1}, c_{r_2}	root chords of constructed panel of non-straight-tapered wings	4.1.3.2
c_s	chord of spoiler	6.2.1.1 6.2.2.1
c_t	1. tip chord of surface	Several
	2. chord of tab, aft of hinge line	6.1.3.1 6.1.3.2 6.1.3.3 6.1.3.4
$\bar{c}_{tc}$	mean aerodynamic chord of control tab	6.3.4
$(c_{t_e})_i$	tip chord of exposed inboard panels of wing	4.3.2.2

SYMBOL	DEFINITION	SECTIONS
c_{t_H}	tip chord of horizontal stabilizer	8.1
c_{t_i}	tip chord of inboard panel of wing	4.1.4.2 4.3.3.1
c_{t_o}	tip chord of outboard panel of wing	4.1.4.2 4.3.2.2
c_{t_V}	tip chord of vertical stabilizer	8.1
c_{t_W}	tip chord of wing	4.1.3.2 5.1.2.1
$c_{\delta\delta}$	extended wing chord due to deflection of leading-edge and trailing-edge flaps (see Sketch (f), Section 6.1.2.1)	6.1.2.1 6.1.5.1
$(c')_{\eta_i}, (c')_{\eta_o}$	effective chords of airfoil with deflected extensible-type flap, at the inboard and outboard edge, respectively, of the flap	6.1.5.1
c_1, c_2	chords of forward and aft flaps, respectively, of a double-slotted flap	6.1.1.1
c_1, c_2, c_3	intersecting flap chord segments that approximate the mean-camber-line distribution of the flap components (see Sketch (e), Section 6.1.2.1)	6.1.2.1 6.1.5.1
$\Delta c_1, \Delta c_2, \Delta c_4, \Delta c_6$	terms analogous to section lift coefficients used in calculating section pitching moments	6.1.2.1 6.1.5.1
$\Delta c_{5_1}, \Delta c_{5_2}, \Delta c_{5_i}$	terms analogous to section lift coefficients for the first, second, and i^{th} trailing-edge flap segments, respectively	6.1.2.1 6.1.5.1
c_1'	flap chord of the forward-flap segment; i.e., for a broken trailing edge the forward-flap segment is extended to form a complete airfoil (see Figure 6.1.1.1-46)	6.1.1.1
$(\bar{c}/4)_V$	the quarter-chord point of the MAC of the vertical panel extending to body center line	Several
$(\bar{c}/2)_{V_e}$	50-percent-chord point of the MAC of exposed vertical panel	5.3.2.1 5.3.3.1
$(\bar{c}/4)_W$	the quarter-chord point of the MAC of the total wing	Several
D	1. total drag	2.1 4.7
	2. empirical factor used in calculating wing lift at high angles of attack	4.1.3.3
	3. diameter of a hemisphere	8.2
	4. propeller diameter	Several
	5. drag force	4.1.3
D′	base diameter of spherical-segment shell	8.2
D_o	body diameter	4.6.4
D_1'	nozzle-exit diameter	4.6.4
d	1. maximum fuselage diameter	Several
	2. $\frac{\tan \Lambda_{TE}}{\beta}$	6.1.6.1

SYMBOL	DEFINITION	SECTIONS
	3. average maximum diameter of fuselage	8.1
	4. outside diameter of a hollow cylindrical element	8.2
	5. equivalent-cylinder diameter for a hemisphere	8.2
	6. base diameter of a spherical nose segment or given frustum	4.2.2.1 4.2.3.1 7.2.1.1 7.2.1.2
	7. average body diameter at the exposed wing root	Several
	8. maximum diameter of forebody or afterbody	4.2.3.1
	9. 2/3 root chord of basic triangular wing	7.1.1.1 7.1.1.2 7.1.4.2
	10. maximum body height at wing-body intersection	5.2.1.1
d', d''	body diameters at the midchord points of the MAC of the forward and aft surfaces, respectively	4.4.1 4.5.1.1 4.5.1.2 7.4.1.1
d_{CB}	duct center-body diameter at exit plane	9.3 9.3.1 9.3.2 9.3.3
d_H	average fuselage width in region of horizontal tail	6.2.1.2
d_{LE}	diameter of leading edge	6.3.1 6.3.2
d_a	diameter at forward end of missile component	8.2
d_b	1. base diameter of body	Several
	2. diameter at aft end of missile component	8.2
	3. base diameter of jet nozzle	4.6.4
$(d_b)_{equiv}$	equivalent base diameter of a non-body-of-revolution configuration	4.2.3.1
d_{cyl}	diameter of cylinder	4.2.1.2 4.2.2.1
d_e	1. average maximum diameter of engine	8.1
	2. exit diameter of duct or nozzle	Several
d_{equiv}	equivalent diameter of a non-body-of-revolution configuration	4.2.1.2 4.2.3.1
$(d_{equiv})_{av}$	average equivalent diameter of non-body-of-revolution configuration	5.2.2.1
d_j	diameter of nozzle exit	4.6.4
d_{max}	maximum diameter of body	4.3.3.1 4.5.3.1

SYMBOL	DEFINITION	SECTIONS
d_n	base diameter of one of n segments of a body	4.2.3.1
d_o	1. base diameter of a spherically blunted body nose	4.2.3.1
	2. theoretical effect of blowing on lift derivative	6.1.4.1
d_p	diameter of ducted propeller	9.3 9.3.1
d_s	diameter of sphere for spherically blunted body noses	Several
d_t	width of nozzle throat	6.3.2
d_0	inside diameter of a hollow cylindrical element	8.2
d_1	upstream pressure interaction length	6.3.1
d_2	downstream interaction length	6.3.1
d_3	distance from reference line to point of intersection of two lines tangent to pressure curve (see Sketch (d), Page 6.3.1-9)	6.3.1
$d_1, d_2, d_3 \ldots$	diameter at aft end of given body segment	Several
$\frac{d}{b}$	ratio of maximum body width to wing span	4.3.2.1
E	empirical constant used in calculating wing lift at high angles of attack	4.1.3.3 4.1.3.4
$E''(\beta C)$	elliptical integral factors of the stability derivative	Several
e	1. Oswald (span) efficiency factor for induced drag	Several
	2. value of error	Several
e^*	induced span efficiency factor (inviscid)	4.1.5.2
e_H	Oswald (span) efficiency factor for induced drag of horizontal stabilizer	4.5.3.2
F	1. general force	4.1.3 8.1
	2. resultant force	4.7 9.2
F_c	1. control force	6.3.2
	2. control-column force (pull force positive)	6.3.4
F_{j_0}	vacuum thrust	6.3.2
F_p	rudder-pedal force (push on left pedal positive)	6.3.4
F_s	elevator stick force (pull force positive)	6.3.4
F_x	1. propeller-wing combination negative-drag force	9.2
	2. duct negative-drag force	9.3

SYMBOL	DEFINITION	SECTIONS
$F_w(\lvert y_{i,o} \rvert)$, $F_w(Y_{i,o})$, $F_{w,o}$	functions used to determine w	4.4.1
$F_1(N)$, $F_2(N)$, $F_3(N)$, $F_4(N)$, $F_5(N)$, $F_6(N)$, $F_7(N)$, $F_8(N)$, $F_9(N)$, $F_{11}(N)$	F(N) factors of the stability derivative	Several
F/T	thrust-recovery factor	9.2 9.2.1 9.2.3
f	1. fineness ratio of body	Several
	2. inflow factor of propeller	4.6 4.6.1
f_A	fineness ratio of body minus the nose	Several
f_C	fineness ratio of cylindrical segment of body	4.2.3.2
f_N	1. fineness ratio of body nose	Several
	2. fineness ratio of body nose and forebody	4.3.2.2
f_{N_o}	fineness ratio of spherically blunted cone extended to cone apex	4.2.3.1
f_b	fineness ratio of boattail	4.2.2.1
$(f)_{equiv}$	equivalent fineness ratio (see Equation 4.3.2.1-d)	4.3.2.2
f_f, $(f)_{forebody}$	fineness ratio of body forebody (see Sketch (a), Section 4.3.2.1)	4.3.2.2
f_{fus}	fineness ratio of fuselage	4.3.3.1
f_n, $(f)_{nose}$	fineness ratio of nose	4.3.2.2
G_c	main-control-surface stick gearing	6.3.4
$G_{c_{max}}$	maximum control-surface stick gearing	6.3.4
$G_{e_{max}}$	maximum elevator stick gearing	6.3.4
G_k, G_n, G_v	span-loading coefficients at spanwise stations k, n, and v, respectively	6.1.7
G_{tc}	control-tab stick gearing	6.3.4
$G(\beta C)$	elliptical integral factors of the stability derivative	7.1.1.1 7.1.1.2 7.1.4.1 7.1.4.2
$\frac{G}{\delta}$	subsonic spanwise loading coefficient	6.1.5.1 6.1.7
$\Delta \frac{G}{\delta}$	increment in spanwise loading coefficient	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{G}{\delta}\right)_v$	spanwise-loading coefficient at spanwise station v	6.1.7
$\left(\frac{G}{\delta}\right)_{\eta_i}, \left(\frac{G}{\delta}\right)_{\eta_o}$	spanwise loading coefficient at inboard and outboard ends, respectively, of a flap	6.1.5.1
g	$\frac{\tan \Lambda_{LE}}{\beta}$	6.1.6.1
g', g''	distances parallel to the plane of symmetry from panel apex to the forward end of the MAC of forward and aft panels, respectively	4.5.2.1
H	height of the quarter-chord point of the MAC of the wing above the ground plane	4.7 4.7.1 4.7.4
H_c	hinge moment of main control surface	6.3.4
H_H	height of the quarter-chord point of the MAC of the auxiliary horizontal surface above the ground plane	4.7 4.7.1
H_{tc}	hinge moment of control tab	6.3.4
h	1. average height of fuselage at the wing root chord	5.2.2.1 5.2.3.1 5.6.2.1 5.6.3.1
	2. downward displacement of trailing-vortex sheet from $z = 0$ plane (in this application $z = 0$ is chosen at the quarter-chord point of the MAC of the forward surface)	4.4.1 7.4.4.1
	3. altitude	4.6 4.6.1
	4. maximum height of sonic line above surface (effective jet height)	6.3.2
	5. average height above the ground of the quarter-chord point of wing chord of 75-percent semispan and the three-quarter-chord point of the wing root chord (see sketch on Figure 4.7.1-14)	4.7 4.7.1
h_H	height of aft-surface MAC quarter-chord point above or below the forward-surface root chord, measured in plane of symmetry normal to extended-forward-surface root chord, positive for the aft-surface MAC above the plane of the root chord	Several
$h_{c_r/4}$	height of the quarter-chord point of the wing root chord above the ground	4.7 4.7.1
h_d	distance of deflector lip below surface of wing, perpendicular to wing chord plane	6.2.1.1
h_s	1. distance of spoiler lip above surface of wing, measured from and normal to the airfoil mean line	6.1.1.1 6.2.1.1 6.2.2.1
	2. maximum height of separated boundary layer above the surface	6.3.2
h_v	distance of wing vortex above horizontal tail at tail center of pressure, measured normal to body axis	4.4.1

SYMBOL	DEFINITION	SECTIONS
h_1, h_2	fuselage depths as defined in Figure 5.2.3.1-8	5.2.3.1 5.6.3.1
$\frac{h}{d}$	ratio of maximum canopy height measured from body centerline to body height at the point of maximum canopy height	4.3.2.1
I	moment of inertia (see Figure 8.1-22)	8.1
I_{oy}	moment of inertia about centroidal axis of section	8.1
I_{oy}, I_{ox}, I_{oz}	pitching, rolling, and yawing moments of inertia, respectively, about the centroidal axis of the body	8.1
I_{sp}	jet vacuum specific impulse	6.3.2
$I_{v_{B(H)}}$	vortex interference factor for a lifting surface mounted on the body center line	6.2.1.2
$I_{v_{B(W)}}$	interference factor for effect of body vortex on horizontal panel	4.3.1.3 4.3.1.4
$I_{v_{B(W')}}, I_{v_{B(W'')}}$	interference factors for effects of body vortex on fore and aft panels, respectively	4.5.1.2
$I_{v_{W'(W'')}}$	interference factor for effect of forward panel vortex on aft panel	4.4.1 4.5.1.1 4.5.1.2 7.4.1.1
I_{xx}, I_{yy}, I_{zz}	moments of inertia of the vehicle about x-x axis, y-y axis, and z-z axis, respectively	8.2
$I_{xx}', I_{yy}', I_{zz}'$	moments of inertia of body component about x-x axis, y-y axis, and z-z axis, respectively	8.2
I_y, I_x, I_z	pitching, rolling, and yawing moments of inertia, respectively, about a remote axis	8.1
1	a particular segment of a trailing-edge flap of n segments	6.1.2.1 6.1.5.1
i', i''	angles of incidence of forward and aft surfaces, respectively	4.5.1.2 4.6.1 7.4.1.1
i_H	incidence of auxiliary horizontal surface, aft tail or canard, positive nose up	4.6 4.6.1 4.6.3 4.7.1
i_T	incidence of thrust axis, positive nose up	4.6 4.6.1 4.6.4
i_W	incidence of main surface, positive nose up	Several
Δi_v	total body vortices interference factor	5.3.1.2 5.6.1.2
i_{v_1}, i_{v_2}	body vortex interference factors	5.3.1.2 5.6.1.2

SYMBOL	DEFINITION	SECTIONS
J	1. empirical factor for estimating the lift of wings at high angles of attack	4.1.3.3 4.5.1.2
	2. ducted-propeller advance ratio, $\frac{V_\infty}{nd_p}$	9.3 9.3.1 9.3.2 9.3.3
	3. propeller advance ratio, $\frac{V_\infty}{nD}$	9.1 9.1.1 9.1.3 9.2
	4. jet momentum at the wing trailing edge, $m_j V_j$	6.1.1.1 6.1.4.1
J′	modified advance ratio, J cos α	9.1 9.1.1 9.1.3
J_{0_P}	advance ratio at zero power	9.1 9.1.3
J_{0_T}	advance ratio at zero thrust	9.1 9.1.1 9.1.3
j	one section of a wing of n sections having constant sweep angles within its boundary	4.1.3.2
K	1. factor used to estimate the maximum lift increment of a surface due to propeller power effects	4.6 4.6.2
	2. ratio of rolling-moment coefficient of a spoiler-slot-deflector to that of a plain spoiler	6.2.1.1
	3. parameter accounting for effective wing thickness	4.7 4.7.1
	4. factor accounting for the lift carry-over due to flap deflection on wing sections adjacent to flaps at subsonic speeds	6.1.5.1
	5. factor used to estimate the pitching effectiveness of trailing-edge flaps at transonic speeds	6.1.5.1
	6. surface-element pressure-coefficient constant	4.2.1.2 4.2.2.2
	7. apparent-mass factor	Several
	8. upstream amplification factor (control force normal to the surface normalized with respect to vacuum thrust of sonic nozzle)	6.3.2
	9. pitching-moment-of-inertia correction factor for solid component	8.2
	10. drag-due-to-lift factor	4.1.5.2
	11. ratio of extended wing chord, including extensions of both leading-edge and trailing-edge flaps, to retracted wing chord, $K = c_{\delta\delta}/c$	6.1.2.1
	12. theoretical correction factor for finite aspect-ratio effects on $c_{\ell_{\delta_f}}$, as defined in Equation 6.1.5.1-p	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
	13. constant factor for a given sharp-nosed airfoil section	4.1.5.1 4.3.3.1
	14. empirical correlation factor corresponding to lift-interference factor K_L	4.1.3.2
	15. empirical correlation factor depending upon planform geometry	6.2.2.1
	16. ratio of yawing-moment coefficient of spoiler-slot-deflector to that of a plain spoiler	6.2.2.1
	17. dimensionless correction factor used to extrapolate the potential-flow values to high lift coefficients	7.1.2.1 7.1.2.3
	18. number of propellers	9.2 9.2.1 9.2.3
K'	1. effective apparent-mass factor	Several
	2. flap-span factor	6.1.7
	3. empirical correction factor to section lift increment for nonlinear effects at high flap deflections	Several
K_A	wing-aspect-ratio factor	4.4.1 6.2.1.2
$K_{B(W)}$	ratio of the lift of the body in the presence of the wing to that of the wing alone	Several
K_D	propeller drag factor	4.6 4.6.4
K_H	1. factor accounting for relative size of horizontal and vertical tails	Several
	2. horizontal-tail-location factor	4.4.1 6.2.1.2
$K_{H(B)}$	apparent-mass factor of the horizontal tail in the presence of the body	Several
K_L	1. lift-interference factor for normal-force-curve slope	4.1.3.2 5.1.2.1
	2. pitch-moment-of-inertia correction factor for liquid mass	8.2
K_{M_Γ}	compressibility correction to the dihedral effect used in estimating C_{l_β}	5.1.2.1 5.2.2.1 5.6.2.1
K_{M_Λ}	compressibility correction to the sweep contribution used in estimating C_{l_β}	5.1.2.1 5.2.2.1 5.6.2.1
$K_{M_{\Lambda_i}}$, $K_{M_{\Lambda'_o}}$	compressibility correction to sweep contribution used in estimating C_{l_β} for constructed inboard and outboard panels, respectively, of a composite wing	5.1.2.1

SYMBOL	DEFINITION	SECTIONS
K_N	1. ratio of body-nose lift to that of wing alone	4.3.1.2 4.3.1.3 4.3.1.4 4.5.1.2
	2. propeller normal-force factor	4.6 4.6.1
	3. correlation factor for pressure drag of ogive noses	4.2.3.1 4.3.3.1 4.5.3.1
	4. empirical factor related to sideslip derivative C_{n_β} for body and wing-body interference	5.2.3.1 5.6.3.1
K_{R_ℓ}	empirical Reynolds-number factor	5.2.3.1
$K_{V(B)}$	apparent-mass factor of the upper vertical panel in the presence of the body	Several
$K_{V(BHU)}$	apparent-mass factor of the upper vertical panel in the presence of the body, horizontal tail, and lower vertical panel	Several
$K_{V(BU)}$	apparent-mass factor of the upper vertical panel in the presence of the body and lower vertical panel	Several
$K_{V(BW)}$	apparent-mass factor of the upper vertical panel in the presence of the body and wing	5.3.1.1
$K_{V(BWH)}$	apparent-mass factor of the upper vertical panel in the presence of the body, wing, and horizontal tail	Several
$K_{W(B)}$	1. ratio of the lift of the wing in the presence of the body to that of the wing alone	Several
	2. apparent-mass factor of the wing in the presence of the body	Several
$K_{(WB)}$	ratio of the lift of the wing-body combination to that of the wing alone	4.3.1.2 7.3.1.1 7.3.1.2 7.3.4.2
K_N', $K_{W(B)}'$, $K_{B(W)}'$	appropriate wing-body interference factors for the forward surface	Several
$K_{W(B)}''$, $K_{B(W)}''$	appropriate wing-body interference factors for the aft surface	Several
K_b	factor used in estimating the lift effectiveness of flaps and control surfaces at subsonic speeds	6.1.4.1 6.1.4.2 6.1.5.1 6.1.7
K_{b_k}, $K_{b_{k-1}}$	values of the span factor for outboard and inboard ends, respectively, of the k^{th} wing section	6.1.5.1
$(K_b)_{\eta_i}$, $(K_b)_{\eta_o}$	value of K_b due to a flap extending from the plane of symmetry to the inboard and outboard span stations, respectively, of the actual flap	6.1.4.1 6.1.4.2
K_f	factor used in estimating the body contribution to wing-body C_{l_β}	5.2.2.1 5.6.2.1
K_i	factor used to estimate the body contribution to wing-body C_{Y_β}	5.2.1.1 5.6.1.1
K_m	empirical nonlinear pitching-moment factor	4.1.4.3

SYMBOL	DEFINITION	SECTIONS
K_n	1. factor used to estimate the body contribution to wing-body C_{n_β}	5.2.3.1
	2. Knudsen number	4.2.3.1
K_o	upstream amplification factor of normal sonic nozzle	6.3.2
K_p	1. potential-flow lift parameter	4.2.1.2
	2. conversion factor for a partial-span flap on a sweptback wing	6.1.5.1
$(K_p)_{\eta_i}, (K_p)_{\eta_o}$	value of K_p due to a flap extending from the plane of symmetry to the inboard and outboard span stations, respectively, of the actual flap	6.1.5.1
K_t	hypersonic similarity parameter, $M\frac{t}{c}$, for a wing	4.1.5.1
K_v	viscous-flow lift parameter	4.2.1.2
K_α	factor accounting for the effect of control-surface span in the estimation of the parameter C_{h_α}	6.1.6.1
K_δ	factor accounting for the effect of control-surface span in the estimation of the parameter C_{h_δ}	6.1.6.2
K_θ	pressure-surface slope integral	4.2.1.2 4.2.2.2
K_Λ	1. empirically derived correction factor accounting for the effects of the wing planform	6.1.4.3
	2. flap-span factor	6.1.5.1
$(K_\Lambda)_{\eta_i}, (K_\Lambda)_{\eta_o}$	value of K_Λ due to a flap extending from the plane of symmetry to the inboard and outboard span stations, respectively, of the actual flap	6.1.5.1
K_λ	wing-taper-ratio factor	4.4.1 6.2.1.2
K_{ϕ_U}	cross-coupling interference factor of lower vertical surface	5.3.1.2 5.6.1.2
K_{ϕ_V}	cross-coupling interference factor of upper vertical surface	5.3.1.2 5.6.1.2
K_1	factor accounting for the effect of nacelles and fuselage on wing lift due to power effects	4.6 4.6.1
K_1, K_2, K_3	Mach-number functions used in determining supersonic flap pitching effectiveness	6.1.5.1
$K_1, K_2, K_3, \ldots$	empirical factors used in calculating moments of inertia	8.1
$K_1, K_2, \ldots K_{12}$	geometric and Mach-number parameters used in supersonic hinge-moment-derivation calculations (Page 6.1.6.1-7)	6.1.6.1
$K(A_1, C_J')$	correction factor for blown flaps as a function of jet momentum and aspect ratio	6.1.4.2
k	1. surface-roughness height	Several
	2. factor used in estimating supersonic parameter C_{h_α}	6.1.6.1
	3. the number of the wing section, numbered from fuselage center line outboard	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
	4. empirical factor used in estimating sideslip derivative C_{Y_β}	Several
	5. spanwise station, $\frac{m+1}{2}$	6.1.7
	6. factor used in determining the a.c. location of wing-lift carryover on the body, d/b	4.3.2.2
	7. tab spring effectiveness	6.3.4
$k_{B(H)}$, $k_{H(B)}$	tail-body interference factors	6.2.1.2
$k_{B(W)}$	ratio of lift-curve slope of body in presence of wing to that of wing alone, fuselage at zero angle of attack and wing incidence varying	4.2.1.1 4.3.1.2 4.3.1.3
$k_{W(B)}$	ratio of lift-curve slope of wing in presence of body to that of wing alone, fuselage at zero angle of attack and wing incidence varying	4.3.1.2 4.3.1.3
$k_{W(B)}'$, $k_{B(W)}'$, $k_{W(B)}''$, $k_{B(W)}''$	wing-body interference factors for the forward and aft panels, respectively	4.5.1.2
k_t	airfoil-theory thickness factor	6.1.1.1 6.1.1.2 6.1.4.1
k_1, k_2, k_3	empirical factors used in determining the maximum lift increment due to flap deflection	6.1.1.3 6.1.4.3
$(k_2 - k_1)$	apparent mass factor used in determining the subsonic lift and moment of bodies	Several
$k(\alpha)$	angle-of-attack correction to the horizontal-tail-body interference coefficient	5.2.1.2 5.3.1.2
L	1. general lift force	4.1.2 4.7
	2. equivalent-cylinder length for a hemisphere	8.2
	3. duct lift force, $L = C_L q_\infty S_D$	9.3 9.3.1 9.3.2
	4. airfoil-thickness-location parameter	4.1.5.1 4.3.3.1 4.5.3.1 7.4.2.2
	5. reference length	6.3.1
	6. distance of nozzle from plate leading edge	6.3.2
$L_{.75}$	left-blade position at 3/4-radius point	9.1 9.1.3
$\frac{L}{L_o} - 1$	parameter accounting for effect of image bound vortex on lift	4.7 4.7.1
$(LER)_i$, $(LER)_o$	leading-edge radius of the inboard and outboard panels, respectively, of a wing	4.1.5.2
$\frac{LER}{\bar{c}}$	ratio of leading-edge radius to mean aerodynamic chord taken at the mean aerodynamic chord	4.3.2.1

SYMBOL	DEFINITION	SECTIONS
ℓ	1. reference length	Several
	2. over-all length from wing apex to most aft point on the trailing edge	2.2.2 4.1.3.2 4.1.5.2 4.3.3.2
	3. control-surface linkage arm (see Sketch (f), Section 6.3.4)	6.3.4
ℓ''	distance parallel to longitudinal axis between quarter-chord point of MAC of total forward panel and quarter-chord point of MAC of total aft horizontal panel	Several
ℓ_A	1. length of body minus nose	Several
	2. length of afterbody (see Sketch (a), Section 4.3.3.2)	4.3.2.1 4.3.3.2
	3. length of the boattail segment of a jet nozzle	4.6.4
ℓ_B	1. total length of body	Several
	2. total length of body used as reference length in place of $\bar{c}$	7.2.1.1 7.2.1.2 7.2.2.1 7.2.2.2
	3. length of ogive-cylinder or cone-cylinder segment of body	4.2.2.1
ℓ_C	length of cylindrical segment of a body	4.2.1.1 4.2.1.2 4.2.3.1 4.2.3.2
ℓ_E	length of nozzle past afterbody	4.6.4
ℓ_F	length of flare	4.2.3.2
ℓ_H	1. longitudinal distance from quarter-chord point of the MAC of main surface to quarter-chord point of the MAC of the auxiliary horizontal surface, positive for auxiliary surface behind main surface	Several
	2. distance to the center of pressure of a horizontal stabilizer, measured parallel to the body center line, from the moment reference center	5.6.3.1
	3. distance from the moment reference center to the center of pressure of a horizontal-tail interference side force, measured parallel to the body center line	5.3.3.2 5.6.3.2
ℓ_N	1. length of body nose	Several
	2. length of body nose and forebody	4.3.2.1 4.3.2.2 4.3.3.2
ℓ_{N_o}	length of spherically blunted cone extended to cone apex	4.2.3.1
ℓ_U	distance to the center of pressure of the lower vertical stabilizer (ventral) measured parallel to the body center line, from the moment reference center	Several
ℓ_V	distance to the center of pressure of the upper vertical stabilizer, measured parallel to the body center line, from the moment reference center	Several
$\bar{\ell}_{W(B)}$	distance to center of pressure of the wing-induced body side force measured from the body nose, defined by Equations 5.2.3.2-c, -d	5.2.3.2
ℓ_a, ℓ_b	longitudinal distances from Z-axis to beginning and end stations of body component, respectively	8.2
ℓ_b	length of boattail	4.2.2.1
$\ell_{c.g.}$	longitudinal distance from beginning station of body component to the center of gravity of the component	8.2

SYMBOL	DEFINITION	SECTIONS
ℓ_e	length of engine including propeller	8.1
ℓ_{eff}	distance measured parallel to the forward-surface root chord, between the effective-forward-surface tip quarter chord point and the aft-surface MAC quarter-chord point	4.4.1 4.5.1.1 7.4.4.1
ℓ_{equiv}	length of equivalent body nose, f_{equiv} d	4.3.2.2
ℓ_f	1. longitudinal distance from nose of body to midpoint of wing tip	5.2.2.1 5.6.2.1
	2. length of body forebody	4.3.2.2
	3. length of control	6.3.1
ℓ_{f_i}	free interaction length	6.3.1
ℓ_h	distance from intersection of wing trailing edge with fuselage and the quarter-chord point of the MAC of the horizontal tail	4.2.2.1
ℓ_{r}	1. longitudinal distance from nose of body to exposed root chord of the wing	5.2.2.1 5.2.3.2
	2. length of body nose	4.3.2.2
ℓ_p	1. length of nacelle structure	8.1
	2. distance to the center of pressure of a panel in the empennage, measured parallel to the center line, from the moment reference center	Several
ℓ_s	separation length	6.3.1
ℓ_t	control-tab linkage arm (see Sketch (f), Section 6.3.4)	6.3.4
ℓ_x	distance from moment center to a transverse element, positive where element is forward of moment center	4.2.2.2
ℓ_0	distance from apex of forward-body theoretical cone to face of forward-body segment (see sketch, Page 7.2.1.1-5)	7.2.1.1 7.2.1.2
ℓ_1, ℓ_2	control-surface linkage arms (see Sketch (f), Section 6.3.4)	6.3.4
ℓ_1, ℓ_2, ℓ_3, ...	length of a given segment of a body	Several
ℓ_2	distance measured parallel to the forward-surface root chord, between the forward-surface root-chord aft end and the aft-surface MAC quarter-chord point	4.4.1 4.5.1.1 7.4.4.1
ℓ_3	distance measured parallel to the plane of symmetry, between the forward-surface MAC forward end and the root-chord aft end	4.4.1 4.5.1.1 7.4.4.1
M	1. Mach number	Several
	2. moment	2.1
	3. length of molecular mean tree path for rarefied gas	4.2.3.1
	4. duct pitching moment, $M = C_m q_\infty S_D c$	9.3 9.3.1

SYMBOL	DEFINITION	SECTIONS
ΔM	Mach-number increment	4.1.3.2
$(MAC)_{V_e}$	mean aerodynamic chord of exposed upper vertical panel	5.3.2.1
$M_{C_{D_{w_{peak}}}}{}_{\Lambda_{c/4} = n}$	Mach number for maximum wave-drag increment for swept wing with $\Lambda_{c/4} = n$	4.1.5.1 4.3.3.1 4.5.3.1
$M_{\Delta C_{D_{peak}}}$	Mach number for maximum wave-drag increment	4.1.5.1 4.3.3.1 4.5.3.1
$M_{\left(\frac{\partial C_D}{\partial M}\right)_{C_L = \text{const}} = 0.10}$	Mach number at which the numerical value of the slope of the curve of C_D vs M is 0.10	4.1.5.1
M_D	Mach number for drag divergence	4.1.5.1 4.2.3.1 4.3.3.1 4.5.3.1
$M_{D_{\Lambda_{c/4} = n}}$	Mach number for drag divergence for swept wing with $\Lambda_{c/4} = n$	4.1.5.1 4.3.3.1 4.5.3.1
M_I	initial drag-rise Mach number	4.5.3.1
M_N	Mach number determining if leading edge of wing is supersonic	4.1.5.1
M_a	1. Mach number used in estimating transonic lift-curve slope (see Page 4.1.3.2-13), $M_{fb} + .07$	4.1.3.2
	2. moment-area of a control surface about its hinge axis	6.1.6.1
M_b	Mach number used in estimating transonic lift-curve slope (see Page 4.1 3.2-13), $M_{fb} + .14$	4.1.3.2
M_c	1. Mach number normal to a circular cylinder in steady cross-flow, $M_\infty \sin \alpha$	4.2.1.2 4.2.2.2 4.2.3.2 4.3.3.2
	2. Mach number normal to a circular cylinder in steady cross-flow, $M_\infty \sin \alpha'$	5.2.1.2 5.3.1.2
	3. control-surface moment	6.3.4
M_{cr}	critical Mach number	7.1.1.2
M_e	nozzle-exit Mach number	6.3.2
M_{fb}	force-break Mach number	4.1.3.2 4.1.4.2 5.2.2.1 7.1.1.2
$(M_{fb})_\Lambda$	sweep correction for transonic force-break Mach number	4.1.3.2 4.1.4.2

SYMBOL	DEFINITION	SECTIONS
$(M_{fb})_{\Lambda=0}$	transonic force-break Mach number for zero sweep	4.1.3.2 4.1.4.2
M_o	slope of leading edge	4.4.1
M_p	propeller pitching moment	9.3.1
M_{tc}	tab-surface moment	6.3.4
M_α	local Mach number upstream of interaction	6.3.1
M_1	local Mach number	6.3.2
M_1'	Mach number at nozzle exit	4.6.4
M_∞	free-stream Mach number	Several
$M_\perp$	upstream Mach number normal to the leading edge of the wing	4.1.3.3
$(M_\perp)_{\alpha=0}$	upstream Mach number normal to the leading edge of wing at zero angle of attack	4.1.3.3
m	1. number of spanwise stations on full-span wing	6.1.7
	2. mass	8.1
	3. slope of lifting line	4.4.1
m, n	nondimensional chordwise stations in terms of c	2.2.2
$\dot{m}$	nozzle mass-flow rate	6.3.2
m_i	duct internal mass flow	9.3 9.3.1
m_j	mass flow rate of gas efflux (per section)	6.1.1.1
N	1. normal force	4.1.3
	2. propeller normal force	9.1
	3. ducted-propeller normal force	9.3 9.3.1
N_I	normal force acting at inlet of jet engine due to inclination of inlet to oncoming flow	4.6
N_p	propeller normal force	4.6 9.3.1
n	1. chordwise distance from the wing apex to the pitching-moment reference center measured in root chords, positive for reference center aft of apex	4.1.4 4.1.4.2 4.1.4.3
	2. chordwise distance from wing apex to moment reference center measured in wing mean aerodynamic chords, positive aft	4.7 4.7.3

SYMBOL	DEFINITION	SECTIONS
	3. number of engines	4.6 4.6.1
	4. nondimensional coordinate used in integration of wing-root and wing-tip conical pressures	6.1.6.1
	5. value of sweep angle	4.1.5.1
	6. distance from the face of a given body segment to the desired moment reference axis of the configuration	4.2.2.1 7.2.1.1 7.2.1.2
	7. spanwise station along wing	6.1.7
	8. propeller rotational speed, r.p.s.	9.1 9.3 9.3.1
	9. number of segments of trailing-edge flap	6.1.2.1 6.1.5.1
n'	load factor	4.6 4.6.4 6.3.4
n_i	distance of the desired moment reference center behind the forward face of any given body segment, positive for reference center aft of forward face	4.2.2.1
n_1, n_2	value of i at left- and right-hand wing tips of a swept wing, left and right as viewed from trailing edge to leading edge	4.4.1
P	pressure	6.3.1
P'	ratio of local pressure coefficient to two-dimensional pressure coefficient	6.1.6.1
P_P	plateau pressure	6.3.1
P_e	nozzle-exit pressure	6.3.2
P_o	pressure upstream of separation	6.3.1
P_s	separation pressure	6.3.1
P_α	local pressure upstream of interaction	6.3.1
P_{0_j}	jet plenum pressure	6.3.2
P_1	local pressure	6.3.2
P_2	1. pressure peak value	6.3.1
	2. plateau pressure	6.3.2
P_2'	upstream over-all pressure	6.3.2
P_3	pressure immediately downstream of a transverse jet	6.3.2
P_4	downstream over-all pressure	6.3.2

SYMBOL	DEFINITION	SECTIONS
P_∞	free-stream pressure	6.3.1 6.3.2
p	1. static pressure	Several
	2. cross-section perimeter	4.2.3.1
	3. planform-shape parameter, $S/(b\ell)$	2.2.2 4.1.3.2 4.1.5.2 4.3.3.2
	4. angular velocity in roll	Several
	5. total number of wing sections	6.1.5.1
Δp	static-pressure increment from ambient, $p - p_\infty$	4.6 4.6.1
P_{T_e}	total pressure at jet exit	4.6.1
p_b	base pressure	4.6.4
p_j	jet total pressure	4.6.4
p'_o	internal jet pressure	4.6.4
p_∞	free-stream ambient pressure	4.6.1 4.6.4
q	1. dynamic pressure	Several
	2. angular velocity in pitch	Several
q''	slipstream dynamic pressure	9.2
q_H	average dynamic pressure at an aft horizontal tail	Several
q_V	dynamic pressure at a vertical tail	7.4.2.1 7.4.2.2 7.4.2.3 8.1.2
q_p	average dynamic pressure acting on an aft panel	4.5.3.1
q_s	dynamic pressure in propeller slipstream	4.6
q_l	local dynamic pressure	6.3.2
q_∞	free-stream dynamic pressure	Several
q/p_t, $(q/p_t)_{rel}$	dynamic-pressure ratio for Prandtl-Meyer expansion	4.4.1
q/q_∞	average dynamic-pressure ratio	Several

SYMBOL	DEFINITION	SECTIONS
$\frac{q'}{q_\infty}$	average dynamic-pressure ratio acting on the forward surface	4.5.1.2
$\frac{q''}{q_\infty}$	average dynamic-pressure ratio acting on the aft surface	Several
$\frac{\Delta q}{q}$	dynamic-pressure-loss ratio for points not on the wake center line	4.4.1
$\frac{q_H}{q_\infty}$	effective dynamic-pressure ratio at horizontal tail	4.7 4.7.3
$\frac{\Delta q_H}{q_\infty}$	ratio of the change in dynamic pressure at the horizontal tail	4.6.3
$\frac{\Delta q_s}{q_\infty}$	ratio of the change from free-stream dynamic pressure to slipstream dynamic pressure to the free-stream dynamic pressure	4.6.1 4.6.3
$\left(\frac{\Delta q}{q}\right)_0$	dynamic-pressure-loss ratio at the wake center	4.4.1
R	1. Reynolds number	Several
	2. radial distance from thrust axis to centroid of incremental tail area	4.6.1
	3. reference radius of arbitrary body of revolution	4.2.1.2 4.2.2.2
	4. radius of hemisphere	8.2
	5. propeller radius	Several
	6. leading-edge-suction parameter defined as the ratio of the leading-edge suction actually attained to that theoretically possible	4.1.5.2 4.3.3.2
R'	leading-edge-suction parameter that accounts for the portion of the inboard panel submerged in the body	4.1.5.2
R_L	aerodynamic boost link ratio	6.3.4
$R_{L.S.}$	lifting-surface correlation factor	4.1.5.1 4.3.3.1 7.4.2.2
$(R_{L.S.})_H$	lifting-surface correlation factor of the horizontal-tail panel	4.5.3.1
$(R_{L.S.})_i$, $(R_{L.S.})_o$	lifting-surface correlation factor of the inboard panel and outboard panel, respectively, of the wing	4.3.3.1
$(R_{L.S.})_p$	lifting-surface correlation factor of the tail panel	4.5.3.1

SYMBOL	DEFINITION	SECTIONS
$(R_{L.S.})_V$	lifting-surface correlation factor of the vertical panel	4.5.3.1
$(R_{L.S.})_W$	lifting-surface correlation factor of the wing	4.5.3.1
R_{WB}	wing-body interference factor	4.3.3.1 4.5.3.1
R_b	base radius of body	4.6.4
R_{fus}	maximum fuselage radius forward of propeller plane	9.1 9.1.3
R_i, R_o	leading-edge suction parameter of inboard panel and outboard panel, respectively, of the wing	4.1.5.2
R_j	radius of jet exit	4.6 4.6.1
R'_j	radius of equivalent jet exit	4.6 4.6.1
R_ℓ	Reynolds number	Several
R_{ℓ_L}	Reynolds number based on length	6.3.2
$R_{\ell_{LER}}$	Reynolds number based on the leading-edge radius of the MAC	4.1.5.2 4.3.3.2
$\left(R_{\ell_{LER}}\right)_i$, $\left(R_{\ell_{LER}}\right)_o$	Reynolds numbers based on the leading-edge radius of the MAC of the inboard panel and outboard panel, respectively, of the wing	4.1.5.2
$R_{\ell_{MAC}}$, R_ℓ	Reynolds number based on the length of the mean aerodynamic chord	Several
$R_{\ell_{fus}}$	fuselage Reynolds number	4.3.3.1 4.5.3.1
R_{ℓ_s}	Reynolds number based on distance to the separation point	6.3.2
R_{ℓ_α}	local Reynolds number upstream of interaction	6.3.1 6.3.2
$R^*_{\ell_\alpha}$	reference Reynolds number upstream of interaction	6.3.1
$\left(R_{\ell_\alpha}\right)_{HL}$	Reynolds number at control hinge line, referred to local Reynolds number upstream of interaction	6.3.1

SYMBOL	DEFINITION	SECTIONS
$\left(R_{\ell_\alpha}\right)_{x_o}$	Reynolds number at the point of the beginning of interaction, referred to local Reynolds number upstream of interaction	6.3.1
$\left(R_{\ell_\alpha}\right)_{x_t}$	Reynolds number at transition point, referred to local Reynolds number upstream of interaction	6.3.1
R_{ℓ_∞}	free-stream Reynolds number	6.3.1 6.3.2
R_o	body radius	4.6.4
R_p	propeller radius	Several
R'_1	nozzle-exit radius	4.6.4
$R_{.75}$	right-blade position at 3/4-radius point	9.1 9.1.3
r	1. radius of base of body nose	4.3.1.3
	2. body radius at any station	Several
	3. radius of spherical nose segment	4.2.3.1
	4. body radius	4.3.1.2
	5. $\sqrt{1+\left(\frac{2h}{b}\right)^2}-\frac{2h}{b}$	4.7 4.7.1 4.7.4
	6. radius	8.1
	7. radial distance to propeller blade element	9.1 9.1.1 9.1.2 9.1.3
	8. angular velocity in yaw	Several
	9. average radius of body at vertical-tail exposed root chord	5.3.1.2
	10. average radius of body in the region of the horizontal tail	6.2.1.2
r'	nondimensional coordinate used in integrating wing-root and wing-tip conical pressures	6.1.6.1
r', r''	body radii at the midpoints of the exposed root chords of the forward and aft panels, respectively	4.1.5.2
$\bar{r}$	distance from the axis to the centroid of the total mass	8.1
$r_{LE_{bw}}$	leading-edge radius of basic wing	4.1.5.1 4.3.3.1
r_b	average radius of the body at the wing-body juncture	4.3.3.1
$(r)_{x_o}$	body radius at point where flow ceases to be potential	4.3.3.2

SYMBOL	DEFINITION	SECTIONS
r_1	1. radius of spherical body nose	4.2.1.1 7.2.1.1 7.2.1.2
	2. average body half-depth in the region of the tail panel(s), measured from center line	Several
r_2	average body half-width in the region of the tail panel(s), measured from center line	Several
$\frac{r}{b_W}$	ratio of body radius at exposed-wing-root quarter-chord point or midchord point of forward lifting surface to span of forward surface	4.3.1.3
$\frac{r'}{b'}$	ratio of body radius at root-quarter-chord point or midchord point of exposed forward lifting surface to span of forward surface	4.5.1.2
$\frac{r''}{b''}$	ratio of body radius at exposed-wing-root quarter-chord point at midchord point of aft lifting surface to span of aft surface	4.5.1.2
$(r_1/b)_U$	ratio of average body half-depth in the region of the lower vertical panel to span of lower vertical panel measured to body center line	Several
$(r_1/b)_V$	ratio of average body half-depth in region of the upper vertical panel to span of upper vertical panel measured to body center line	Several
$r_2 \Big/ \frac{b_H}{2}$	ratio of average body half-width in region of horizontal panel(s) to horizontal panel semispan	Several
S	1. cross-sectional reference area of the cylindrical portion of body	4.2.1.2 4.2.2.2
	2. cross-sectional area of body at any point x	4.3.3.1
	3. reference area	4.6 4.6.4 6.3.1
S, S_W	wing area	Several
S'	nose area of forebody or base area of afterbody	4.2.3.1
S', S''	gross planform areas of the forward and aft surfaces, respectively	Several
S_B	frontal area of body	Several
$(S_B)_{ref}$	body reference area	4.3.3.2 5.3.1.1
S_{B_S}	projected side area of body	5.2.1.2 5.2.3.1 5.6.3.1
S_D	duct planform area, $S_D = d_e c$	9.3 9.3.1 9.3.2 9.3.?

SYMBOL	DEFINITION	SECTIONS
S_E	area of trailing-edge extension of double-delta and cranked wings	4.1.3.2
S_H	area of auxiliary horizontal surface, aft tail or canard	Several
ΔS_H	incremental segments of horizontal-tail area	4.6.1
S_{H_e}	area of exposed horizontal-tail panel	4.5.3.1 6.2.1.2
S_{H_i}	area of portion of horizontal tail immersed in propeller slipstream	4.6.3
S_I	total surface area immersed in slipstream	4.6 4.6.4
S_J	streamwise basic wing area ahead of jet flap	6.1.5.1
S_L	area of a loaded region of wing in pressure-moment-area calculations	6.1.6.1
$S_{N_{ref}}$	base area of body nose, πr^2	Several
S_S	wetted or surface area of body excluding base area	Several
$(S_S)_e$	exposed wetted area of body (isolated body minus surface area covered by wing at wing-body juncture)	4.3.3.1 4.5.3.1
S_{U_e}	area of exposed lower vertical panel	Several
S_V	1. area of single vertical panel for configuration with twin vertical panels	5.3.1.1 5.6.1.1
	2. area of upper vertical panel measured to body center line	Several
S_{V_e}	area of exposed upper vertical panel	Several
S_W	wing area	Several
S_{W_e}	area of exposed wing	4.3.3.1 4.5.3.1
S_{W_f}	1. wing planform area including and directly forward of flap area (flap area not included) (see Section 2.2.2)	4.6 4.6.4 6.1.4.2 6.1.4.3
	2. flap-affected wing area, including increase in area due to flap extension	6.1.4.1 6.1.4.2 6.1.5.1
S_{W_i}	wing planform area including and directly forward of flap area immersed in propeller slipstream	4.6.4
S_b	body base area	Several
S_{bw}	area of basic wing	4.1.3.2 4.1.5.1 4.3.3.1 5.1.2.1

SYMBOL	DEFINITION	SECTIONS
$(S_{bw})_e$	area of exposed basic wing	4.3.3.1
S_c	main-control-surface area	6.3.4
S_e	1. area of exposed wing	Several
	2. area of elevator	6.3.4
	3. flow area at duct exit plane, $\frac{\pi d_e^2}{4}\left[1-\left(\frac{d_{CB}}{d_e}\right)^2\right]$	9.3.1
S'_e, S''_e	exposed planform areas of the forward and aft surfaces, respectively	Several
$(S_e)_i$	area of exposed inboard panel of wing	4.3.2.2
S_f	area of flap or control surface	6.1.4.1 6.1.5.1 6.2.1.1
S_g	area of glove of double-delta and cranked wings	4.1.3.2 5.1.2.1
S_i	1. total area of inboard panels of wing	Several
	2. area of portion of wing immersed in propeller slipstream, $b_i c_i$	Several
	3. primary-surface planform area forward of and including the flap area inside the primary-surface tip Mach cone (Figure 6.1.7-28b)	6.1.7
$(S_i)_e$, $(S_o)_e$	areas of exposed inboard and outboard panels, respectively, of wing	4.3.3.1
S_j	area of one section of wing of n sections	4.1.3.2 4.1.3.3
S_k	area of k^{th} wing segment with all flaps retracted	6.1.5.1
S_{ni}	primary-surface planform area forward of and including the flap area outside the primary-surface tip Mach cone (Figure 6.1.7-28b)	6.1.7
S_o	1. total area of outboard panels of wing	Several
	2. cross-sectional area at body station x_o	Several
S'_o	total area of constructed outboard panels of wing	4.1.4.2 4.3.2.2 5.1.2.1
S_p	1. body planform area	4.2.1.2 4.2.2.2 4.2.3.2 4.3.3.2
	2. propeller disk area, πR_p^2	Several
S_{ref}	reference area	Several

SYMBOL	DEFINITION	SECTIONS
S_t	total wing area, including increase in area due to flap extensions	6.1.4.1 6.1.4.2
S_{tc}	control-tab area	6.3.4
S_{wet}	wetted area	4.1.5.1 4.3.3.1 7.4.2.2
$(S_{wet})_e$	wetted area of exposed wing	4.3.3.1 4.5.3.1
$\left[(S_{wet})_H\right]_e$	wetted area of exposed horizontal-tail panel	4.5.3.1
$(S_{wet})_i, (S_{wet})_o$	wetted areas of inboard and outboard panels, respectively, of wing	4.1.5.1 4.3.3.1
$\left(S_{wet_i}\right)_e, \left(S_{wet_o}\right)_e$	wetted areas of exposed inboard and outboard panels, respectively, of wing	4.3.3.1
$\left[(S_{wet})_p\right]_e$	wetted area of exposed tail panel	4.5.3.1
$\left[(S_{wet})_V\right]_e$	wetted area of exposed vertical-tail panel	4.5.3.1
$\left[(S_{wet})_W\right]_e$	wetted area of exposed wing	4.5.3.1
S_x, $S(x)$	body cross-sectional area at any body station, πr^2	Several
S_1, S_2	area of constructed wing panels used to obtain wing lift-curve slope	4.1.3.2 5.1.2.1
S_1, S_2, S_3, . . .	areas on added vertical panel affected by Mach lines emanating from the intersection of exposed leading and trailing edges of all other panels with the body	Several
S_2, S_3	areas of constructed wing panels affected by jet flaps	6.1.5.1
S_{act}/S_{ext}	ratio of actual projected side area of fuselage to that of extended fuselage as determined by Mach lines emanating from leading and trailing edges of exposed root chord of the horizontal panel	Several
T	1. thrust per engine	Several
	2. temperature	6.3.1
	3. factor that accounts for the reduction in longitudinal velocity for wings of infinite span	4.7 4.7.1 4.7.4
	4. product of force and radius	8.1
	5. thrust per propeller or total thrust when used in thrust-recovery factor	9.1 9.1.2 9.2

SYMBOL	DEFINITION	SECTIONS
	6. ducted-propeller thrust	9.3 9.3.1
T_R	transition-strip indicator	4.3.2.1 4.3.3.2
T_{aw}	adiabatic wall temperature	6.3.1
T_c	1. thrust coefficient based on free-stream velocity and propeller disk area, $\frac{T}{q_\infty S_p}$	9.1 9.1.2 9.1.3
	2. propeller thrust coefficient based on free-stream velocity and wing area, $\frac{T}{q_\infty S}$	9.2 9.2.1 9.2.3
T'_c	thrust coefficient per engine, $\frac{2T}{\rho V_\infty^2 S_W}$	Several
T''_c	propeller thrust coefficient based on slipstream velocity and propeller disk area, $\frac{T}{q'' S_p}$	9.2 9.2.1 9.2.3
T_i	total internal axial thrust	9.3 9.3.1
T_{net}	ducted-propeller total net thrust, $(T_i - C_{D_e} q_\infty S_D)$	9.3 9.3.1
T_o	1. free-stream temperature	4.6.4
	2. hovering thrust	9.3.1
T'_o	internal jet temperature	4.6.4
T_p	propeller thrust	9.3.1
T_w	wall temperature	6.3.1
T_α	local temperature upstream of interaction	6.3.1
T_∞	free-stream temperature	6.3.1
t	airfoil maximum thickness	Several
t_c	thickness of control device at hinge line	6.1.3.1 6.1.3.2 6.1.6.1 6.1.6.2
$t_{c.p}$	nondimensional parameter used in calculating moment-arm parameter	6.1.6.1
$t/c, (t/c)_{av}$	average streamwise thickness ratio of lifting surface	Several
$\frac{t}{c'}$	airfoil thickness ratio, based on extended wing chord	6.1.1.1 6.1.1.2 6.1.4.1
$\left(\frac{t}{c}\right)'$	maximum airfoil thickness ratio measured normal to control-surface hinge line	6.1.6.1 6.1.6.2

SYMBOL	DEFINITION	SECTIONS
$\frac{t}{c}$	wing thickness ratio at mean aerodynamic chord	4.3.2.1
$(t/c)_{bw}$	average thickness of the basic wing	4.3.3.1
$(t/c)_{eff}$	effective thickness ratio	4.1.5.1 4.3.3.1 4.5.3.1
$(t/c)_i$, $(t/c)_o$	average streamwise thickness ratios of inboard and outboard panels, respectively, of a lifting surface	4.1.5.1 4.3.3.1
$(t/c)_{max}$	maximum thickness ratio	4.1.3.4 4.5.3.1 4.7
$(t/c)_p$	thickness ratio of tail panel	4.7.1 4.5.3.1
V, V_∞	free-stream velocity	Several
$\overline{V}$	transonic velocity similarity parameter, $\frac{\beta^2}{\left(\frac{t}{c}\right)^{2/3}}$	4.1.4.2
V_B	total body volume	Several
V_N	volume of nose	7.3.1.1
V_T	vertical-tail indicator	4.3.2.1
V_e	1. duct exit velocity	9.3 9.3.1
	2. nozzle exit velocity	6.3.2
	3. equivalent airspeed	6.3.4
V_i	velocity increment of internal mass flow due to power	9.3 9.3.1
V_{i_o}	internal mass-flow velocity with power off	9.3
V_j	1. jet exit velocity	4.6 4.6.1
	2. velocity of gas efflux leaving the trailing edge of the airfoil	6.1.1.1
V'_j	equivalent jet-exit velocity	4.6 4.6.1
$\frac{V_e}{V_\infty}$	exit-velocity ratio	9.3 9.3.1 9.3.2
v	1. any spanwise station on wing	9.3.3 6.1.7
	2. induced-drag factor	4.1.5.2 4.3.3.2

SYMBOL	DEFINITION	SECTIONS
W	weight	4.6 4.6.4 6.3.4 8.2
W_H	weight of horizontal-stabilizer section	8.1
W_L	wing-location index	4.3.2.1
W_P	weight of power-plant section	8.1
W_V	weight of vertical stabilizer	8.1
W_W	weight of wing section including wing carry-through structure	8.1
W_e	weight of engine and propeller	8.1
W_f	weight of fuselage section	8.1
W_{fs}	weight of fuselage structure	8.1
w	1. average body width at the exposed-wing or exposed-tail root chord	5.2.2.1 5.6.2.1
	2. maximum body width	4.3.1.4 5.2.3.1 5.6.3.1
	3. factor used to determine the downwash gradient at a particular point in the flow field not close to the trailing edge of the wing	4.4.1
	4. weight per unit length of element	8.2
	5. induced drag factor	4.1.5.2 4.3.3.2
	6. local vertical disturbance velocity	7.1.1.2
w_a, w_b	weights per unit length at beginning and end stations of body component, respectively	8.2
X	axial force	4.1.3
$\overline{X}$	longitudinal distance of vehicle center of gravity from nose apex	8.2
x	1. distance along airfoil chord, origin at LE	2.2.1 2.2.2 6.1.2.1 6.3.1
	2. distance between the moment center and the a.c. of the lifting surface affected by downwash, positive when a.c. is ahead of moment center	4.5.1.1
	3. parameter accounting for effect of image trailing vortex on lift	4.7 4.7.1

SYMBOL	DEFINITION	SECTIONS
	4. distance of centroid of the area affected by jet power effects from moment reference center, positive for area forward of reference center	4.6.3
	5. distance of the local center of pressure aft of the quarter-chord of the MAC (see Equation 6.1.5.1-j)	6.1.5.1
	6. longitudinal distance from the nose to quarter-chord point of the MAC of the exposed wing panel	4.3.1.3
	7. any station along body	Several
	8. longitudinal distance measured from the wing-root trailing edge aft	4.4.1 7.4.1.1
	9. longitudinal coordinate measured forward from wing leading edge	9.1 9.1.3
	10. longitudinal distance from the body nose to midchord point of the MAC of exposed vertical panel	5.3.1.2 5.6.1.2
	11. distance of origin of moments from the 2/3 c_{r_B} point of the basic triangular wing, measured along the longitudinal axis, positive ahead of the 2/3 c_{r_B} point	5.1.3.1 7.1.1.1
	12. distance of origin of moments from the wing midchord point, measured along the longitudinal axis, positive ahead of midchord point	5.1.3.1
	13. distance of center of loading of a conical-flow region from control hinge axis measured normal to the hinge axis	6.1.6.1
	14. longitudinal distance measured from vertical-tail leading edge to projected quarter-chord of horizontal-tail MAC on to root chord (see sketch, Figure 5.3.1.1-22b)	5.3.1.1 7.4.2.1 7.4.2.2 7.4.2.3
	15. distance from body nose to quarter-chord point of the MAC of exposed horizontal tail in subsonic flow	6.2.1.2
	16. distance from body nose to midchord point of the MAC of exposed horizontal tail in supersonic flow	6.2.1.2
	17. distance from nose to center of pressure of given body segment	4.2.2.1
Δx	1. increment between successive longitudinal stations	4.2.3.2 4.3.3.1 6.1.7
	2. the chordwise distance from the quarter-chord point of the 75-percent-semispan chord to the three-quarter-chord point of the wing root chord, positive when the latter is aft of the former (see Figure 4.7.1-14)	4.7 4.7.1
	3. distance between forward and aft faces of given body segment	4.2.2.1
x'	stations measured from leading to trailing edge of airfoil surface	4.4.1
x', x''	longitudinal distances used in estimating wing pitching moment	4.5.2.1

SYMBOL	DEFINITION	SECTIONS
x', z'	corresponding point on the airfoil for a point x, z in the flow field	4.4.1
x''	location of quarter-chord point of MAC of total aft horizontal panel	7.4.1.1 7.4.1.2 7.4.4.1 7.4.4.2
$\bar{x}$	1. distance between a.c. and c.g., positive when c.g. is ahead of a.c.	Several
	2. longitudinal distance from axes origin to c.g. of component	8.2
	3. chordwise distance between duct moment reference center and installed duct center of pressure, positive for center of pressure ahead of moment reference center	9.3 9.3.2
x_H	distance between vehicle center of gravity and quarter-chord point of horizontal stabilizer MAC (see Figure 4.5.3.2-4)	4.5.3.2
x'_H	distance from jet wake origin to the quarter-chord point of the MAC of the horizontal tail, parallel to the thrust axis	4.6 4.6.1
x_{HL}	distance from nose of configuration to control hinge line	6.3.1
x_I	longitudinal distance between jet inlet and quarter-chord point of wing MAC	4.6 4.6.1 4.6.3
x_{LE}	longitudinal distance from aircraft reference-axis origin to leading edge of mean aerodynamic chord of wing segment affected by leading-edge device	6.1.5.1
$\bar{x}_{LE}$	chordwise distance from apex to leading edge of MAC	2.2.2
x_{MRP}	distance from the leading edge of MAC to the moment reference point, positive for the moment reference point aft of the leading edge of the MAC	6.1.5.1
x_R	point of reattachment pressure rise (see Sketch (a), Page 6.3.1-2)	6.3.1 6.3.2
x_W	longitudinal distance from aerodynamic center of that portion of wing immersed in propeller slipstream to moment-reference-center location, positive for a.c. forward of moment reference center.	4.6 4.6.3
x_a	center-of-lift location of incremental load due to flap deflection, measured positive aft from extended airfoil leading edge parallel to free stream	6.1.2.1
$x_{a.c.}$	1. distance between aerodynamic center and wing apex, parallel to the MAC, positive for a.c. aft of wing apex	Several
	2. airfoil section a.c. position	4.1.2.2
	3. distance between aerodynamic center and airfoil leading edge, parallel to free stream, positive for aerodynamic center aft of leading edge	6.1.2.1
$\Delta x_{a.c.}$	shift in wing aerodynamic center at transonic speeds due to flow separation	4.1.4.2
$x'_{a.c.}$	aerodynamic center of the forward panel, referred to forward-panel apex	4.3.2.2 4.5.2.1
$x''_{a.c.}$	aerodynamic center of the aft panel, referred to aft-panel apex	4.5.2.1
$(x'_{a.c.})'_o$	aerodynamic center of the constructed outboard panel of the wing	4.3.2.2
$(x_{a.c.})_p$	distance between quarter-chord point of MAC of added panel and aerodynamic center of added panel. For supersonic case the distance between the mid-chord point of MAC and aerodynamic center	5.3.3.1 5.6.3.1

SYMBOL	DEFINITION	SECTIONS
$(x_{a.c.})_V$	distance between quarter-chord point of MAC of vertical panel and aerodynamic center of vertical panel	5.3.3.1
x_c	1. axial distance from vertex of body nose to centroid of body planform area	Several
	2. location of hinge line (for corner flow)	6.3.1
	3. fore and aft displacement of control column, positive forward	6.3.4
$x_{c_{max}}$	maximum displacement of control column, positive forward	6.3.4
$x_{centroid}$	distance of the centroid of area of a wing behind the wing apex, parallel to wing MAC and plane of symmetry	2.2.2
$x_{c.g.}$	1. distance between center of gravity and quarter-chord point of wing MAC, parallel to MAC, positive for c.g. aft of MAC	4.5.2.1 4.6 5.3.3.1 7.1.3.3
	2. distance from wing apex to center of gravity, parallel to MAC, positive for c.g. aft of wing apex	Several
$x_{c.p.}$	1. distance from wing apex to center of pressure, parallel to wing chord and plane of symmetry, positive for c.p. aft of wing apex	4.1.4 4.3.2.2
	2. distance from body nose to body center-of-pressure location, positive aft	4.2.2.1 5.2.3.2
	3. distance from airfoil leading edge to center of pressure of incremental load due to flaps, parallel to wing chord, positive for center of pressure aft of leading edge	6.1.2.1
	4. chordwise center-of-pressure location aft of the leading edge for a flapped wing section	6.1.5.1
	5. center-of-pressure location measured relative to the leading edge (two dimensional)	6.3.2
	6. chordwise distance from duct leading edge to center of pressure of unstalled duct, positive aft of duct leading edge	9.3 9.3.2
$x_{c.p._b}$	chordwise center-of-pressure location aft of the leading edge for the basic loading of a plain flap	6.1.5.1
$(x_{c.p.})_b$	center-of-pressure location of boattail, measured aft of the forward face of the boattail	4.2.2.1
$(x_{c.p.})_{\Delta C_N}$	distance of center of pressure of normal-force increment from moment reference point, negative aft	6.3.1
x_{c_V}	parameter accounting for relative positions of the horizontal and vertical tails	5.3.1.1
$(x_{\bar{c}/4})_V$	longitudinal distance between quarter-chord point of MAC of vertical panel and the forward end of its root chord	5.3.3.1
x_e	location of nozzle exit (see Sketch (a), Page 6.3.2-3)	6.3.2
x'_e	distance from jet exit to the quarter-chord point of the MAC of the horizontal tail, parallel to the thrust axis	4.6 4.6.1
x_f	1. distance from airfoil leading edge, parallel to free stream, where total lift increment due to flaps acts	6.1.2.1
	2. distance of the leading edge of the control root chord behind the wing axis of pitch	6.1.5.1
$\bar{x}_f$	longitudinal centroidal distance of fuselage from nose	8.1
$x_{f_1}, x_{f_2}, x_{f_i}$	center-of-lift location of incremental load due to deflection of first, second, and i^{th} flap segment, respectively, measured aft from airfoil leading edge parallel to free stream	6.1.2.1 6.1.5.1

SYMBOL	DEFINITION	SECTIONS
$x_{i(\alpha)}$	distance to center of pressure of wing-induced body side force from juncture of wing leading edge and body at angle of attack	5.2.3.2
$x_{i(\alpha = 0)}$	distance to center of pressure of wing-induced body side force from juncture of wing leading edge and body at zero angle of attack	5.2.3.2
x_j	distance from airfoil leading edge, parallel to free stream, where total lift increment due to jet efflux acts	6.1.2.1 6.1.5.1
x_j'	longitudinal distance from jet wake origin to jet exit, usually considered to be 4.6 times the orifice exhaust radius	4.6 4.6.1
Δx_k	longitudinal distance from moment reference center to chord for zero sweep, defined in x_m definition 4 below, for the k^{th} wing segment	6.1.5.1
x_m	1. longitudinal distance from the body nose to the chosen moment center, positive aft	Several
	2. chordwise distance from duct leading edge to moment reference center, positive aft of duct leading edge	9.3 9.3.2
	3. desired pitching-moment reference point measured positive aft from basic airfoil leading edge paralel to wing chord	6.1.2.1 6.1.5.1
	4. distance from wing leading edge to unique unswept reference line so that the ratio of x_m to local cnord is constant for straight-tapered wings (see Sketch (κ), Section 6.1.5.1)	6.1.5.1
x_o	1. body station where flow ceases to be of a potential nature	Several
	2. function of the slope of the lifting line (m), $\frac{mx}{b/2}$	4.4.1
	3. beginning of pressure interaction	6.3.1
x_p	1. longitudinal distance from intersection of propeller plane with thrust axis and the quarter-chord point of the MAC of the wing	4.6 4.6.1 4.6.3
	2. fore and aft displacement of right rudder pedal, positive forward	6.3.4
x_r	distance from forward end of root chord to intersection of control hinge line with root chord, parallel to wing root chord	6.1.6.1
Δx_r	distance from wing apex to desired moment reference center, measured positive aft	6.1.5.1
x_{ref}	desired pitching-moment reference point, measured positive aft from basic airfoil leading edge parallel to wing chord	6.1.2.1
x_s	1. longitudinal distance from model vertex to point of vortex separation	4.3.1.3 5.3.1.2 5.6.1.2 6.2.1.2
	2. distance from nose of airfoil to spoiler lip, parallel to wing chord (Figure 6.1.1.1-52b)	6.1.1.1 6.2.1.1 5.2.2.1
	3. point of separation pressure rise (see Sketch (a), Page 6.3.1-2)	6.3.1 6.3.2

SYMBOL	DEFINITION	SECTIONS
x_s'	distance from wing leading edge to spoiler hinge line (see Sketch (g), Page 6.2.1.1-6)	6.2.1.1
x_t	1. chordwise position of airfoil maximum thickness	2.2.1 4.1.5.1 4.3.3.1
	2. distance from forward end of tip chord to intersection of control hinge line with tip chord, parallel to root chord	6.1.6.1
	3. transition distance	6.3.1
$x_{(y_c)_{max}}$	chordwise position of maximum camber of airfoil	2.2.1
x_1	1. body station where $\frac{dS_x}{dx}$ first reaches its maximum negative value	Several
	2. distance from intersection of wing leading edge or trailing edge with fuselage and the center of pressure of given body segment (see Sketch (a))	4.2.2.1
$\bar{x}_1$	distance from intersection of wing leading edge with fuselage to forward face of body segment adjacent to the intersection (see Sketch (a))	4.2.2.1
x_1, x_2, x_3	distance parameters used to define section thickness-ratio factor for hexagonal airfoils	4.1.5.1 4.3.3.1
x_1, x_2, x_6	moment arms corresponding to section lift terms Δc_1, Δc_2, Δc_6, respectively	6.1.2.1 6.1.5.1
x_3	point of beginning of downstream pressure rise (see Sketch (a), Page 6.3.2-3)	6.3.2
x_4	point of peak downstream pressure rise (see Sketch (a), Page 6.3.2-3)	6.3.2
$x_{5_1}, x_{5_2}, (x_5)_i$	moment arms corresponding to section lift terms Δc_{5_1}, Δc_{5_2}, Δc_{5_i}, respectively, for the first, second and i^{th} flap segments, respectively	6.1.2.1 6.1.5.1
$\frac{x}{c_v}$	parameter accounting for relative positions of horizontal and vertical tails	5.3.1.1 5.6.1.1
$\frac{x_{a.c.}}{\bar{c}}$	distance of aerodynamic center of wing aft of wing apex, measured in mean aerodynamic chords, positive aft	4.1.4.3
$\frac{x_{a.c.}}{c_r}$	distance of aerodynamic center of wing aft of wing apex measured in root chords, positive aft	4.1.4.2 4.1.4.3 4.3.2.2

SYMBOL	DEFINITION	SECTIONS
$\frac{\Delta x_{a.c.}}{c_r}$	incremental a.c. location accounting for separation effects	4.1.4.2
$\left(\frac{x_{a.c.}}{c_r}\right)_{B(W)}$	value of parameter for body in presence of wing	4.3.2.2
$\left(\frac{x_{a.c.}}{c_r}\right)_{C_L=0}$	aerodynamic-center location at zero lift	4.1.4.3
$\left(\frac{x_{a.c.}}{c_r}\right)_i$	distance of a.c. location of inboard panel of wing aft of apex of inboard panel measured in its root chords	4.1.4.2
$\left(\frac{x_{a.c.}}{c_r}\right)_N$	value of parameter for body nose	4.3.2.2
$\left(\frac{x_{a.c.}}{c_r}\right)_o$	distance of a.c. location of outboard panel of wing aft of the apex of outboard panel, measured in its root chords	4.1.4.2
$\left(\frac{x_{a.c.}}{c_r}\right)_o'$	distance of a.c. location of constructed outboard panel of wing aft of the apex of the constructed outboard panel, measured in its root chords	4.1.4.2 4.3.2.2
$\left(\frac{x_{a.c.}}{c_r}\right)_{W(B)}$	value of parameter for wing in presence of body	4.3.2.2
$\frac{x_{a.c.}'}{c_{r_e}}$	distance of aerodynamic center of wing-body configuration from apex of exposed wing, measured in exposed-wing root chords	4.3.2.2
$\left(\frac{x_{a.c.}'}{c_{r_e}}\right)_{B(W)}$	distance of aerodynamic center of body in presence of the wing from apex of exposed wing, measured in exposed-wing root chords	4.3.2.2
$\left(\frac{x_{a.c.}'}{c_{r_e}}\right)_i$	distance of aerodynamic center of inboard panel of wing from apex of exposed wing, measured in its exposed-wing root chords	4.3.2.2
$\left(\frac{x_{a.c.}'}{c_{r_e}}\right)_N$	distance of aerodynamic center of body nose ahead of wing-body juncture from apex of exposed wing, measured in exposed-wing root chords	4.3.2.2

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{X_{a.c.}}{C_{r_e}}\right)_W$	value of parameter for wing	4.3.2.2
$\left(\frac{X_{a.c.}}{C_{r_e}}\right)_{W(B)}$	distance of aerodynamic center of exposed wing in presence of the body from apex of exposed wing, measured in exposed-wing root chords	4.3.2.2
$\frac{X_{c.p.}}{C_{c.p.}}$	empirically derived chordwise center-of-pressure location of the incremental load due to surface deflection	6.1.5.1
$\left(\frac{X_{c.p.}}{C_{c.p.}}\right)_1$	empirically derived factor of $\frac{X_{c.p.}}{C_{c.p.}}$	6.1.5.1
$\frac{X_{c.p.}}{C_r}$	distance of wing center-of-pressure location, in wing root chords, measured positive aft of wing apex	4.1.4.3
$\left(\frac{X_{c.p.}}{C_r}\right)_{C_L=0}$	wing center-of-pressure location at zero lift	4.1.4.3
$\left(\frac{X_{c.p.}}{C_r}\right)_{C_{L_{max}}}$	wing center-of-pressure location at maximum lift	4.1.4.3
$\left(\frac{X_{c.p.}}{C_r}\right)_{ref}$	wing reference center-of-pressure location	4.1.4.3
$\left(\frac{X_{c.p.}}{C_r}\right)_1$	component of wing center-of-pressure location at maximum lift due to leading-edge sharpness	4.1.4.3
$\Delta\left(\frac{X_{c.p.}}{C_r}\right)_2$, $\Delta\left(\frac{X_{c.p.}}{C_r}\right)_3$, $\Delta\left(\frac{X_{c.p.}}{C_r}\right)_4$	increments of wing center-of-pressure location due to planform geometry	4.1.4.3

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{x_{3D}}{x_{2D}}\right)_i$	ratio of center-of-lift location of a finite-aspect-ratio wing to center-of-lift location of an infinite-aspect-ratio wing for the incremental load due to deflection of the i^{th} trailing-edge flap segment	6.1.5.1
$\left(\frac{x_{3D}}{x_{2D}}\right)_j$	ratio of center-of-lift location of a finite-aspect-ratio wing to center-of-lift location of an infinite-aspect-ratio wing for the incremental load due to jet momentum acting at some angle to trailing-edge camber line	6.1.5.1
$\left(\frac{x_h}{c}\right)'$	distance of the hinge axis behind wing leading edge measured in plane normal to control hinge axis	6.1.6.1 6.1.6.2
Y_{90}, Y_{99}	airfoil ordinates at 90- and 99-percent chord, in percent chords	4.1.1.2 6.1.5.1 7.1.2.2
Y_{90}, Y_{100}	upper-surface ordinates of flap in retracted position at 90- and 100-percent chord, respectively, in fractions of the chord	6.1.1.1
y	1. airfoil ordinate at some value of x	2.2.1
	2. coordinate with origin at midspan of wing leading edge, perpendicular to plane of symmetry	4.4.1
	3. lateral coordinate measured positive to right of plane of symmetry	Several
Δy	1. difference between airfoil ordinate at 6% chord and ordinate at 0.15% chord	Several
	2. lateral distance from thrust axis of one propeller to blade element of another	9.1 9.1.3
	3. spanwise distance on constructed inboard panel = 1/2 b_i	4.1.4.2 4.3.2.2
y (x)	thickness distribution of airfoil	2.2.1
$\bar{y}$	lateral distance from axes origin to c.g. of component	8.2
y_B	spanwise location of break span station	2.2.2
$\bar{y}_H$	1. lateral center-of-pressure coordinate of the horizontal tail, measured from and normal to the longitudinal axis	6.2.1.2
	2. lateral centroidal distance of half horizontal stabilizer from aircraft plane of symmetry	8.1

SYMBOL	DEFINITION	SECTIONS
y_{MAC}	distance of the wing MAC from the plane of symmetry	2.2.2
y_T	spanwise distance from thrust axis to body center line	4.6 4.6.1
$\overline{y}_W$	lateral centroidal distance of half-wing from aircraft plane of symmetry	8.1
$y_{\overline{c}}$	lateral distance to wing mean aerodynamic chord from fuselage center line	6.1.4.2 6.1.5.1
$y'_{\overline{c}}$	lateral distance to mean aerodynamic chord of wing segment affected by the leading-edge device from fuselage center line	6.1.5.1
$y_c(x)$	camber-line distribution of airfoil	2.2.1
$(y_c)_{max}$	maximum ordinate of mean line of airfoil	2.2.1 4.3.2.1 4.3.3.2
y_i	spanwise distance from center line to inboard edge of flap or control surface	6.1.6.1 6.1.6.2 6.2.1.1 6.2.2.1
$y_{i,o}$	distance of inboard corners of horseshoe vortices from plane of symmetry	4.4.1
y_{max}	vertical distance from airfoil chord line to airfoil maximum upper-surface ordinate (see Sketch (a), Section 4.1.4.3)	4.1.4.3
y_o	1. distance of theoretical lateral vortex from plane of symmetry	Several
	2. spanwise distance from center line to outboard edge of flap or control surface	6.1.6.1 6.1.6.2 6.2.1.1 6.2.2.1
y_o, z_o	coordinate axes with origin at c.g. of component	8.2
$\frac{y_{v_1}}{b_V}, \frac{y_{v_2}}{b_V}$	body vortex lateral position at the vertical tail spans (defined by Equation 5.3.1.2-f)	5.3.1.2 5.6.1.2
$\Delta y_\perp$	value of Δy for chord perpendicular to wing leading edge, where Δy is defined above in 1.	Several

SYMBOL	DEFINITION	SECTIONS
Z	parameter used in determining horizontal stabilizer lift coefficient; defined by Equation 4.5.3.2-h	4.5.3.2
z	1. vertical distance between c.g. and quarter-chord point of wing MAC positive for MAC below c.g.	7.1.3.2
	2. vertical distance between c.g. and quarter-chord point of wing root chord, positive for quarter-chord point of root chord below c.g.	7.1.2.1 7.1.2.2 7.3.2.1 7.3.2.2
	3. vertical coordinate with origin at midspan of wing leading edge	4.4.1 4.5.1.1 4.5.1.2
	4. vertical distance from the vortex sheet to the point of interest (usually the quarter-chord point of the MAC of the horizontal tail)	4.4.1 7.4.1.1 7.4.4.1
	5. vertical distance of vertical-tail center-of-pressure location above or below moment-reference-center location	7.4.2.1 7.4.2.2 7.4.2.3
Δz	vertical distance between desired moment-reference-center-chord location and quarter-chord of MAC, positive for wing below desired location	6.1.5.1
z'	vertical distance of the horizontal tail below the body center line	6.2.1.2
z', z''	vertical distance between c.g. and quarter-chord point of forward and aft panel MAC's, respectively	4.5.2.1
$\bar{z}$	vertical distance from axes origin to c.g. of component	8.2
z_H	1. vertical distance between quarter-chord point of horizontal tail and X-axis, positive for tail below X-axis	Several
	2. distance measured normal to the longitudinal axis between the horizontal tail c.p. and the moment reference center, positive for c.p. above longitudinal axis	Several
	3. distance to c.p. of horizontal-tail-interference side force, measured from and normal to the longitudinal axis	5.3.3.2 5.6.3.2
	4. distance from quarter-chord point of wing MAC to quarter-chord point of horizontal-tail MAC, measured normal to longitudinal axis, positive for tail above wing	4.5.1.3
$z_{H_{eff}}$	vertical distance of center line of propeller slipstream from quarter-chord point of horizontal tail MAC (see Figure 4.6-13a), positive for slipstream above horizontal tail	4.6 4.6.3
z_{HL}	distance of hinge line measured from and normal to the X-axis, positive down	6.3.1
z_{H_T}	vertical distance from quarter-chord point of horizontal tail to propeller thrust axis; positive for quarter-chord point above thrust axis (see Figure 4.6-13a)	4.6 4.6.3
z_T	vertical distance from propeller thrust axis to coordinate origin, positive for thrust axis below origin (see Figure 4.6-13)	4.6 4.6.1 4.6.3
z_U	distance normal to the longitudinal axis between the lower-vertical-stabilizer (ventral) center of pressure and the moment reference center (normally negative)	5.3.3.2 5.6.2.1 5.6.3.2

SYMBOL	DEFINITION	SECTIONS
z_V	1. distance normal to the longitudinal axis between the upper-vertical-stabilizer center of pressure and the moment reference center (always positive)	Several
	2. vertical centroidal distance of vertical stabilizer from root chord (at fuselage)	8.1
z_W	1. vertical distance from the quarter-chord point of the wing MAC, to the coordinate origin, positive for wing below the origin (see Figure 4.6-13)	Several
	2. vertical distance from body center line to quarter-chord point of root chord, positive for quarter-chord point below center line	Several
	3. half-width of the wake at any position x	4.4.1 4.5.1.1 4.5.1.2 7.4.1.1
$z_{c.g.}$	vertical distance between c.g. and X-axis, positive for c.g. below X-axis	4.5.2.1 4.6
$\Delta z_{c.g.}$	vertical distance between c.g. and wing MAC quarter-chord, positive above quarter-chord	6.1.5.1
$(z_{c.p.})_{\Delta C_A}$	distance of center of pressure of axial-force increment from moment reference point, positive down	6.3.1
z_j'	distance from jet thrust axis to quarter-chord point of horizontal tail perpendicular to thrust axis, positive for quarter-chord point above thrust axis	4.6 4.6.1
z_o	vertical distance of theoretical vortex above reference plane	Several
z_p	distance normal to the longitudinal axis between the center of pressure of a vertical panel and the moment reference center, positive for the panel above the body	5.6.2.1
z_s	vertical distance from X-axis to propeller-slipstream center line at the quarter-chord of the wing MAC, positive for center line above X-axis (see Figure 4.6-13a)	4.6 4.6.1 4.6.3
$\left(\frac{2z}{b}\right)_{eff}$	effective value of height parameter relative to the displaced vortex	4.4.1
$\left(\frac{2z}{b'}\right)_{eff}$	value of parameter for forward panel	7.4.4.1
$\frac{z_H}{r_l}$	ratio of height of horizontal tail to average half-depth of body in region of horizontal tail (ratio is positive for tail below body center line)	5.3.1.1 5.6.1.1
$\frac{z_{v_1}}{b_V}, \frac{z_{v_2}}{b_V}$	body vortex vertical positions at the vertical tail spans; defined by Equation 5.3.1.2-f	5.3.1.2 5.6.1.2

B. GREEK SYMBOLS

SYMBOL	DEFINITION	SECTIONS
α	1. angle of attack, positive nose up	Several
	2. angular acceleration	8.1
	3. flow deflection angle	6.3.1
$\Delta\alpha$	1. angle-of-attack increment from incipient shock detachment to full detachment, $\alpha' - \alpha^*$	4.1.3.3
	2. change in wing angle of attack due to propeller upwash or downwash, $\frac{-\epsilon_p}{1+\frac{\partial \epsilon_u}{\partial \alpha}}$	4.6.1
	3. increment in angle of attack	4.7 4.7.1
α'	1. angle of attack at end of shock-detachment transition region	4.1.3.3
	2. angle of attack of forward panel	Several
	3. angle of inclination, $\sqrt{\alpha^2+\beta^2}$	Several
	4. an incidence angle defined as $\alpha' = \alpha$ for $0 \leq \alpha \leq 90^o$, and $\alpha' = 180^o - \alpha$ for $90^o \leq \alpha \leq 180^o$	4.2.1.2 4.2.2.2 4.2.3.2
α''	angle of attack of aft panel, $\alpha - \epsilon + i''$	4.1.5.2 4.5.1.2 4.5.2.1
$\overline{\alpha}$	transonic similarity parameter, $\frac{\alpha}{t/c}$	4.1.4.2
α^*	1. angle of attack at which section lift curve begins to deviate from linear variation	Several
	2. angle of attack at incipient shock detachment	4.1.3.3
$\alpha_{C_{L_{max}}}$	wing angle of attack at maximum lift coefficient	Several
$\Delta\alpha_{C_{L_{max}}}$	incremental value of parameter (see Figures 4.1.3.4-21b, -25b)	4.1.3.4
$\alpha'_{C_{L_{max}}}$	wing angle of attack of forward panel at maximum lift coefficient	7.4.4.1
$\left(\alpha_{C_{L_{max}}}\right)_{base}$	base value of parameter	4.1.3.3 4.1.3.4
$\left[\left(\alpha_{C_{L_{max}}}\right)_{base}\right]''_e$	subsonic angle of attack for $C_{L_{max}}$ of exposed aft panel	4.5.1.2

SYMBOL	DEFINITION	SECTIONS
$\left(\alpha_{C_{L_{max}}}\right)_e'$, $\left(\alpha_{C_{L_{max}}}\right)_e''$	angles of attack at maximum lift coefficients of exposed forward and aft panels, respectively	4.1.5.2
$\left(\Delta\alpha_{C_{L_{max}}}\right)_e'$	incremental value of parameter for exposed forward panel	4.5.1.2
$\left(\alpha_{C_{L_{max}}}\right)_W$	value of parameter for wing	4.3.1.4
$\left(\alpha_{C_{L_{max}}}\right)_{WB}$	value of parameter for wing-body combination	4.3.1.4 4.5.1.3
α_D	angle of attack between duct axis and free-stream direction	9.3 9.3.1 9.3.2 9.3.3
α_{FRP}	angle of attack for fuselage reference plane	4.3.1.3
$(\Delta\alpha)_G$	increment in angle of attack at a constant lift coefficient in the presence of the ground	4.7 4.7.1
α_H	angle of attack of horizontal tail or canard surface	4.6.3 4.7.1 6.3.4
$(\Delta\alpha_H)_G$	increment in angle of attack of the horizontal tail in the presence of the ground	4.7 4.7.1
α_L	local angle of attack for a particular spanwise wing section	6.1.5.1
α_T	angle of attack of thrust axis	4.6 4.6.1 4.6.3 4.6.4
α_V	angle of attack of vertical tail	6.3.4
α_W	angle of attack of wing	Several
$\Delta\alpha_W$	change in wing angle of attack ahead or behind the propellers	4.6.1
α_{WB}	wing-body angle of attack	4.5.3.2
α_{break}	angle of attack of wing at which the lift-curve slope becomes nonlinear	4.1.3.3
$\alpha_{c_\ell}{}_{max}$	section angle of attack at maximum lift coefficient	4.1.1 4.1.3.4 4.1.4.3 6.1.1
α_e	equivalent angle of attack for cambered wing	4.1.3.3
$(\alpha_e)_{C_{L_{max}}}$	equivalent angle of attack for cambered wing at maximum lift coefficient	4.1.3.3
α_i	angle of attack for section design lift coefficient	Several
α_{in}	inflow angle at propeller disk	9.1 9.1.3

SYMBOL	DEFINITION	SECTIONS
α_i	angle between jet thrust axis and local velocity at jet intake, $\alpha_T + \epsilon_u$	4.6 4.6.1 4.6.3
α_p	angle between propeller thrust axis and local velocity of propeller plane	4.6 4.6.1 4.6.4
α_s	angle of attack of surface to which main control surface is attached	6.3.4
$\Delta\alpha'_s$	change in section zero-lift angle of attack due to plug-type spoiler	6.1.1.1 6.2.1.1
α_v	angle of attack where onset of vortex lift begins	4.2.1.2
α_δ	control- or flap-effectiveness derivative, $-\frac{\partial \alpha}{\partial \delta}$	Several
$(\alpha_\delta)_{C_L}$	value of α_δ for a wing	6.1.4.1 6.1.5.1 6.1.7
$(\alpha_\delta)_{c_\ell}$	value of α_δ for an airfoil section	6.1.4.1 6.1.5.1 6.1.7
α_0	angle of attack at zero lift	Several
$\Delta\alpha_0$	change in wing zero-lift angle of attack due to linear wing twist	4.1.3.1
$(\alpha_0)_B$	body zero-lift angle of attack	4.3.2.1
$(\alpha_0)_W$	wing zero-lift angle of attack	4.3.2.1
$(\alpha_0)_{WB}$	wing-body zero-lift angle of attack	4.3.2.1
$(\alpha_0)_{\theta=0}$	angle of attack for zero lift of untwisted, constant-section wing	4.1.3.1 4.1.4.3
α_∞	free-stream angle of attack	6.3.2
$\alpha_\perp$	effective angle of attack perpendicular to the wing leading edge, $\tan^{-1}\frac{\tan\alpha}{\cos\Lambda_{LE}}$	4.1.3.1 4.1.3.3
$\frac{d\alpha_{in}}{d\alpha}$	propeller inflow angle of attack gradient	9.1.3
$\dot{\alpha}$	rate of change of angle of attack	7.4.4.1 7.4 4.2
β	1. Mach number parameter, $\sqrt{M^2-1}$ or $\sqrt{1-M^2}$	Several
	2. propeller blade angle at .75 R blade station	Several
	3. angle of sideslip, positive nose left	Several
	4. boattail angle	4.6.4
	5. control-tab gear ratio	6.3.4

SYMBOL	DEFINITION	SECTIONS
$\frac{\beta C_{l_\beta}}{\kappa\Gamma}$	(listed under C_{l_β})	
Γ	dihedral angle, positive wing tips up	Several
Γ', Γ''	dihedral angles of forward and aft surfaces, respectively, positive for wing tips up	4.5.1.1 7.4.1.1
Γ_y	value of circulation at any spanwise station	4.4.1
Γ_o	circulation at zero spanwise station	4.4.1
$\frac{\Gamma}{2\pi\, V r\alpha}$	nondimensional vortex strength	4.3.1.3 4.3.1.4 4.5.1.2 6.2.1.2
$\frac{\Gamma}{2\pi\, \alpha' V r}$	nondimensional vortex strength from Figure 4.3.1.3-15 with α replaced by α'	5.3.1.2 5.6.1.2
$\left[\frac{\Gamma_B}{2\pi\, V r\alpha}\right]'$, $\left[\frac{\Gamma_B}{2\pi\, V r\alpha}\right]''$	nondimensional vortex strengths for the forward and aft panels, respectively	4.5.1.2
$\frac{\Gamma_{yi}}{V\alpha\, b/2}$	circulation strength at $y_{i,o}$	4.4.1
$\frac{\Gamma_{yi+1} - \Gamma_{yi-1}}{V\alpha\, b/2}$	incremental circulation strength	4.4.1
γ	1. ratio of specific heats	Several
	2. angle with origin at wing trailing edge, measured between the zero-angle-of-attack line and the point under consideration	4.4.1 7.4.1.1
	3. dihedral angle of tail	4.5.1.1
	4. jet spreading angle (see Sketch (i), Section 6.1.5.1)	6.1.5.1
Δ_r	ratio of maximum deflections of control tab to main control surface	6.3.4
δ	1. semiwedge nose angle of sharp airfoils or cones	4.1.3.2 4.4.1 6.3.2
	2. flap or control deflection angle (also δ_f), elevators and flaps, positive trailing edge down; ailerons, positive such as to give positive rolling moment; rudder, positive trailing edge left	Several
	3. local slope of the surface of the vertical panel	5.3.1.1
	4. boundary-layer thickness	6.3.1
δ'	1. slope of airfoil surface with respect to free-stream velocity	4.4.1 5.3.1.2 5.6.1.2
	2. flap deflection in plane normal to constant-percent-chord line through $x_{c.p._h}$	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
δ_L	deflection of left-hand control surface	6.2.1.1 6.2.2.1
δ_{LE}	slope of airfoil surface at leading edge	4.4.1
δ_R	deflection of right-hand control surface	6.2.1.1 6.2.2.1
δ_{a_L} or δ_{a_R}	deflection of left or right aileron	6.2.2.1
δ_c	deflection of main control surface	6.3.4
$\delta_{c_{max}}$	maximum deflection of main control surface	6.3.4
δ_d	distance of deflector lip below lower surface of airfoil	6.2.1.1 6.2.2.1
δ_e	1. elevator deflection	6.3.4
	2. equivalent flap deflection due to wing camber and incidence	9.2 9.2.1 9.2.3
$\delta_{e_{max}}$	maximum elevator deflection	6.3.4
δ_{eff}	effective nose wedge angle for sharp-nosed airfoil (see Figure 4.1.3.3-61b)	4.1.3.3
$\delta_{eff_\perp}$	effective nose semiwedge angle for sharp-leading-edge wing, perpendicular to leading edge (see Figure 4.1.3.3-61b)	4.1.3.3
δ_f	1. deflection of flap or control surface (see δ)	Several
	2. force phase angle	9.1 9.1.3
δ_{f_i}	deflection of the i^{th} segment of trailing-edge flap	6.1.2.1 6.1.5.1
$\delta_{f_{LE}}$	deflection of leading-edge device	6.1.2.1
$\delta_{f_1}, \delta_{f_2}$	deflections of forward and aft flaps, respectively, (see Figures 6.1.1.1-45, -46)	Several
$\delta_{f_1}, \delta_{f_2}, \delta_{f_3}$	deflection of first, second, and third segments, respectively, of trailing-edge flaps (see Sketch (f), Section 6.1.2.1)	6.1.2.1
$\delta_{f_{\perp LE}}$	deflection of leading-edge flap, measured perpendicular to airfoil leading edge	6.1.5.1
δ_{i_f}	net turning angle of internal flow including power effects	9.3 9.3.1 9.3.2 9.3.3
δ_{i_o}	turning angle of internal flow with power off	9.3 9.3.1
δ_j	trailing-edge jet momentum angle, with respect to trailing-edge camber line	Several
$\delta_{j_{eff}}$	effective jet deflection angle with respect to airfoil chord	Several
δ_ℓ	deflection of aft flap segment, measured between trailing edge of lower surface of flap segment and line parallel to wing chord	6.1.2.1 6.1.4.1 6.1.4.2 6.1.4.3
δ_{max}	maximum plain-flap deflection for linear aerodynamic characteristics	6.1.3

SYMBOL	DEFINITION	SECTIONS
δ_n	slope of airfoil surface with respect to chord plane	4.4.1
δ_o	boundary-layer thickness at point where interaction begins	6.3.1
δ_s	height of spoiler lip above upper surface of airfoil	6.2.1.1 6.2.2.1
δ_{tc}	deflection of control tab	6.3.4
$\delta_{tc_{max}}$	maximum deflection of control tab	6.3.4
δ_{tt}	deflection of trim tab	6.3.4
δ_u	deflection of primary flap segment, measured between trailing edge of upper surface of flap segment and line parallel to wing chord	6.1.2.1 6.1.4.1 6.1.4.2 6.1.4.3
δ_{vn}	parameter in span-loading calculation	6.1.7
$\delta_\perp$	semiwedge angle measured perpendicular to wing leading edge	Several
$\delta_{\perp HL}$	control deflection measured perpendicular to hinge line	6.1.5.1 6.2.1.1
ϵ	downwash angle in plane of symmetry	Several
$\Delta\epsilon$	1. downwash increment due to flaps 2. downwash increment due to subsonic jet in a subsonic stream	4.4.1 4.6 4.6.1
$\bar{\epsilon}$	1. average downwash over aft surface	4.4.1 6.2.1.2
	2. effective downwash over the wing span	4.6 4.6.4
$\Delta\bar{\epsilon}$	mean-effective-downwash increment	4.6 4.6.1
$(\Delta\epsilon)_G$	increment in downwash due to ground effect in the linear-lift range	4.7 4.7.1
ϵ_H	average downwash angle at the tail	4.4.1 4.5.3.2 4.6.3
$(\Delta\epsilon)_H$	increment in downwash at the tail	4.6.3
ϵ_p	downwash due to propeller power effects	4.6 4.6.1 4.6.3 4.6.4
$\epsilon_{power\ off}$	power-off downwash angle	4.6.3
ϵ_u	upwash angle ahead of the wing	4.6 4.6.1 4.6.3
ϵ_v	downwash at plane of symmetry at height of vortex core	4.4.1
$\epsilon_{z_{slip}}$	upwash induced by propeller slipstream, positive down	9.1 9.1.3

SYMBOL	DEFINITION	SECTIONS
η	1. dimensionless span station, $\frac{y}{b/2}$	Several
	2. ratio of the drag on a finite cylinder to the drag of a cylinder of infinite length	4.2.1.2 4.2.2.2 4.2.3.2 4.3.3.2
	3. angle of sweep of the line intersecting conical-flow regions of wing at angle of attack	6.1.6.1
	4. dimensionless span station, $\cos \frac{v\pi}{m+1}$, $\cos \frac{n\pi}{m+1}$	6.1.7
	5. control-surface efficiency	6.3.4
$\Delta\eta$	increment in dimensionless lateral direction, $\frac{\Delta y}{b/2}$	6.1.4.1 6.1.5.1
$\overline{\eta}$	lateral distance of wing MAC from body center line in semispans	6.1.5.1
η_B	1. dimensionless distance from plane of symmetry to break span station	Several
	2. Mach-number correction to the interference force	5.2.1.2 5.3.1.2
η_W	tail-effectiveness parameter	5.6.1.2
$\eta_{W(U)}$	lower-vertical-stabilizer effectiveness factor	5.6.1.2
$\eta_{W(V)}$	upper-vertical-stabilizer effectiveness factor	5.6.1.2
$\eta'_{\bar{c}}$	dimensionless span station of mean aerodynamic chord of wing segment affected by leading-edge device	6.1.5.1
$\eta_{c.p.}$	spanwise location of the center of pressure of the exposed horizontal tail	6.2.1.2
η_f	dimensionless distance from plane of symmetry to edge of flap or control surface, $\frac{y}{b/2}$	6.1.5.1
η_i	dimensionless distance from plane of symmetry to inboard edge of flap or control surface, $\frac{y_i}{b/2}$	Several
$\Delta\eta_i, \Delta\eta_o$	effective increments in spoiler spanwise inboard and outboard locations, respectively, due to spanwise flow of spoiler wake for partial-span spoilers	6.2.1.1
$\eta_{i_{eff}}, \eta_{o_{eff}}$	effective locations of inboard and outboard ends, respectively, of spoilers	6.2.1.1
η_k, η_{k-1}	dimensionless span stations denoting outboard and inboard ends, respectively, of the kth wing section	6.1.5.1
η_{max}	empirical factor accounting for maximum lifting efficiency	6.1.1.3
η_o	dimensionless distance from plane of symmetry to outboard edge of flap or control surface, $\frac{y_o}{b/2}$	Several
η_t	1. turning-efficiency factor of the aft flap segment	6.1.1.1
	2. static turning efficiency defined as resultant force divided by gross thrust	6.1.4.3 6.1.5.1

SYMBOL	DEFINITION	SECTIONS
η_α	lumped parameter containing the effects of downwash, dynamic-pressure ratio, and Mach number	4.5.1.2
η_δ	empirical factor accounting for changes in flap deflection from the optimum deflection	6.1.1.3
$\eta_0, \eta_1, \eta_2, \eta_3$	dimensionless span stations, from center line outboard on wing	6.1.5.1
η_1	empirical lift-efficiency factor of a single-slotted flap, a vane, or forward-flap segment of double-slotted flap	6.1.1.1
η_2	empirical lift-efficiency factor of the aft-flap segment of a double-slotted flap	6.1.1.1
$\eta\left(\frac{q_H}{q}\right)$	tail-effectiveness factor for configurations with body-mounted horizontal tails	6.2.1.2
θ	1. slope of airfoil mean line at leading edge	2.2.1
	2. linear angle of twist of wing tip with respect to root, negative for washout	Several
	3. ratio of ambient static temperature to jet-exit static temperature	4.6.1
	4. surface slope of cone frustum	Several
	5. shock-wave angle	4.4.1 6.3.1
	6. leading-edge shock angle	5.3.1.2 5.6.1.2
	7. angular pitching velocity	7.1.1.2
	8. slipstream turning angle measured from thrust axis	9.2 9.2.1 9.2.3
	9. spoiler deflection angle	6.2.1.1
	10. body surface slope	4.2.1.2 4.2.2.2
	11. angle of conical divergence	4.6.4
	12. angle of secondary shock	6.3.2
$\Delta\theta$	increment of slipstream turning angle due to wing camber and incidence	9.2 9.2.1
$\tilde{\theta}$	angle between airfoil chord line and line connecting airfoil trailing edge with maximum airfoil upper-surface ordinate (see Sketch (a), Section 4.1.4.3)	4.1.4.3
θ_F	surface slope of flared afterbody	4.2.1.1 4.2.1.2 4.2.2.1
θ_N	1. surface slope of conical body section having a blunted nose	4.2.1.2
	2. surface slope of nose	4.2.3.1 4.3.3.1 5.3.3.1
θ_c	cone angle	4.2.2.1

SYMBOL	DEFINITION	SECTIONS
θ_f	slipstream turning angle adjusted to the condition of zero camber and zero incidence	9.2 9.2.1
θ_1	trailing-edge shock angle	5.3.1.2 5.6.1.2
$\theta_1, \theta_2, \theta_3, \ldots$	local surface slope of body segments	4.2.2.1
κ	ratio of two-dimensional lift-curve slope at appropriate Mach number to $2\pi/\beta$; or, ratio of incompressible two-dimensional lift-curve slope to 2π	Several
Λ_{HL}	sweepback angle of hinge line of flap or control surface	Several
$\Lambda_{H_{c/4}}$	sweep angle of horizontal-tail quarter-chord	4.6 4.6.3
$\Lambda_{LE}, \Lambda_{LE_W}, \Lambda$	sweepback angle of wing leading edge	Several
$\Lambda'_{LE}, \Lambda''_{LE}$	sweepback angles of leading edges of forward and aft surfaces, respectively	4.5.1.1 4.5.1.2 /.4.1.1
$\Lambda_{LE_{bw}}$	sweepback angle of leading edge of basic wing	4.1.3.2 4.1.5.1 4.3.3.1 5.1.2.1
Λ_{LE_e}	sweepback angle of leading edge of exposed wing	4.3.2.2
$(\Lambda_{LE_e})_i$	sweepback angle of leading edge of inboard panel of exposed wing	4.3.2.2
Λ_{LE_g}	sweepback angle of leading edge of glove of double-delta and cranked wings	4.1.3.2 5.1.2.1
Λ_{LE_H}	sweepback angle of horizontal-stabilizer leading edge	4.5.3.1 8.1
$\Lambda_{LE_i}, \Lambda_{LE_o}$	sweepback angles of leading edge of wing inboard and outboard panels, respectively	Several
Λ'_{LE_o}	sweepback angle of leading edge of constructed outboard panels of wing	4.1.4.2 4.3.2.2
Λ_{LE_U}	sweepback angle of lower-vertical-stabilizer leading edge	Several
Λ_{LE_V}	sweepback angle of upper-vertical-stabilizer leading edge	Several
$\Lambda_{LE_1}, \Lambda_{LE_2}$	sweepback angles of leading edge of constructed panels of non-straight-tapered wings	4.1.3.2
Λ_{TE}	sweepback angle of wing trailing edge	Several
$\Lambda_{TE_{bw}}$	sweepback angle of trailing edge of basic wing	4.1.3.2 4.1.5.1 4.3.3.1
Λ_{TE_E}	sweepback angle of trailing edge of extension of double-delta and cranked wings	4.1.3.2

SYMBOL	DEFINITION	SECTIONS
$\Lambda_{TE_i}, \Lambda_{TE_o}$	sweepback angles of trailing edge of wing inboard and outboard panels, respectively	4.1.3.2 4.1.4.2 4.1.5.1
Λ_b	sweepback of constant-percent-chord line through center of pressure of basic loading (see Equation 6.1.5.1-g)	6.1.5.1
Λ_c	complement of leading-edge sweep angle; $\Lambda_c = 90^0 - \Lambda_{LE}$	4.1.3.2 4.1.4.1
$\Lambda_{c/(\ )}$	sweepback angle of a constant-percent-chord line	Several
$\Lambda_{c/2}, \Lambda_{c/2_W}$	sweepback angle of wing 50-percent-chord line	Several
$\Lambda'_{c/2}, \Lambda''_{c/2}$	sweepback angles of 50-percent-chord line of forward and aft surfaces, respectively	4.5.1.1 7.4.1.1
$\Lambda_{3c/4}$	sweepback angle of the three-quarter-chord point of the wing	4.4.1
$\Lambda_{c/2_e}$	sweepback angle of midchord line of exposed wing	4.3.2.2
$\Lambda_{c/2_{eff}}$	effective sweepback angle of midchord line of exposed wing	4.1.3.2 4.1.3.3
$\Lambda_{c/2_i}, \Lambda_{c/2_o}$	sweepback angles of midchord line of wing inboard and outboard panels, respectively	4.1.3.2 4.1.3.3 4.1.4.2 5.1.2.1
$\Lambda_{c/2_j}$	sweepback angle of midchord line of one section of n sections	4.1.3.2 4.1.3.3
$\Lambda'_{c/2_o}$	sweepback angle of midchord line of constructed outboard panel of wing	5.1.2.1
$\Lambda_{c/2_U}$	sweepback angle of the midchord line of the lower vertical stabilizer	5.3.1.1 5.6.1.1
$\Lambda_{c/2_V}$	sweepback angle of the midchord line of the upper vertical stabilizer	5.3.1.1
$\Lambda_{c/4_W}, \Lambda_{c/4}$	sweepback angle of the quarter-chord line of the wing	Several
$\Lambda'_{c/4}, \Lambda''_{c/4}$	sweepback angles of quarter-chord line of forward and aft surfaces, respectively	4.5.1.1 7.4.4.1
Λ_m, Λ_n	sweepback angles of arbitrary chordwise locations	2.2.2
Λ_s	sweepback angle of spoiler hinge line	6.2.1.1
$\Lambda_{(t/c)_{max}}$	sweepback angle of airfoil maximum-thickness line of wing	4.1.5.1 4.3.3.1 4.5.3.1
$\Lambda_{(t/c)_{max_i}}$, $\Lambda_{(t/c)_{max_o}}$	sweepback angles of airfoil maximum-thickness line of wing inboard and outboard panels, respectively	4.1.5.1 4.3.3.1

SYMBOL	DEFINITION	SECTIONS
Λ_β	compressible sweep parameter, $\tan^{-1}\left(\frac{\tan \Lambda_{c/4}}{\beta}\right)$	Several
λ	1. taper ratio, $\frac{\text{tip chord}}{\text{root chord}}$	Several
	2. mean free path (average distance traveled between molecular collisions)	6.3.2
λ', λ''	taper ratios of forward and aft surfaces, respectively	4.5.1.1 7.4.1.1 7.4.4.1
λ_H	taper ratio of horizontal tail or canard surface	Several
λ_{H_e}	taper ratio of exposed horizontal tail	6.2.1.2
λ_U	taper ratio of lower vertical stabilizer, measured from fuselage center line	Several
λ_{U_e}	taper ratio of exposed lower vertical stabilizer	Several
λ_V	taper ratio of upper vertical stabilizer, measured from fuselage center line	Several
λ_{V_e}	taper ratio of exposed upper vertical stabilizer	Several
λ_W	wing taper ratio	Several
λ_{bw}	taper ratio of basic wing	4.1.3.2 4.1.5.1 4.3.3.1 5.1.2.1
λ_e	taper ratio of exposed wing panel	Several
λ'_e, λ''_e	taper ratios of forward and aft exposed surfaces, respectively	4.4.1 4.5.1.1 7.4.1.1
$(\lambda_e)_i$ or $(\lambda_i)_e$	taper ratio of inboard panel of exposed wing	4.3.2.2 4.3.3.1
λ_f	taper ratio of flap or control surface	6.1.4.1 6.1.5.1
λ_g	taper ratio of glove of double-delta and cranked wings	4.1.3.2 5.1.2.1
λ_i, λ_o	taper ratios of wing inboard and outboard panels, respectively	Several
λ'_o	taper ratio of constructed outboard panel of wing	4.1.4.2 4.3.2.2 5.1.2.1
λ_1, λ_2	taper ratios of constructed panels of non-straight-tapered wings	4.1.3.2

SYMBOL	DEFINITION	SECTIONS
μ	Mach angle, $\sin^{-1}\frac{1}{M}$	Several
ν	Prandtl-Meyer angle	4.4.1 5.3.1.2 5.6.1.2
$\Delta\nu$	increment in flow angle between two points on the body surface	4.4.1
ξ	1. any station along body	4.3.3.1
	2. pressure ratio along secondary shock	6.3.2
ξ_{ru}	distance required for complete rollup of wing-tip vortices, measured parallel to the wing root chord from the tip quarter-chord point, in semispans	4.4.1 7.4.4.1
ρ	1. ratio of weight to chord for wing	8.1
	2. air density	4.6 6.3.2
ρ_P	pitch radius of gyration	8.2
ρ_R	roll radius of gyration	8.2
$\rho_{x_o}, \rho_{y_o}, \rho_{z_o}$	radii of gyration at the c.g. of the component	8.2
σ	1. geometric planform parameter, $\frac{A}{4}(1+\lambda)\tan\Lambda_{LE}$	2.2.2 4.1.3.2 4.1.4.3
	2. Prandtl interference coefficient	4.7 4.7.1 4.7.4
	3. sidewash, positive out the left wing	5.4.1
	4. boundary-layer separation angle	6.3.2
	5. air density ratio, ρ/ρ_o	6.3.4
	6. propeller solidity, ratio of blade element area to annular area at 0.75R	9.1 9.1.1 9.1.3
σ_e	effective propeller solidity	9.1 9.1.1 9.1.3
τ	1. one-half the thickness ratio of the forward-facing surface of a wedge airfoil	4.1.5.1
	2. angle denoting an arbitrary position of the ray in the conical-flow field	6.1.6.1
$\tau_{c.p.}$	angle of a ray in the conical-flow field which passes through the center of pressure	6.1.6.1
Φ	effective turning angle	6.1.1.1

SYMBOL	DEFINITION	SECTIONS
ϕ	1. angle of bank of elliptical-cross-section body about its longitudinal axis, measured from the major axis	4.2.1.2 4.2.2.2 4.2.3.2
	2. roll angle	4.3.3.1 6.1.7
	3. angle of inclination normal to body center line, $\tan^{-1}\frac{\beta}{\alpha}$	5.3.1.2 5.6.1.2
	4. angle associated with geometry of separation	6.3.1
	5. inclination of nozzle center line relative to an axis normal to surface	6.3.2
ϕ_{TE}	1. streamwise trailing-edge angle	Several
	2. trailing-edge angle measured normal to control hinge line	6.1.4.1 6.1.5.1 6.1.6.1 6.2.1.1
ϕ'_{TE}	trailing-edge angle based on airfoil ordinates at 90- and 99-percent chord	Several
ϕ''_{TE}	trailing-edge angle based on airfoil ordinates at 95- and 99-percent chord	6.1.3.1 6.1.3.2 6.1.6.1 6.1.6.2
$\phi_{TE_{upper}}$	$\tan^{-1}\frac{Y_{90} - Y_{100}}{0.10}$	6.1.1.1
ϕ_n	span-loading angle calculated at spanwise station n, $\frac{n\pi}{m+1}$	6.1.7
ϕ_v	span loading angle calculated at spanwise station v, $\frac{v\pi}{m+1}$	6.1.7
ϕ_β	lift-efficiency factor for a geared tab system, $1 + \beta C_2/C_1$	6.3.4
Ω	angle used in determination of trim drag (see Figure 4.5.3.2-4)	4.5.3.2

C. CAPITAL-LETTER COEFFICIENTS AND DERIVATIVES

SYMBOL	DEFINITION	SECTIONS
ΔC_A	increment in axial-force coefficient	6.3.1
C_D	drag coefficient, $\frac{\text{drag}}{qS}$	Several
$(C_D)'$	total drag coefficient of the forward panel and body, including wing-body interference	4.5.2.1
$(C_D)''$	total drag coefficient of the aft panel, including wing-body interferences	4.5.2.1
ΔC_D	zero-lift drag coefficient due to flap deflection based on free-stream velocity	9.2 9.2.3
$C_D(\alpha)$	drag due to angle of attack	4.2.3.2 4.3.3.2
$[C_D(\alpha)]_B$	body drag due to angle of attack	4.3.3.2
$[C_D(\alpha)]_{a/b}$	drag due to angle of attack of a body having an elliptical cross section	4.2.3.2
C_{D_A}	wave-drag coefficient based on maximum frontal area of afterbody	Several
ΔC_{D_A}	reduction in afterbody wave-drag coefficient of a body of revolution with elliptic cross section	4.2.3.1
$C_{D_{A(NC)}}$	coefficient of interference drag acting on the afterbody due to the nose and cylindrical section	4.2.3.1 4.2.3.2 4.3.3.1 4.5.3.1
C_{D_b}	base drag coefficient	Several
$(C_{D_b})_B$	base-pressure drag coefficient for the body	4.3.3.1
C_{D_e}	external duct drag coefficient, $\frac{-F_{x_e}}{q_\infty S_D}$	9.3 9.3.1
C_{D_f}	1. skin-friction drag coefficient	Several
	2. power-off zero-lift drag coefficient	9.2 9.2.3
$\Delta(C_{D_f})$	increment of skin-friction drag due to control-surface or flap deflection	6.1.7
$(C_{D_f})_B$	body skin-friction drag coefficient	4.2.3.1 4.3.3.1

SYMBOL	DEFINITION	SECTIONS
$\left(C_{D_f}\right)_b$	zero-lift drag of body exclusive of the base drag, based on body base area	4.2.3.1 4.2.3.2 4.3.3.1 4.5.3.1
$\left(C_{D_f}\right)_H$	compressible skin-friction drag coefficient of horizontal stabilizer, based on total horizontal stabilizer area	4.5.3.1
$\left(C_{D_f}\right)_V$	compressible skin-friction drag coefficient of vertical stabilizer, based on vertical stabilizer area to body center line	4.5.3.1
$\left(C_{D_f}\right)_W$	compressible skin-friction drag coefficient of wing, based on total wing area	4.3.3.1 4.5.3.1
C_{D_H}	drag coefficient of horizontal stabilizer, $\frac{\text{horizontal-tail drag}}{qS_H}$	4.5.3.2 4.6.2
$\left(C_{D_H}\right)_{\alpha_{C_{L_{max}}}}$	horizontal-tail-body drag at stall angle of attack	4.5.1.3
C_{D_i}	induced-drag coefficient	6.1.7
C_{D_L}	drag coefficient due to lift	Several
ΔC_{D_L}	increment in drag due to lift resulting from a breakdown in leading-edge suction at lift coefficients above parabolic-drag-polar region	4.1.5.2
$C_{D_{LE}}$	pressure-drag coefficient of a swept, cylindrical leading edge	4.1.5.1 4.3.3.1
$\left(\Delta C_{D_L}\right)_G$	change in drag due to lift caused by ground effect	4.7 4.7.4
$\left(C_{D_L}\right)_W$	drag due to lift of the wing, based on total wing area	4.3.3.2
$\left(C_{D_L}\right)_{WB}$	drag due to lift of a wing-body configuration	4.3.3.2
$(C_D)_{min}$	minimum drag coefficient	6.1.7
$\Delta C_{D_{min}}$	increment in minimum drag coefficient due to control-surface or flap deflection	6.1.7
$\left(C_{D_{min}}\right)_{flaps\ up}$ or $\left(C_{D_{min}}\right)_{\delta = 0}$	minimum drag coefficient for undeflected control or flap	6.1.7
$C_{D_{N_I}}$	wave-drag coefficient of spherically blunted noses	4.2.3.1 4.3.3.1 4.5.3.1

SYMBOL	DEFINITION	SECTIONS
$\Delta C_{D_{N_1}}$	reduction in forebody wave-drag coefficient of a body of revolution with an elliptic cross section	4.2.3.1
$C_{D_{N_2}}$	wave-drag coefficient of conical or ogive-profile nose, based on maximum frontal area of nose	4.2.3.1 4.3.3.1 4.5.3.1
C_{D_o}	power-off drag coefficient based on free-stream velocity and wing area, $\frac{\text{drag}}{q_\infty S}$	9.2 9.2.3
C_{D_p}	subsonic pressure-drag coefficient	4.2.3.1 4.3.3.1 4.5.3.1
$C_{D_{p_n}}$	pressure-drag coefficient of any of n segments of a body	4.2.3.1
$C_{D_{p_1}}, C_{D_{p_2}}, C_{D_{p_3}}, \ldots$	pressure-drag coefficient of given body segments	4.2.3.1
$\Delta C_{D_{Trim}}$	incremental drag coefficient of horizontal stabilizer including both zero-lift and induced drag	4.5.3.2
C_{D_v}	viscous drag coefficient due to lift	4.1.5.2
C_{D_w}	supersonic wave-drag coefficient of the body	Several
$C_{D_{wave}}$	wave-drag coefficient	6.1.7
$\Delta\left(C_{D_{wave}}\right)$	increment in wave-drag coefficient due to control deflection	6.1.7
$\left(C_{D_{wave}}\right)_{\delta = 0}$ or $\left(\Delta C_{D_0}\right)_{\delta = 0}$	zero-lift wave-drag increment at transonic speeds for undeflected control or flap	6.1.7
$\left(C_{D_w}\right)_B$	wave-drag coefficient of the body	4.3.3.1
$C_{D_{WB}}$	wing-body drag coefficient in absence of ground plane	4.7 4.7.4

SYMBOL	DEFINITION	SECTIONS
$(C_D)_{WB}$	drag coefficient of a wing-body combination at angle of attack	4.3.3.2
$(C_{D_{WB}})_G$	wing-body drag coefficient in the presence of the ground	4.7 4.7.4
$(C_{D_w})_H$	supersonic wave-drag coefficient of the horizontal-tail panel	4.5.3.1
$C_{D_{w_{peak}}}{}_{\Lambda_{c/4}=n}$	maximum wave-drag-coefficient increment for swept wing with $\Lambda_{c/4} = n$	4.1.5.1 4.3.3.1
$C_{D_{w_{peak}}}{}_{\Lambda_{c/4}=0}$	maximum wave-drag-coefficient increment for an unswept wing	4.1.5.1
$(C_{D_w})_V$	supersonic wave-drag coefficient of the vertical-tail panel	4.5.3.1
$(C_{D_w})_W$	supersonic wave-drag coefficient of the wing	4.3.3.1 4.5.3.1
$(C_{D_\alpha})'$	total drag-curve slope of the forward panel and body, including interferences	4.5.2.1
$(C_{D_\alpha})''$	total drag-curve slope of the aft panel and body, including interferences	4.5.2.1
$(C_D)_\delta$	drag coefficient for control surface or flap deflection	6.1.7
$(C_D)_{\delta=0}$	drag coefficient for zero control surface or flap deflection	6.1.7
C_{D_0}	1. zero-lift drag coefficient	Several
	2. profile-drag coefficient of the wing at any given lift coefficient	7.1.3.2 7.1.3.3 7.3.2.2
ΔC_{D_0}	increment of zero-lift wave-drag coefficient at transonic speeds	4.1.5.1 4.3.3.1 4.5.3.1
$(C_{D_0})_B$	total zero-lift drag coefficient of body	4.3.3.1 4.5.3.1
$(\Delta C_{D_0})_{flap}$	increment of zero-lift drag coefficient due to flap deflection	4.6.4
$(\Delta C_{D_0})_{\substack{flaps \\ power\ on}}$	increment of zero-lift drag coefficient for the flap extended and immersed in the propeller slipstream	4.6.4

SYMBOL	DEFINITION	SECTIONS
$(C_{D_0})_H$	zero-lift drag coefficient of horizontal stabilizer, based on total horizontal-stabilizer area	4.5.3.1 4.5.3.2
$(C_{D_0})_i, (C_{D_0})_o$	zero-lift drag coefficients of wing inboard and outboard panels, respectively	4.1.5.1 4.3.3.1
$(C_{D_0})_{\text{lifting surface}}$	zero-lift drag coefficient of lifting surface	4.5.3.1
$(C_{D_0})_{M_D}$	zero-lift drag coefficient at drag-divergence Mach number	4.5.3.1
$(C_{D_0})_{M_I}$	zero-lift drag coefficient at initial drag-rise Mach number	4.5.3.1
$(\Delta C_{D_0})_{\text{power on}}$	increment of zero-lift drag for propeller power	4.6.4
$(\Delta C_{D_0})_s$	increment of skin-friction zero-lift drag coefficient due to propeller slipstream	4.6.4
$(C_{D_0})_V$	zero-lift drag coefficient of vertical stabilizer, based on vertical-stabilizer area to body center line	4.5.3.1 4.5.3.2
$(C_{D_0})_W$	zero-lift drag coefficient of wing, based on total wing area	4.3.3.1 4.5.3.1
$(C_{D_0})_{WB}$	zero-lift drag coefficient of wing-body combination	4.3.3.1 4.3.3.2 4.5.3.1 4.5.3.2
$C_{D_1}, C_{D_2}, C_{D_3}, \cdots$	drag coefficients of various components of body	4.2.3.1
C_{F_c}	control-force coefficient	6.3.2
$(C_{F_c})_{cr}$	corrected control-force coefficient	6.3.2
C_{F_x}	1. negative-drag coefficient based on free-stream velocity and wing area, $\frac{F_x}{q_\infty S}$	9.2
	2. duct negative-drag coefficient based on free-stream velocity and duct planform area, $\frac{F_x}{q_\infty S_D}$	9.3 9.3.2 9.3.3

SYMBOL	DEFINITION	SECTIONS
C_{F_x}''	negative-drag coefficient based on slipstream velocity and wing area, $\frac{F_x}{q''S}$	9.2 9.2.3
$C_{F_{x_e}}$	external duct negative-drag coefficient based on free-stream velocity and duct planform area, $\frac{F_{x_e}}{q_\infty S_D}$	9.3 9.3.1 9.3.3
C_J	three-dimensional trailing-edge jet momentum coefficient for jet-flap configurations	6.1.4.1 6.1.4.2 6.1.4.3 6.1.5.1
C_J'	three-dimensional trailing-edge jet momentum coefficient, based on blown-flap affected area	6.1.4.1 6.1.4.2
C_L	1. lift coefficient, $\frac{\text{lift}}{qS}$	Several
	2. duct lift contribution, $\frac{\text{lift}}{q_\infty S_D}$	9.3 9.3.1 9.3.2
ΔC_L	1. increment in lift due to leading-edge vortex at particular angle of attack (see Sketch (b), Section 4.1.3.2)	4.1.3.2 4.1.4.3
	2. increment in lift beyond the lift coefficient at α_{break}	4.1.3.3
	3. increment of wing lift coefficient due to flap or control-surface deflection	6.1.4.1 6.1.5.1
$(C_L)'$	total lift coefficient of the forward panel and body, including wing-body interference	4.5.2.1 7.4.1.1
C_L''	lift coefficient based on slipstream velocity, $\frac{\text{lift}}{q''S}$	9.2 9.2.1
$(C_L)''$	total lift coefficient of the aft panel, including wing-body interferences	4.5.2.1
$(C_L)_{a/b}$	lift coefficient of a body with elliptical cross section	4.2.1.2
$C_{L_{basic}}$	basic wing lift coefficient excluding leading-edge vortex-induced effects	4.1.4.3
$C_{L_{break}}$	lift coefficient where lift curve becomes nonlinear	4.1.3.3
C_{L_c}	"critical" lift coefficient, where drag-due-to-lift factor is no longer a constant	4.1.5.2
ΔC_{L_c}	lift increment due to control surface	6.3.4
C_{L_d}	conical-camber design lift coefficient for a M = 1.0 design with the designated camber ray line intersecting the wing trailing edge at 0.3 b/2	4.3.2.1
C_{L_e}	lift coefficient resulting from external mass flow	9.3 9.3.1 9.3.2
$(C_L)_e'$	lift coefficient of the exposed forward panel	4.5.1.2

SYMBOL	DEFINITION	SECTIONS
ΔC_{L_f}	increment in wing lift coefficient due to symmetric flap deflection in absence of ground plane	4.7 4.7.1 6.1.7
$\left(C_{L_f}\right)_{WB}$	wing-body lift coefficient including flap effects in absence of ground plane	4.7.1
$\Delta\left(\Delta C_L\right)_{flap}$	empirical factor accounting for flap effects in the presence of the ground	4.7 4.7.1
$C_L(g)$	lift-coefficient correction term	7.1.4.1 7.3.4.1
$\left(\Delta C_L\right)_G$	increment in wing or horizontal tail lift due to the presence of the ground plane	4.7
C_{L_H}	lift coefficient of horizontal tail, $\frac{\text{horizontal-tail lift}}{qS_H}$	4.5.3.2 4.6.3 4.7.1 6.3.4
$\left(\Delta C_L\right)_H$	increment in lift coefficient due to horizontal tail	4.6 4.6.1
$\left(\Delta C_{L_H}\right)_G$	increment in horizontal-tail lift in the presence of the ground	4.7 4.7.3
$C_{L_{H(WBV)}}$	horizontal-tail-body lift in presence of the wing, body, and vertical tail	4.5.1.3
C_{L_i}	lift coefficient resulting from internal mass flow	9.3 9.3.1 9.3.2
$\left(C_{L_i}\right)_{WB}$	rate of change of lift coefficient with wing incidence (fuselage angle of attack held constant)	4.3.1.2
$C_{L_{max}}$	maximum lift coefficient, $\frac{\text{maximum lift}}{qS}$	Several
$\Delta C_{L_{max}}$	1. increment in wing maximum lift coefficient accounting for Mach-number effects	4.1.3.3 4.1.3.4
	2. increment in wing maximum lift coefficient due to propeller power	4.6 4.6.2
	3. increment in wing maximum lift coefficient due to flap deflection	6.1.4.3
$C_{L_{max}}^*$	maximum lift coefficient wing as determined by the low-aspect-ratio method	4.1.3.3
$\left(C_{L_{max}}\right)_{base}$	base value of parameter	4.1.3.3 4.1.3.4
$\left[\left(C_{L_{max}}\right)_{base}\right]_e''$	subsonic maximum lift coefficient of exposed aft panel	4.5.1.2
$\left(C_{L_{max}}\right)_e$	maximum lift coefficient for exposed wing	4.1.3.4

SYMBOL	DEFINITION	SECTIONS
$(C_{L_{max}})_e'$, $(C_{L_{max}})_e''$	maximum lift coefficients of exposed forward and aft panels, respectively	4.1.5.2
$(\Delta C_{L_{max}})_e'$, $(\Delta C_{L_{max}})_e''$	increments in wing maximum lift coefficients accounting for Mach number effects on the forward and aft panels, respectively	4.1.5.2
$(C_{L_{max}})_W$	value of parameter for wing	4.3.1.4
$(C_{L_{max}})_{WB}$	maximum lift coefficient for wing-body	4.3.1.4 4.5.1.3
$(\Delta C_L)_{N_j}$	increment in lift coefficient acting at jet-engine inlet due to inclination of thrust axis to oncoming flow	4.6 4.6.1 4.6.4
$(\Delta C_L)_{N_p}$	increment in lift coefficient due to inclination of propeller plane to oncoming flow	4.6 4.6.1 4.6.3
$C_{L_{nonlinear}}$	lift coefficient above point where the lift curve ceases to be linear	4.1.3.3
C_{L_o}	power-off lift coefficient based on free-stream velocity and wing area, $\frac{L}{q_\infty S}$	9.2 9.2.1 9.2.3
C_{L_p}	lift coefficient due to propeller effects	4.6 4.6.4
$(C_L)_{\substack{power \\ off}}$	lift coefficient of configuration, power off	4.6.1
$(\Delta C_L)_{\substack{power \\ on}}$	increment in lift coefficient due to propeller power	4.6.1 4.6.2
C_{L_q}	pitching derivative, $\frac{\partial C_L}{\partial\left(\frac{q\bar{c}}{2V_\infty}\right)}$	Several
$(\Delta C_L)_q$	increment in lift coefficient due to change in dynamic pressure behind propeller	4.6 4.6.1 4.6.3
C_{L_q}'	value of pitching derivative referred to body axes with origin at wing aerodynamic center	7.1.1.1 7.1.1.2 7.3.1.1
C_{L_q}''	value of pitching derivative referred to body axes with origin at wing leading-edge vertex	7.1.1.1 7.1.1.2
$(C_{L_q})_B$	contribution of the body to pitching derivative C_{L_q}	7.3.1.1 7.4.1.1

SYMBOL	DEFINITION	SECTIONS
$\left(C_{L_q}\right)_e$	contribution of the exposed wing to the pitching derivative C_{L_q}	7.3.1.1 7.3.1.2
$\left(C_{L_q}\right)'_e, \left(C_{L_q}\right)''_e$	contributions of exposed forward and aft panels, respectively, to the pitching derivative C_{L_q}	7.4.1.1
$\left(C_{L_q}\right)_W$	contribution of the wing to the pitching derivative C_{L_q}	7.3.1.1
$\left(C_{L_q}\right)_{WB}$	contribution of the wing-body combination to the pitching derivative C_{L_q}	7.3.1.1 7.4.1.1
C_{L_s}	lift coefficient of surface to which the main control surface is attached	6.3.4
$\left(\Delta C_L\right)_{SE}$	increment in lift coefficient, accounting for the direct influence of the wing shock-expansion field	4.4.1
$\left(\Delta C_L\right)_T$	increment in lift coefficient due to angle of attack of thrust axis	4.6 4.6.1 4.6.4
$\Delta C_{L_{tc}}$	lift loss due to tab	6.3.4
$\Delta C_{L_{trim}}$	incremental lift coefficient required for trim	4.5.3.2
C_{L_V}	vertical-tail lift coefficient	6.3.4
C_{L_W}	1. wing lift coefficient with power effects	4.6 4.6.4
	2. wing lift coefficient, including tab and control deflections	6.3.4
$C_{L_{WB}}$	wing-body lift coefficient in absence of ground plane	4.5.3.2 4.7 4.7.3
$\left(\Delta C_{L_{WB}}\right)_G$	increment in wing-body lift coefficient in the presence of the ground	4.7 4.7.3
$C_{L_{W''(v)}}$	contribution to the lift coefficient due to the effect of the forward-surface vortices on the aft surface	4.5.1.2
C_{L_α}	lift-curve slope, rate of change of lift coefficient with angle of attack, $\frac{dC_L}{d\alpha}$	Several
ΔC_{L_α}	increment in lift-curve slope	4.3.1.2
$\left(\Delta C_L\right)_{\Delta \alpha_W}$	increment in wing lift coefficient due to change in angle of attack induced by propeller flow field	4.6 4.6.1 4.6.3
$C_{L_{\alpha=0}}$	lift coefficient where $\alpha \approx 0$	4.1.3.3
$\left(C_{L_\alpha}\right)'$	1. complete lift-curve slope of forward panel and body, including interferences	4.5.2.1
	2. lift-curve slope of forward panel	4.5.1.2 7.4.4.1
$\left(C_{L_\alpha}\right)''$	1. lift-curve slope of aft panel, including wing-body interference effects	4.5.2.1
	2. lift-curve slope of aft panel	4.5.1.2

SYMBOL	DEFINITION	SECTIONS
$(C_{L_\alpha})_a$	value of the derivative at M_a	4.1.3.2
$(C_{L_\alpha})_B$	lift-curve slope of body	7.3.1.1 7.3.4.1
$(C_{L_\alpha})_b$	value of the derivative at M_b	4.1.3.2
$(C_{L_\alpha})_{basic}$	low-lift-region lift-curve slope, including thickness effects	4.1.3.2 4.1.4.3
$(C_{L_\alpha})_{B(W)}$ or $C_{L_{\alpha_{B(W)}}}$	lift-curve slope of body in presence of wing	4.3.2.2 4.5.2.1 4.5.3.2
$(C_{L_\alpha})_{C_L}$	value of the derivative at a given lift coefficient	5.1.2.2 7.1.2.2 7.3.2.2
$(C_{L_\alpha})_e$	lift-curve slope of the exposed wing	Several
$(C_{L_\alpha})'_e, (C_{L_\alpha})''_e$	lift-curve slopes of the exposed forward and aft panels, respectively	Several
$(C_{L_\alpha})_{fb}$	value of derivative at M_{fb}	4.1.3.2
$C_{L_{\alpha_H}}$	lift-curve slope of the horizontal surface	Several
$(C_{L_{\alpha_H}})_e$	lift-curve slope of the exposed horizontal surface	6.2.1.2
$(C_{L_{\alpha_H}})_{M_H}$	lift-curve slope of the horizontal tail operating at the local Mach number of the flow in the vicinity of the horizontal tail	4.5.1.2
$(C_{L_{\alpha_H}})_{M_\infty}$	lift-curve slope of the isolated horizontal tail at the free-stream Mach number	4.5.1.2
$(C_{L_\alpha})_i$	lift-curve slope of the inboard panel of wing	4.1.4.2 5.1.2.1
$(C_{L_\alpha})_{limit}$	limiting value of lift-curve slope	4.1.3.2
$(C_{L_\alpha})_{\substack{low\\speed}}$ or $\left(\frac{dC_L}{d\alpha}\right)_{\substack{low\\speed}}$	lift-curve slope at low speeds	4.4.1
$(C_{L_\alpha})_M$	value of derivative at a given Mach number	Several

SYMBOL	DEFINITION	SECTIONS
$\left(C_{L_\alpha}\right)_M$ or $\left(\frac{dC_L}{d\alpha}\right)_M$	lift-curve slope at high subsonic Mach numbers	4.4.1
$\left(C_{L_\alpha}\right)_{M_{cr}}$	value of derivative at the critical Mach number	7.1.1.2
$\left(C_{L_\alpha}\right)_N$	value of derivative for nose of body	Several
$C_{L_{\alpha_o}}$	power-off lift-curve slope	9.2.1
$\left(C_{L_\alpha}\right)_o'$	lift-curve slope of the constructed outboard panel of wing	4.1.4.2 5.1.2.1
$\left(C_{L_\alpha}\right)_p$	lift-curve slope of isolated vertical panel mounted on a reflection plane	5.3.1.1
$\left(C_{L_\alpha}\right)_{pred}$	lift-curve slope of cranked wing, predicted by double-delta-wing method	4.1.3.2
$\left(C_{L_\alpha}\right)_{theory}$	value of derivative derived from theory	4.1.3.2
$\left(C_{L_\alpha}\right)_U$	lift-curve slope of isolated lower vertical panel mounted on a reflection plane (the aspect ratio is taken as twice the aspect ratio defined by the average exposed span and exposed area)	Several
$\left(C_{L_\alpha}\right)_V$	1. lift-curve slope of isolated upper vertical panel with effective aspect ratio defined by Equation 5.3.1.1-a	5.3.1.1 5.6.1.1
	2. lift-curve slope of isolated upper vertical panel mounted on a reflection plane (the aspect ratio is taken as twice the aspect ratio defined by the average exposed span and exposed area)	Several
$\left(C_{L_\alpha}\right)_W$	lift-curve slope of the wing	4.3.1.2 4.3.1.3 4.3.3.2
$\left(C_{L_\alpha}\right)_{WB}$	lift-curve slope of the wing-body combination	4.2.2.1 4.3.1.2 4.7 4.7.1
$\left(C_{L_\alpha}\right)_{W\,(B)}$	lift-curve slope of wing in presence of body	4.3.2.2 4.5.2.1
$\left(C_{L_\alpha}\right)_{W_e\,(B)}$	lift-curve slope of the exposed wing in presence of body	4.3.1.2
$\left(C_{L_\alpha}\right)_{W''\,(v)}$	contribution to the lift-curve slope due to the effect of the forward-surface vortices on the aft surface	Several
$\left(C_{L_\alpha}\right)_\delta$	lift-curve slope of flap-deflected wing	6.1.4.2

SYMBOL	DEFINITION	SECTIONS
$\left(C_{L_\alpha}\right)_{\delta=0}$	lift-curve slope of flap-retracted wing	6.1.4.2
$\left(C_{L_\alpha}\right)_{II}, \left(C_{L_\alpha}\right)_{III}$	total lift-curve slopes between $C_{L_{II}}$ and $C_{L_{III}}$, and beyond $C_{L_{III}}$, respectively, (see Sketch (b), Section 4.1.3.2)	4.1.3.2 4.1.4.3
$\delta C_{L_{\alpha_{II}}}, \delta C_{L_{\alpha_{III}}}$	incremental increase in lift-curve slopes starting at $C_{L_{II}}$ and $C_{L_{III}}$, respectively, (see Sketch (b), Section 4.1.3.2)	4.1.3.2
$\frac{\left(C_{L_\alpha}\right)_{test}}{\left(C_{L_\alpha}\right)_{pred}}$	correction factor for subsonic lift-curve slope of cranked wings	4.1.3.2
$C_{L_{\dot\alpha}}$	change in lift coefficient with variation in rate of change of angle of attack, $\frac{\partial C_L}{\partial\left(\frac{\dot\alpha\,\bar c}{2V_\infty}\right)}$	Several
$\left(C_{L_{\dot\alpha}}\right)_B$	value of derivative for body	7.3.4.1 7.4.4.1
$\left(C_{L_{\dot\alpha}}\right)_e$	value of derivative for exposed wing	7.3.4.1 7.3.4.2
$\left(C_{L_{\dot\alpha}}\right)_e''$	contribution of exposed aft panel to acceleration derivative $C_{L_{\dot\alpha}}$	7.4.4.1
$\left(C_{L_{\dot\alpha}}\right)_W$	value of derivative for wing	7.3.4.1
$\left(C_{L_{\dot\alpha}}\right)_{WB}$	value of derivative for wing-body combination	7.3.4.1 7.4.4.1
$\left(C_{L_{\dot\alpha}}\right)_1, \left(C_{L_{\dot\alpha}}\right)_2$	components of the wing contribution to $C_{L_{\dot\alpha}}$	7.1.4.1
C_{L_δ}	rate of change of lift coefficient with wing flap deflection at constant angle of attack, $\frac{d C_L}{d\delta}$	6.1.4.1 6.1.5.1
C_{L_δ}'	lift-effectiveness of one symmetric, straight-sided flap, based on flap area	6.1.4.1 6.1.5.1 6.2.1.1
$\left(\Delta C_L\right)_e$	increment in lift due to inflow velocity of the flow surrounding the jet	4.6 4.6.1 4.6.3
$C_{L_{II}}, C_{L_{III}}$	breaks in lift-curve slope (see Sketch (b), Section 4.1.3.2)	4.1.3.2 4.1.4.3
C_N	1. normal-force coefficient, $\frac{N}{qS}$	Several
	2. normal-force coefficient, $\frac{N}{\rho n^2 D^4}$	9.1

SYMBOL	DEFINITION	SECTIONS
ΔC_N	1. increment in normal-force coefficient	6.3.1
	2. increment in coefficient due to jet-pressure interference on vehicle surfaces	4.6.1
C_N'	1. pseudonormal-force coefficient defined by the equation $C_N' = \frac{C_L}{\cos \alpha}$	4.1.3 4.1.3.3 4.1.3.4 7.4.1.1 9.1
	2. normal-force coefficient based on free-stream velocity and propeller disk area, $\frac{N}{q_\infty S_p}$	
$\left[C_N' @ C_{L_{max}}\right]_e'$, $\left[C_N' @ C_{L_{max}}\right]_e''$	pseudonormal-force coefficients at $C_{L_{max}}$ for exposed forward and aft panels, respectively	4.5.1.2
$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT}$	ratio of normal-force coefficient for body of noncircular cross section to that for an equivalent body of circular cross section (same cross-sectional area) as determined by Newtonian impact theory	4.2.1.2 4.2.2.2
$\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB}$	ratio of normal-force coefficient for body of noncircular cross section to that for an equivalent body of circular cross section (same cross-sectional area) as determined by slender-body theory	4.2.1.2 4.2.2.2
$(C_N)_{\substack{cone \\ cyl}}$	coefficient for cone-cylinder	4.2.1.2 4.2.3.2
$(C_N)_e$	coefficient for exposed wing	4.3.1.3 4.3.1.4
$(\Delta C_N)_F$	increment in coefficient due to body flare	4.2.1.2 4.2.3.2
$(C_N)_N$	coefficient for nose	4.3.1.3 4.3.1.4
$(\Delta C_N)_N$	increment in coefficient due to body nose	4.2.1.2
C_{N_p}	propeller normal-force coefficient	4.6 4.6.4
C_{N_q}	pitching derivative, $\frac{\partial C_N}{\partial\left(\frac{q\bar{c}}{2V_\infty}\right)}$	7.2.1.1
C_{N_q}'	value of derivative for forward panel	7.2.1.1 7.2.1.2
$(C_N)_W$	coefficient for wing	4.3.1.3
$C_{N_{W''(v)}}$	contribution to the normal-force coefficient due to the effect of the forward-surface vortices on the aft surface	4.5.1.2
C_{N_α}	1. rate of change of normal-force coefficient with angle of attack, $\frac{d C_N}{d \alpha}$	Several
	2. value of derivative for forward panel	Several
	3. value of derivative for propeller	9.1.3

SYMBOL	DEFINITION	SECTIONS
ΔC_{N_α}	increment in normal-force-curve slope of a boattail following a semi-infinite cylinder	4.2.2.1
$\left(C_{N_\alpha}\right)_B$	1. value of derivative for the body	5.2.1.1 7.3.1.1 7.3.1.2 7.3.4.1
	2. value of derivative for the body nose, based on nose frontal area	4.3.2.2
$C_{N_{\alpha_{B\,(W)}}}$	value of derivative for the body in presence of the wing	4.3.2.2
$\left(C_{N_\alpha}\right)_{bw}$	normal-force-curve slope of the basic wing	4.1.3.2 5.1.2.1
$\left(C_{N_\alpha}\right)_E$	value of derivative for trailing-edge extension of double-delta and cranked wings	4.1.3.2
$\left(C_{N_\alpha}\right)_e$	value of derivative for exposed wing	4.3.1.3 4.3.1.4 4.3.2.2 7.3.1.1
$\left(C_{N_\alpha}\right)_e', \left(C_{N_\alpha}\right)_e''$	normal-force-curve slopes of the exposed forward and aft panels, respectively	Several
$\left[\left(C_{N_\alpha}\right)_e\right]_i$	normal-force-curve slope of exposed inboard panel of wing	4.3.2.2
$\left[\left(C_{N_\alpha}\right)_e\right]_{theory}$	theoretical value of derivative for exposed wing	4.3.1.2
$\left[\left(C_{N_\alpha}\right)_{e\ theory}\right]_i$	theoretical value of normal-force-curve slope of exposed inboard panel of wing	4.3.2.2
$\left(\Delta C_{N_\alpha}\right)_F$	increment in normal-force-curve slope of a flared body of revolution following a semi-infinite cylinder	4.2.1.1 4.2.2.1
$\left(C_{N_\alpha}\right)_g$	normal-force-curve slope of glove of double-delta and cranked wings	4.1.3.2 5.1.2.1
$\left(C_{N_{\alpha_H}}\right)_e$	normal-force-curve slope of the exposed horizontal surface	6.2.1.2
$\left(C_{N_\alpha}\right)_i$	normal-force-curve slope of inboard panel of wing	4.1.4.2
$C_{N'_{\alpha\,in}}$	propeller normal-force-curve slope with respect to inflow angle of attack at propeller disk	9.1.3
$\left(C_{N_\alpha}\right)_N$	normal-force-curve slope of nose of body based on total wing area	4.3.1.2 4.3.2.2
$\left(C_{N_\alpha}\right)_o'$	normal-force-curve slope of constructed outboard panel of wing	4.1.4.2
$\left(C_{N_\alpha}\right)_p$	1. propeller normal-force derivative	4.6 4.6.1 4.6.4
	2. normal-force-curve slope of isolated vertical panel mounted on a reflection plane	5.2.1.1

SYMBOL	DEFINITION	SECTIONS
$\left[\left(C_{N_\alpha}\right)_p\right]_{K_N=80.7}$	propeller normal-force derivative for $K_N=80.7$	4.6 4.6.1
$\left(C_{N_\alpha}\right)_{theory}$	theoretical val[illegible]f derivative	Several
$\left[\left(C_{N_\alpha}\right)_{theory}\right]_e$	theoretical value of normal-force-curve slope of exposed wing	4.3.2.2
$\left[\left(C_{N_\alpha}\right)_{theory}\right]_i$	theoretical value of normal-force-curve slope of inboard panel of wing	4.1.4.2
$\left[\left(C_{N_\alpha}\right)_{theory}\right]'_o$	theoretical value of normal-force-curve slope of constructed outboard panel of wing	4.1.4.2 4.3.2.2
$\left(C_{N_\alpha}\right)_U$	normal-force-curve slope of isolated lower vertical panel mounted on a reflection plane (the aspect ratio is taken as twice the aspect ratio determined by the average exposed span and exposed area)	Several
$\left(C_{N_\alpha}\right)_V$	normal-force-curve slope of isolated upper vertical panel mounted on a reflection plane (the aspect ratio is taken as twice the aspect ratio determined by the average exposed span and exposed area)	Several
$C_{N_{\alpha_{W(B)}}}$	normal-force-curve slope of exposed wing in presence of the body	4.3.2.2
$\left(C_{N_\alpha}\right)_1, \left(C_{N_\alpha}\right)_2$	normal-force-curve slopes for constructed panels of non-straight-tapered wings	4.1.3.2 5.1.2.1
$\left(\frac{dC_N}{d\alpha}\right)_{\alpha=0}$	linear normal-force-curve slope for propeller	9.1.3
$C_{N_{\alpha\alpha}}$	nonlinear increment in normal-force coefficient	4.1.3.3 4.1.3.4 4.3.1.3
$\Delta C_{N_{\alpha\alpha}}$	incremental value of coefficient	4.1.3.3
$C_{N'_{\alpha\alpha}}$	value of coefficient at end of shock-detachment transition region	4.1.3.3
$C^*_{N_{\alpha\alpha}}$	value of coefficient at incipient shock separation	4.1.3.3
$\left(C_{N_{\alpha\alpha}}\right)'_e$, $\left(C_{N_{\alpha\alpha}}\right)''_e$	increments in coefficient at $C_{L_{max}}$ for exposed forward and aft surface, respectively	4.5.1.2
$\left(\Delta C_{N_{\alpha\alpha}}\right)'_e$, $\left(\Delta C_{N_{\alpha\alpha}}\right)''_e$	incremental values of coefficient for exposed forward and aft panels, respectively	4.5.1.2

SYMBOL	DEFINITION	SECTIONS
$\left(C_{N_{\alpha\alpha}}\right)_{ref}$	increment in coefficient at $C_{L_{max}}$	4.1.3.3
$\left[\left(C_{N_{\alpha\alpha}}\right)_{ref}\right]'_e$, $\left[\left(C_{N_{\alpha\alpha}}\right)_{ref}\right]''_e$	values of derivatives at $C_{L_{max}}$ for exposed forward and aft panels, respectively	4.5.1.2
$\left[\left(C_{N_{\alpha\alpha}}\right)_{ref}\right]_{WB}$	value of derivative for wing-body combination	4.3.1.3
$\left(C_{N_{\alpha\alpha}}\right)_{theory}$	theoretical value of coefficient	4.1.3.3
$\left(\Delta C_{N_{\alpha\alpha}}\right)_{WB}$	value of increment for wing-body combination	4.3.1.3
$\left(C_{N_{\alpha\alpha}}\right)_{90}$	value of coefficient $\alpha = 90^o$	4.1.3.3
$C_{N_{\dot{\alpha}}}$	rate of change of normal-force coefficient with rate of change in angle of attack	7.2.2.1
$\left(C_{N_{\dot{\alpha}}}\right)_B$	value of derivative for body	7.3.4.1
$\left(C_{N_{\dot{\alpha}}}\right)_e$	value of derivative for exposed wing	7.3.4.1
$\left(C_{N_{\dot{\alpha}}}\right)_{WB}$	value of derivative for wing-body combination	7.3.4.1 7.4.4.1
$\left[\left(C_{N_{\dot{\alpha}}}\right)_1\right]_e$, $\left[\left(C_{N_{\dot{\alpha}}}\right)_2\right]_e$	components to the exposed-wing contribution $C_{N_{\dot{\alpha}}}$	7.3.4.1
$\left(C_{N_1}'\right)'_e$, $\left(C_{N_2}'\right)'_e$	pseudonormal-force coefficients of the exposed forward panel	4.5.1.2
$\left(C_{N_1}'\right)''_e$, $\left(C_{N_2}'\right)''_e$	pseudonormal-force coefficients of the exposed aft panel	4.5.1.2
C_T	thrust coefficient, $\frac{T}{\rho n^2 D^4}$	9.1 9.1.1 9.1.3

SYMBOL	DEFINITION	SECTIONS
C_X	axial-force coefficient	4.2.3.2
$(C_X)_{\alpha = 0}$	axial-force coefficient at zero angle of attack	4.2.3.2
$(C_X)_{\alpha = 180^\circ}$	axial-force coefficient at $\alpha = 180^\circ$	4.2.3.2
C_Y	total side-force coefficient	Several
C_{Y_B}	side-force coefficient of body	5.2.1.2 5.2.3.2
$C_{Y_{H(B)}}$	side-force coefficient of horizontal tail in the presence of the body	5.3.1.2 5.3.3.2 5.6.1.2 5.6.3.2
$C_{Y_{HVU(B)}}$	side-force coefficient of empennage on tail-body configuration	5.3.1.2
$C_{Y_{HVU(WB)}}$	side-force coefficient of empennage on wing-body-tail configuration	5.6.1.2
C_{Y_p}	rotary derivative, $\dfrac{dC_Y}{d\left(\dfrac{pb}{2V_\infty}\right)}$	Several
$(C_{Y_p})_{WB}$	wing-body contribution to the derivative	7.4.2.1
$(\Delta C_{Y_p})_\Gamma$	increment in derivative due to geometric dihedral	7.1.2.1
C_{Y_r}	rotary derivative, $\dfrac{dC_Y}{d\left(\dfrac{rb}{2V_\infty}\right)}$	7.1.3.1 7.1.3.2 7.3.3.1 7.4.3.1
$(C_{Y_r})_{WB}$	wing-body contribution to the derivative	7.4.3.1
C_{Y_U}	side-force coefficient of ventral fin on tail-body configuration	5.3.1.2 5.3.3.2 5.6.1.2
$C_{Y_{U(K,\phi)}}$	side-force coefficient of ventral fin due to interference and cross-coupling of α and β	5.3.1.2 5.6.1.2
$C_{Y_{U(\eta)}}$	side-force coefficient of ventral fin on wing-body-tail configuration	5.6.1.2 5.6.3.2
C_{Y_V}	side-force coefficient of upper vertical tail on tail-body configuration	5.3.1.2 5.3.3.2

SYMBOL	DEFINITION	SECTIONS
$C_{Y_{V(K,\phi)}}$	side-force coefficient of upper vertical tail due to interference and cross-coupling of α and β	5.3.1.2 5.6.1.2
$C_{Y_{V(\Gamma_B)}}$	side-force coefficient of upper vertical tail due to body vortices	5.3.1.2 5.6.1.2
$C_{Y_{V(\eta)}}$	side-force coefficient of upper vertical tail on wing-body-tail configuration	5.6.1.2 5.6.3.2
$C_{Y_{WB}}$	side-force coefficient of wing-body configuration	5.2.1.2 5.6.1.2
$C_{Y_{W(B)}}$	side-force coefficient of the wing in the presence of the body	5.2.1.2 5.2.3.2
$C_{Y_{WBHVU}}$	side-force coefficient of wing-body-tail configuration	5.6.1.2
C_{Y_β}	rate of change of side force with sideslip angle, $\frac{dC_Y}{d\beta}$	Several
$\left(C_{Y_\beta}\right)_B$	value of derivative for body	5.2.1.1 5.3.1.1 5.6.1.1
$\left(\Delta C_{Y_\beta}\right)_{H(BW)}$	increment in C_{Y_β} due to the horizontal tail in the presence of the wing and body	5.3.1.1 5.6.1.1
$\left(\Delta C_{Y_\beta}\right)_{H(BWU)}$	increment in C_{Y_β} due to the horizontal tail in the presence of the wing, body, and lower vertical tail	5.3.1.1
$\left(\Delta C_{Y_\beta}\right)_{HV(BWU)}$	increment in C_{Y_β} due to the horizontal tail and upper vertical tail in the presence of the wing, body, and lower vertical tail	5.3.1.1
$\left(\Delta C_{Y_\beta}\right)_p$	increment in C_{Y_β} due to panel in empennage	Several
$\left(C_{Y_\beta}\right)_U$	value of derivative for lower vertical panel	Several
$\left(\Delta C_{Y_\beta}\right)_{U(WBHV)}$	increment in C_{Y_β} due to lower vertical stabilizer in presence of wing, body, horizontal tail, and upper vertical stabilizer	Several
$\left(C_{Y_\beta}\right)_V$	value of derivative for upper vertical panel	Several
$\left(\Delta C_{Y_\beta}\right)_{V(BWUH)}$	increment in C_{Y_β} due to the upper vertical tail in the presence of the wing, body, lower vertical tail, and horizontal tail	Several
$\left(C_{Y_\beta}\right)_{V_{eff}}$	lift-curve slope of equivalent rectangular vertical panel	5.3.1.1 5.6.1.1

SYMBOL	DEFINITION	SECTIONS
$(\Delta C_{Y_\beta})_{V(WBH)}$	increment in C_{Y_β} due to upper vertical stabilizer in presence of wing, body, and horizontal tail	Several
$(C_{Y_\beta})_W$	value of derivative for wing	5.2.1.1
$(C_{Y_\beta})_{WB}$	value of derivative for wing-body combination	5.2.1.1 5.2.1.2 5.6.1.1
$(\Delta C_{Y_\beta})_\Gamma$	increment in C_{Y_β} due to geometric dihedral	5.2.1.1 5.6.1.1
C_f	skin-friction coefficient for incompressible flow	Several
$(C_f)_B$	turbulent flat-plate skin-friction coefficient of the body including roughness effects	4.3.3.1 4.5.3.1
C_{f_c}	skin-friction coefficient for compressible flow	4.2.3.1 7.4.1.1
$(C_f)_H$	turbulent flat-plate skin-friction coefficient of the horizontal-tail panel	4.5.3.1
$(C_f)_i$, $(C_f)_o$	skin-friction coefficients for incompressible flow of wing inboard and outboard panels, respectively	4.1.5.1
$(C_f)_{inc}$	incompressible, turbulent, flat-plate skin-friction coefficient, including roughness effects, as a function of Reynolds number based on total body length	4.2.3.1
$(C_f)_p$	turbulent flat-plate skin-friction coefficient based on the MAC of the exposed tail panel	4.5.3.1
$(C_f)_V$	turbulent flat-plate skin-friction coefficient of the vertical-tail panel	4.5.3.1
$(C_f)_W$	turbulent flat-plate skin-friction coefficient of the wing including roughness effects	4.3.3.1 4.5.3.1
$(C_{f_W})_i$, $(C_{f_W})_o$	turbulent flat-plate skin-friction coefficients of the wing inboard and outboard panels, respectively, including roughness effects	4.3.3.1
C_{f_0}	vacuum-thrust coefficient	6.3.2
C_h	hinge-moment coefficient, $\frac{\text{hinge moment}}{qS_f c_f}$	6.1.3.2
C_{h_c}	hinge-moment coefficient of control surface	6.3.4
$C_{h_{tc}}$	hinge-moment coefficient of control tab	6.3.4
C_{h_α}	rate of change of hinge moment with angle of attack at constant flap or control deflection, $\frac{d C_h}{d\alpha}$	6.1.6 6.1.6.1

SYMBOL	DEFINITION	SECTIONS
ΔC_{h_α}	increment in derivative accounting for induced-camber effects	6.1.6.1
$\left(C_{h_\alpha}\right)_{t/c}$	hinge-moment derivative for a symmetric, straight-sided control, based on twice the area-moment of the control about its hinge line	6.1.6.1
$\left(C_{h_\alpha}\right)_{t/c=0}$	supersonic flat-plate hinge-moment derivative	6.1.6.1
C_{h_δ}	rate of change of hinge moment with control-surface deflection at constant angle of attack, $\frac{dC_h}{d\delta}$	6.1.6 6.1.6.2
ΔC_{h_δ}	increment in derivative due to induced-camber effects	6.1.6.2
C'_{h_δ}	value of derivative for zero-thickness control surface	6.1.6.2
C_l	rolling-moment coefficient, $\frac{\text{rolling moment}}{qSb}$	Several
C_{l_p}	rotary derivative $\frac{dC_l}{d\left(\frac{pb}{2V_\infty}\right)}$	Several
$\left(C_{l_p}\right)_{C_L}$	value of derivative at a given lift coefficient	7.1.2.2 7.3.2.1 7.3.2.2 7.4.2.2
$\left(\Delta C_{l_p}\right)_{drag}$	increment in derivative due to drag	7.1.2.2 7.4.2.2
$\left(C_{l_p}\right)_H$	horizontal-tail contribution to the derivative	7.4.2.2
$\left(C_{l_p}\right)_{WB}$	wing-body contribution to the derivative	7.4.2.2
$\left(C_{l_p}\right)_\Gamma$	contribution to derivative due to geometric dihedral	7.1.2.2 7.3.2.1 7.3.2.2 7.4.2.2
$\left(C_{l_p}\right)_{\substack{\Gamma=0 \\ C_L=0}}$	derivative at zero lift of wing without dihedral	7.1.2.1 7.1.2.2 7.4.2.2
$\frac{\left(C_{l_p}\right)_{C_{D_L}}}{C_L^2}$	drag-due-to-lift roll-damping parameter	7.1.2.2 7.4.2.2

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{\beta C_{l_p}}{\kappa}\right)_{C_L=0}$	roll-damping parameter at zero lift	7.1.2.2
C_{l_r}	rotary derivative, $\frac{dC_l}{d\left(\frac{rb}{2V_\infty}\right)}$	7.1.3.2 7.3.3.2 7.4.3.2
ΔC_{l_r}	increment in derivative due to geometric dihedral	7.1.3.2
$\left(\Delta C_{l_r}\right)_{C_L}$	semiempirical correction factor used to extrapolate potential-flow values of C_{l_r} to higher lift coefficients	7.1.3.2
$\left(\Delta C_{l_r}\right)_{\substack{\text{side}\\ \text{force}}}$	increment in derivative due to wing side force	7.1.3.2
$\left(C_{l_r}\right)_{WB}$	wing-body contribution to the derivative	7.4.3.2
$\frac{\Delta C_{l_r}}{\Gamma}$	increment in C_{l_r} due to dihedral	7.1.3.2
$\frac{\Delta C_{l_r}}{\theta}$	increment in C_{l_r} due to wing twist	7.1.3.2
C_{l_β}	rate of change of rolling moment with sideslip angle, $\frac{dC_l}{d\beta}$	Several
ΔC_{l_β}	difference between calculated and test values of the derivative	5.1.2.1
$\left(\Delta C_{l_\beta}\right)_p$	increment in C_{l_β} due to panel present in empennage	5.3.2.1 7.4.3.2
$\left(\Delta C_{l_\beta}\right)_U$	increment in C_{l_β} for lower vertical panel	5.3.2.1
$\left(C_{l_\beta}\right)_V$	value of derivative for upper vertical panel	5.3.2.1
$\left(C_{l_\beta}\right)_{WB}$	value of derivative for wing-body combination	5.2.2.1 5.6.2.1
$\left(\Delta C_{l_\beta}\right)_{z_W}$	increment in derivative due to wing height	5.2.2.1 5.6.2.1

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{C_{l_\beta}}{C_L}\right)_A$	contribution of wing aspect ratio to C_{l_β}	5.1.2.1 5.2.2.1 5.6.2.1
$\left(\frac{C_{l_\beta}}{C_L}\right)_{\Lambda_{c/2}}$	contribution of wing sweep to C_{l_β}	5.1.2.1 5.2.2.1
$\left(\frac{C_{l_\beta}}{C_L}\right)_{\Lambda_i}$	contribution of sweep of inboard panel of wing to C_{l_β}	5.1.2.1
$\left(\frac{C_{l_\beta}}{C_L}\right)_{\Lambda'_o}$	contribution of sweep of constructed outboard panel of wing to C_{l_β}	5.1.2.1
$\frac{C_{l_\beta}}{\Gamma}$	dihedral effect on C_{l_β} for uniform geometric dihedral	5.1.2.1
$\left(\frac{C_{l_\beta}}{\Gamma}\right)_{C_L}$	value of parameter at a given lift coefficient	5.1.2.2 5.6.1.2
$\frac{\Delta C_{l_\beta}}{\theta \tan \Lambda_{c/4}}$	wing-twist correction factor	5.1.2.1
$\frac{\beta C_{l_\beta}}{\kappa\Gamma}$	rolling-moment-due-to-sideslip parameter for any symmetric, spanwise distribution of dihedral angle	5.1.2.1
C_{l_δ}	rate of change of rolling moment with control deflection, $\frac{dC_l}{d\delta}$	Several
C_{l_δ}	rolling-moment effectiveness of one symmetric, straight-sided control about its root-chord line	6.1.5.1 6.2.1.1
$C_{l_{\delta_{\perp HL}}}$	value of derivative for control deflection perpendicular to the hinge line	6.2.1.1
C_m	1. pitching-moment coefficient, $\frac{\text{pitching moment}}{qS\bar{c}}$	Several
	2. duct pitching-moment coefficient, $\frac{M}{q_\infty S_D c}$	9.3

SYMBOL	DEFINITION	SECTIONS
ΔC_m	1. increment in pitching-moment coefficient about root-chord midpoint due to leading-edge vortex	4.1.4.3
	2. increment in pitching-moment coefficient	6.1.5.1 6.3.1
$C_{m_{a/b}}$	pitching-moment coefficient of body having elliptical cross sections	4.2.2.2
$C_{m_{C_L}}$	pitching-moment derivative, $\frac{dC_m}{dC_L}$	4.1.4 4.1.4.2 4.3.2.2
$\frac{\Delta C'_m}{C_L}$	ratio of pitching-moment increment to lift increment for a full-span flap on a rectangular wing	6.1.5.1
$\left(\frac{dC_m}{dC_L}\right)_{theory}$	wing pitching-moment-curve slope uncorrected for thickness effects	4.1.4.2
ΔC_{m_f}	increment in coefficient due to flaps at constant angle of attack	6.1.5.1
$(\Delta C_m)_G$	increment in pitching-moment coefficient in the presence of the ground	4.7 4.7.3 4.7.4
$(\Delta C_m)_H$	total change in pitching-moment coefficient of horizontal tail	4.6 4.6.1
$(\Delta C_{m_H})_G$	increment in horizontal-tail pitching moment in the presence of the ground	4.7 4.7.3
$[(\Delta C_m)_{HL}]_{\Delta C_A}$	increment in pitching moment about the hinge line due to axial-force increment	6.3.1
$[(\Delta C_m)_{HL}]_{\Delta C_N}$	increment in pitching moment about the hinge line due to normal-force increment	6.3.1
$(\Delta C_{m_H})_q$	increment in coefficient due to change in dynamic pressure at horizontal tail due to propeller-power effects	4.6 4.6.1 4.6.3
$[C_{m_{H(WBV)}}]_{\alpha C_{L_{max}}}$	horizontal-tail pitching moment at stall angle of attack	4.5.1.3
$(\Delta C_{m_H})_\epsilon$	increment in coefficient due to change in downwash at horizontal tail due to propeller-power effects	4.6 4.6.1 4.6.3
$(\Delta C_m)_L$	increment in coefficient due to change in wing lift caused by propeller power	4.6 4.6.3
C_{m_m}	sum of wing section pitching-moment increments	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
$(\Delta C_{m\ MRP}$	increment in pitching moment about vehicle moment reference point	6.3.1
$(\Delta C_m)_{N_j}$	increment in coefficient due to normal force acting at jet inlet due to inclination of oncoming flow to thrust axis	4.6.3
$(\Delta C_m)_{N_p}$	increment in coefficient due to propeller normal force	4.6 4.6.3
$C_{m_o}(g)$	pitching-moment coefficient correction term	7.1.4.2 7.3.4.2
$(\Delta C_m)_{\substack{power \\ on}}$	total increment in vehicle pitching-moment coefficient at a given angle of attack due to propeller power effects	4.6.3
$(\Delta C_m)_q$	increment in coefficient due to change in propeller-slipstream dynamic pressure	4.6 4.6.3
C_{m_q}	rotary derivative, $\dfrac{\partial C_m}{\partial\left(\dfrac{q\bar{c}}{2V_\infty}\right)}$	Several
C_{m_q}'	1. value of derivative referred to body axis with origin at wing aerodynamic center	7.1.1.2
	2. pitching derivative of body segment based on base area and base diameter and referred to moment center at forward face of segment	7.2.1.2
C_{m_q}''	value of derivative referred to body axis with origin at wing leading-edge vertex	7.1.1.2
$(C_{m_q})_B$	value of derivative for body	7.3.1.2 7.4.1.2
$(C_{m_q})_e$	value of derivative for exposed wing	7.3.1.2
$(C_{m_q})_e'$	value of derivative for exposed forward panel	7.3.1.2 7.4.1.2
$(C_{m_q})_M$	value of derivative at given Mach number	7.1.1.2 7.3.1.2
$(C_{m_q})_{M_{cr}}$	value of derivative at the critical Mach number	7.1.1.2
$(C_{m_q})_W$	value of derivative for wing	7.3.1.2
$(C_{m_q})_{WB}$	value of derivative for wing-body combination	7.3.1.2 7.4.1.2
$(\Delta C_m)_T$	increment in coefficient due to direct thrust force	4.6 4.6.3
$\Delta C_{m\ trim}$	incremental pitching-moment coefficient required for trim	4.5.3.2
$C_{m_{WB}}$	wing-body pitching-moment coefficient, $\dfrac{\text{pitching moment}}{qS\bar{c}}$	4.5.3.2

SYMBOL	DEFINITION	SECTIONS
$\left(\Delta C_{m_{WB}}\right)_G$	increment in wing-body pitching moment in the presence of the ground	4.7 4.7.3
$\left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}}$	wing-body pitching moment at stall angle of attack	4.5.1.3.
C_{m_α}	rate of change of pitching-moment coefficient with angle of attack at constant flap deflection, $\frac{d C_m}{d \alpha}$	Several
C'_{m_α}	pitching-moment-curve slope for body segment	4.2.2.1 7.2.1.2
$\left(C_{m_\alpha}\right)_B$	value of derivative for body	4.3.2.1 7.3.1.2 7.3.4.2
$C_{m_{\dot\alpha}}$	rate of change of pitching-moment coefficient with rate of change of angle of attack, $\frac{\partial C_m}{\partial\left(\frac{\dot\alpha \bar c}{2 V_\infty}\right)}$	Several
$C''_{m_{\dot\alpha}}$	value of pitching derivative referred to body axis with origin at wing leading-edge vertex	7.1.4.2
$\left(C_{m_{\dot\alpha}}\right)_B$	contribution of body to acceleration derivative $C_{m_{\dot\alpha}}$	7.3.4.2 7.4.4.2
$\left(C_{m_{\dot\alpha}}\right)_e$	contribution of exposed wing to acceleration derivative $C_{m_{\dot\alpha}}$	7.3.4.2
$\left(C_{m_{\dot\alpha}}\right)'_e$	contribution of exposed forward panel to the acceleration derivative $C_{m_{\dot\alpha}}$	7.4.4.2
$\left(C_{m_{\dot\alpha}}\right)''_e$	contribution of exposed aft panel to the acceleration derivative $C_{m_{\dot\alpha}}$	7.3.4.2
$\left(C_{m_{\dot\alpha}}\right)_W$	contribution of wing to acceleration derivative $C_{m_{\dot\alpha}}$	7.3.4.2
$\left(C_{m_{\dot\alpha}}\right)_{WB}$	contribution of wing-body combination to acceleration derivative $C_{m_{\dot\alpha}}$	7.3.4.2 7.4.4.2
$\left(C_{m_{\dot\alpha}}\right)_1, \left(C_{m_{\dot\alpha}}\right)_2$	components of the wing contribution to $C_{m_{\dot\alpha}}$	7.1.4.2 7.3.4.2
$\left[\left(C_{m_{\dot\alpha}}\right)_1\right]_e$, $\left[\left(C_{m_{\dot\alpha}}\right)_2\right]_e$	components of the exposed wing contribution to $C_{m_{\dot\alpha}}$	7.3.4.2
C_{m_δ}	rate of change of pitching-moment coefficient with control or flap deflection at constant angle of attack, $\frac{d C_m}{d \delta}$	6.1.5.1
C'_{m_δ}	pitching-moment effectiveness for one symmetric, straight-sided control, based on twice its moment-area about the hinge line	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
$(\Delta C_m)_e$	increment in coefficient due to jet interference effects at the horizontal tail	4.6.3
C_{m_0}	pitching-moment coefficient at zero lift	4.1.4.1 4.1.4.3 4.6.3
ΔC_{m_0}	increment in pitching-moment coefficient at zero lift due to linear twist	4.1.4.1
$C_{m_0}(g)$	pitching-moment-coefficient correction term	7.1.4.2 7.3.4.2
$(C_{m_0})_{\text{area not immersed}}$	pitching-moment coefficient at zero lift for portion of vehicle not immersed in propeller slipstream	4.6 4.6.3
$(C_{m_0})_B$	body zero-lift pitching-moment coefficient without Mach-number effects	4.3.2.1
$(C_{m_0})_i$	pitching-moment coefficient at zero lift of portion of vehicle immersed in propeller slipstream	4.6 4.6.3
$(C_{m_0})_{\text{theory}}$	zero-lift pitching-moment coefficient uncorrected for thickness effects	4.1.4.1
$(C_{m_0})_W$	wing zero-lift pitching-moment coefficient	4.3.2.1
$(C_{m_0})_{WB}$	zero-lift pitching-moment coefficient of the wing-body combination	Several
$(C_{m_0})_{\text{wing-body}}$		
$(C_{m_0})_{\theta=0}$	pitching-moment coefficient at zero lift of untwisted, constant-section wing	4.1.4.1
$\frac{(C_{m_0})_M}{(C_{m_0})_{M=0}}$	Mach-number correction factor	4.3.2.1
C_n	yawing-moment coefficient, $\frac{N}{qSb}$	Several
ΔC_n	yawing moment due to aileron deflection	6.2.2.1
C_{n_B}	yawing-moment coefficient of body	5.2.3.2
$C_{n_{HVU(B)}}$	yawing-moment coefficient of empennage on tail-body configuration	5.3.3.2
$C_{n_{HVU(WB)}}$	yawing-moment coefficient of empennage on wing-body-tail configuration	5.6.3.2
C_{n_p}	rotary derivative, $\frac{dC_n}{d\left(\frac{pb}{2V_\infty}\right)}$	7.1.2.1 7.3.2.1 7.3.2.2 7.4.2.3

SYMBOL	DEFINITION	SECTIONS
$\left(C_{n_p}\right)_M$	value of derivative for a given Mach number	7.3.2.3
$\left(C_{n_p}\right)_{WB}$	wing-body contribution to the derivative	7.4.2.3
$\frac{C_{n_p}}{\alpha}$	supersonic yawing moment due to rolling referred to stability axes with origin at the center of gravity	7.1.2.3
$\left(\frac{C_{n_p}}{\alpha}\right)_{\text{body axis}}$	supersonic yawing moment due to rolling referred to body axes with origin at the wing apex	7.1.2.3
$\left(\frac{C_{n_p}}{\alpha}\right)_{1,2,3}$	supersonic yawing moment due to rolling components -- body axes	7.1.2.3
C_{n_r}	rotary derivative, $\frac{dC_n}{d\left(\frac{rb}{2V_\infty}\right)}$	7.1.3.3. 7.3.3.3 7.4.3.3
$\left(C_{n_r}\right)_{WB}$	wing-body contribution to the derivative	7.4.3.3
$\frac{C_{n_r}}{C_{D_0}}$	low-speed profile-drag yaw-damping parameter	7.1.3.3
$\frac{C_{n_r}}{C_L^2}$	low-speed drag-due-to-lift yaw-damping parameter	7.1.3.3
$C_{n_{VU(B)}}$	yawing-moment coefficient of vertical tail and ventral fin on tail-body configuration	5.3.3.2
$C_{n_{WB}}$	yawing-moment coefficient of wing-body combination	5.2.3.2 5.6.3.2
$C_{n_{WBHVU}}$	yawing-moment coefficient of wing-body-tail configuration	5.6.3.2
C_{n_β}	rate of change of yawing moment with sideslip angle, $\frac{dC_n}{d\beta}$	Several
$\left(\Delta C_{n_\beta}\right)_p$	increment in C_{n_β} due to panel in empennage	Several
$\left(\Delta C_{n_\beta}\right)_V$	increment in C_{n_β} for vertical panel	5.3.3.1
$\left(C_{n_\beta}\right)_W$	value of derivative for wing alone	5.2.3.1
$\left(C_{n_\beta}\right)_{WB}$	value of derivative for wing-body combination	5.2.3.1 5.2.3.2 5.6.3.1

SYMBOL	DEFINITION	SECTIONS
C_{n_δ}	rate of change of yawing moment with control deflection, $\frac{dC_n}{d\delta}$	6.2.2.2
C_p	pressure coefficient $\frac{p - p_\infty}{q_\infty}$	Several
$\Delta C_p, \Delta C_{p_1}$ ...	sums of the pressure coefficients acting on the two sides of a given surface	5.3.1.1
C_{p_b}	base pressure coefficient	4.2.3.1 4.5.3.1 4.6.4
$C_{p_{inc}}$	incipient pressure-rise coefficient	6.3.1
C_{p_o}	two-dimensional pressure coefficient	6.1.6.1
$C_{p_{stag}}$	stagnation-pressure coefficient	4.2.1.2 4.2.2.2
$\left(C_{p_\alpha}\right)_p$	plateau-pressure coefficient referred to local pressure upstream of interaction	6.3.1
$\left(C_{p_\alpha}\right)_{inc}$	incipient pressure-rise coefficient referred to local pressure upstream of interaction	6.3.1
$\left(C_{p_\alpha}\right)_2$	peak value of pressure coefficient referred to local pressure upstream of interaction	6.3.1
C_{p_u}	maximum negative upper-surface section pressure coefficient	4.1.3.2
C_{p_2}	plateau-pressure coefficient	6.3.2
C_{p_∞}	free-stream pressure coefficient	6.3.1
$\left(C_{p_\infty}\right)_p$	plateau-pressure coefficient referred to free-stream pressure	6.3.1
$\left(C_{p_\infty}\right)_\alpha$	local pressure coefficient upstream of interaction referred to free-stream pressure	6.3.1
$\left(C_{p_\infty}\right)_2$	peak value of pressure coefficient referred to free-stream pressure	6.3.1
C_x	drag coefficient	6.3.2
C_{λ_k}	lift contribution to wing section pitching-moment coefficient	6.1.5.1
C_μ	section nondimensional trailing-edge jet momentum coefficient	Several
C'_μ	section nondimensional trailing-edge jet momentum coefficient based on extended airfoil chord	Several

D. LOWER-CASE COEFFICIENTS AND DERIVATIVES

SYMBOL	DEFINITION	SECTIONS
c_d	section drag coefficient, $\frac{\text{drag}}{qc}$	Several
c_{d_c}	cross-flow drag coefficient of circular cylinder of infinite length normal to flow direction	Several
Δc_{d_f}	airfoil-section drag coefficient with flap deflected	6.1.7
c_h	section hinge moment	6.1.3.2
$c_{h_{f_\alpha}}$	flap section hinge moment due to change in angle of attack	6.1.3.1
$\left(c_{h_f}\right)_{\delta_f}$	flap section hinge moment due to flap deflection	6.1.3.2
$\left(c_{h_f}\right)_{\delta_t}$	section hinge-moment derivative of control surface due to tab deflection	6.1.3.3
$c_{h_{t_\alpha}}$	tab section hinge moment due to change in angle of attack	6.1.3.1
$\left(c_{h_t}\right)_{\delta_f}$	section hinge moment derivative of a tab due to control-surface deflection	6.1.3.4
$\left(c_{h_t}\right)_{\delta_t}$	tab section hinge moment due to tab deflection	6.1.3.2
c_{h_α}	rate of change of control section hinge-moment coefficient with angle of attack at control deflection, $\frac{dc_h}{d\alpha}$	6.1.3.1 6.1.3.2 6.1.6.1 6.1.6.2
Δc_{h_α}	increment in derivative accounting for finite control thickness at supersonic speeds	6.1.3.1
c'_{h_α}	hinge-moment derivative (see Page 6.1.3.1-3, Step 1)	6.1.3.1 6.1.6.1 6.1.6.2
c''_{h_α}	hinge-moment derivative (see Page 6.1.3.1-3, Step 2)	6.1.3.1 6.1.6.1
$\left(c_{h_\alpha}\right)_{\text{balance}}$	value of derivative for aerodynamically balanced control surface	6.1.3.1 6.1.6.1
$\left(c_{h_\alpha}\right)_{\text{low speed}}$	value of derivative uncorrected for compressibility	6.1.3.1
$\left(c_{h_\alpha}\right)_M$	value of derivative corrected for compressibility	6.1.3.1
$\left(c_{h_\alpha}\right)_{\text{theory}}$	theoretical value of derivative	6.1.3.1 6.1.6.1

SYMBOL	DEFINITION	SECTIONS
$\frac{\Delta c_{h_\alpha}}{t/c}$	thickness-correction factor for symmetric, circular-arc airfoils	6.1.3.1
c_{h_δ}	rate of change of hinge-moment coefficient with control deflection, $\frac{dc_h}{d\delta}$	6.1.3.2 6.1.6.2
$\Delta c_{h_{\dot\alpha}}$	increment in derivative accounting for thickness effects at supersonic speeds	6.1.3.1 6.1.3.2
c'_{h_δ}	hinge-moment derivative (see Page 6.1.3.2-3, Step 1)	6.1.3.2 6.1.6.2
c''_{h_δ}	hinge-moment derivative (see Page 6.1.3.2-4, Step 2)	6.1.3.2 6.1.6.2
$(c_{h_\delta})_{balance}$	value of derivative for an aerodynamically balanced control	6.1.3.2 6.1.6.2
$(c_{h_\delta})_{low\ speed}$	value of derivative uncorrected for compressibility	6.1.3.2
$(c_{h_\delta})_M$	value of derivative corrected for compressibility	6.1.3.2
$(c_{h_\delta})_{theory}$	theoretical value of derivative	6.1.3.2 6.1.6.2
$\frac{\Delta c_{h_\delta}}{t/c}$	thickness-correction factor for symmetric, circular-arc airfoils	6.1.3.1
c_ℓ	section lift coefficient, $\frac{lift}{qc}$	Several
Δc_ℓ	increment in section lift coefficient due to flap or control deflection	Several
c_{ℓ_i}	design lift coefficient	Several
$c_{\ell_{max}}$	section maximum lift coefficient	Several
$\Delta c_{\ell_{max}}$	increment in section maximum lift coefficient due to flap deflection	6.1.1 6.1.1.3 6.1.4.3
$\Delta_1 c_{\ell_{max}}$	increment in coefficient accounting for effect of camber for airfoils with maximum thickness at 30% chord	4.1.1.4 4.1.3.3
$\Delta_2 c_{\ell_{max}}$	increment in coefficient accounting for effect of camber for airfoils with maximum thickness at positions other than 30% chord	4.1.1.4 4.1.3.3
$\Delta_3 c_{\ell_{max}}$	increment in coefficient accounting for Reynolds-number effects	4.1.1.4 4.1.3.3
$\Delta_4 c_{\ell_{max}}$	increment in coefficient accounting for airfoil-roughness effects	4.1.1.4
$\Delta_5 c_{\ell_{max}}$	increment in coefficient accounting for Mach-number effects	4.1.1.4

SYMBOL	DEFINITION	SECTIONS
$(c_{\ell_{max}})_{base}$	base or reference value of coefficient	4.1.1.4 4.1.3.3
$(\Delta c_{\ell_{max}})_{base}$	base or reference value of coefficient	6.1.1.3 6.1.4.3
$(c_{\ell_{max}})'_e$	section maximum lift coefficient of exposed forward panel	4.1.5.2
c_{ℓ_α}	1. section lift-curve slope, rate of change of section lift coefficient with angle of attack at constant flap deflection, $\frac{dc_\ell}{d\alpha}$	Several
	2. lift-curve slope for wing of infinite span	Several
	3. section lift-curve slope for propeller blade	9.1.3
Δc_{ℓ_α}	increment in section lift-curve slope due to NACA roughness	4.1.1.2
c'_{ℓ_α}	jet-flap section lift-curve slope uncorrected for thickness effects	Several
$(c_{\ell_\alpha})_M$	lift-curve slope corrected for compressibility effects	Several
$(c_{\ell_\alpha})_{theory}$	theoretical value of derivative	Several
$(c_{\ell_\alpha})_\delta$	value of derivative for deflected control or flap conditions	6.1.1.1 6.1.1.2 6.1.5.1
$(c_{\ell_\alpha})_{\delta=0}$	value of derivative for unflapped airfoil, including compressibility effects	6.1.1.2
c_{ℓ_δ}	rate of change of section lift with flap or control deflection at constant angle of attack, $\frac{dc_\ell}{d\delta}$	Several
$c_{\ell_{\delta_a}}$	section lift effectiveness due to deflection of a hypothetical flap	6.1.2.1 6.1.5.1
$c_{\ell_{\delta_f}}$	rate of change of section lift coefficient due to flap deflection	6.1.1.1 6.1.2.1 6.1.4.1
$c_{\ell_{\delta_{f_1}}}, c_{\ell_{\delta_{f_2}}}, c_{\ell_{\delta_{f_i}}}$	theoretical lifting-efficiency factors for first, second, and i^{th} segments, respectively, of trailing-edge flaps	6.1.1.1 6.1.2.1
$c_{\ell_{\delta_j}}$	rate of change of section lift coefficient due to jet deflection	6.1.1.1 6.1.2.1 6.1.4.1 6.1.5.1
$c_{\ell_{\delta_{max}}}$	theoretical maximum lifting effectiveness	6.1.1.3

SYMBOL	DEFINITION	SECTIONS
$(c_{\ell_\delta})_{theory}$	theoretical value of derivative	Several
$(c_{\ell_\delta})_\alpha$	value of derivative at a given angle of attack	6.1.1.1 6.1.5.1
$c_{\ell_{\delta_\perp}}$	value of derivative for control or flap deflection measured perpendicular to hinge line	6.1.6.2
c_{ℓ_Λ}	incremental section lift coefficient due to control deflections	6.1.5.1
$c_{\ell_{\Lambda=0}}$	incremental section lift coefficient as function of span station, referred to basic load line	6.1.5.1
c_m	section pitching-moment coefficient with flaps retracted	6.1.2.1
Δc_m	increment in section pitching-moment coefficient near maximum lift due to flaps and controls	6.1.2.1 6.1.2.2 6.1.2.3 6.1.5.1
dc_m/dc_ℓ	wing section pitching-moment-curve slope	6.1.2.2
$c_{m_{c/4}}$	section pitching-moment coefficient measured about the quarter-chord point	4.1.1 6.1.2.2
Δc_{m_f}	increment in section pitching-moment coefficient at low angles of attack due to flaps and controls	6.1.5.1
c_{m_α}	rate of change of section pitching-moment coefficient with angle of attack, $\frac{dc_m}{d\alpha}$	6.1.2.1 6.1.2.2
Δc_{m_α}	pitching-moment increment due to airfoil angle of attack	6.1.2.1 6.1.5.1
c_{m_δ}	rate of change of section pitching-moment coefficient with flap deflection at constant angle of attack, $\frac{dc_m}{d\delta}$	6.1.2.1
c'_{m_δ}	theoretical flap pitching-moment effectiveness (about the leading edge)	6.1.2.1
$c_{m_{\delta_f}}$	flap pitching-moment effectiveness measured about the leading edge	6.1.2.1
$(\Delta c_m)_{\delta_f}$	pitching-moment increment due to trailing-edge flaps	6.1.2.1 6.1.5.1
$(\Delta c_m)_{\delta_{f_{LE}}}$	pitching-moment increment due to deflection of a leading-edge device	6.1.2.1 6.1.5.1
$c_{m_{\delta_j}}$	rate of change of pitching-moment coefficient measured about the leading edge with respect to the jet deflection	6.1.2.1
$(\Delta c_m)_{\delta_j}$	pitching-moment increment due to jet sheet acting at an angle to trailing-edge camber line	6.1.2.1 6.1.5.1
$c'_{m_{\delta_{LE}}}$	theoretical two-dimensional flap pitching-moment effectiveness about the leading edge	6.1.5.1

SYMBOL	DEFINITION	SECTIONS
c_{m_0}, $\left(c_{m_0}\right)_W$	section pitching-moment coefficient for zero lift	4.1.1 4.1.2.1 4.1.4.1 4.3.2.1
$\left(c_{m_0}\right)_{\text{area not immersed}}$	section pitching-moment coefficient for zero lift of the area not immersed in propeller slipstream	4.6.3
$\left(c_{m_0}\right)_{root}$	section pitching-moment coefficient at zero lift of root section	4.1.4.1
$\left(c_{m_0}\right)_{tip}$	section pitching-moment coefficient at zero lift of tip section	4.1.4.1
Δc_{m_3}, Δc_{m_4}	intermediate terms in determining pitching-moment increments due to leading-edge devices and angle of attack, respectively	6.1.2.1 6.1.5.1

E. PARTIAL DERIVATIVES

SYMBOL	DEFINITION	SECTIONS
$\frac{\partial C_D}{\partial M}$	slope of curve of C_D vs M	4.3.3.1 4.5.3.1
$\frac{\partial \alpha}{\partial \delta}$	rate of change of zero-lift angle of attack with flap deflection	Several
$\frac{\partial \epsilon}{\partial \alpha}$	downwash gradient acting on the aft surface	Several
$\frac{\partial \bar{\epsilon}}{\partial \alpha}$	average downwash gradient acting on the aft surface	4.2.2.1 4.5.1.1
$\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_{\text{low speed}}$	average downwash gradient acting on the tail at low speeds	4.4.1
$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_M$	downwash gradient acting on the tail at high subsonic Mach numbers	4.4.1
$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_v$	downwash gradient in the plane of symmetry at the height of the vortex core	4.4.1 4.5.1.1 7.4.4.1

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_{\infty}$	downwash gradient at infinity	4.4.1 4.5.1.1 7.4.4.1
$\frac{\partial \epsilon_p}{\partial \alpha_p}$	downwash parameter due to propeller	4.6 4.6.1 4.6.4
$\frac{\partial \epsilon_u}{\partial \alpha}$	upwash gradient in the plane of symmetry of an unswept wing	Several
$\frac{d\epsilon_{z_{slip}}}{\partial \alpha_{in}}$	induced upwash gradient due to propeller slipstream	9.1.3
$\frac{\partial \sigma}{\partial \beta}$	sidewash parameter	Several
$\left(\frac{\partial c_{h_f}}{\partial c_\ell}\right)_{\delta_t, \delta_f}$	change in section hinge-moment coefficient of a control surface due to lift variation, measured at constant values of tab and flap deflections	6.1.3.3
$\left(\frac{\partial c_{h_f}}{\partial \delta_t}\right)_{c_\ell, \delta_f}$	change in section hinge-moment coefficient of a control surface due to tab deflection, measured at constant values of lift and flap deflection	6.1.3.3
$\left(\frac{\partial c_{h_f}}{\partial \delta_t}\right)_{\alpha, \delta_f}$	change in section hinge-moment coefficient of a control surface due to tab deflection, measured at constant values of angle of attack and flap deflection	6.1.3.3
$\left(\frac{\partial c_{h_t}}{\partial c_\ell}\right)_{\delta_f, \delta_t}$	change in section hinge-moment coefficient of a tab due to lift variation, measured at constant values of flap and tab deflections	6.1.3.4
$\left(\frac{\partial c_{h_t}}{\partial \delta_f}\right)_{c_\ell, \delta_t}$	change in section hinge-moment coefficient of a tab due to control-surface deflection, measured at constant values of lift and tab deflection	6.1.3.4
$\left(\frac{\partial c_{h_t}}{\partial \delta_f}\right)_{\alpha, \delta_t}$	change in section hinge-moment coefficient of a tab due to control-surface deflection, measured at constant values of angle of attack and tab deflection	6.1.3.4

SYMBOL	DEFINITION	SECTIONS
$\left(\frac{\partial c_\ell}{\partial \alpha}\right)_{\delta_f, \delta_t}$	section lift-curve slope of a control surface at constant values of flap and tab deflections	6.1.3.3 6.1.3.4
$\left(\frac{\partial \alpha}{\partial \delta_f}\right)_{c_\ell, \delta_t}$	rate of change of angle of attack due to change in flap deflection at constant values of lift and tab deflection	6.1.3.4
$\left(\frac{\partial \alpha}{\partial \delta_t}\right)_{c_\ell, \delta_f}$	rate of change of angle of attack due to change in tab deflection at constant values of lift and flap deflection	6.1.3.3

2.2 WING PARAMETERS

2.2.1 SECTION PARAMETERS

Airfoil section parameters that are useful in estimating aerodynamic data are presented in this Section. An airfoil-designation summary that has general utility throughout the Handbook is given. Figure 2.2.1-6 gives the trailing-edge angle for standard airfoils. This parameter is used in estimating section lift-curve slopes and control derivatives. Figure 2.2.1-7 gives the leading-edge radius of standard airfoils. This parameter is not used in this Handbook but is used extensively as a correlation parameter in the literature. It is presented for convenience only. The parameter that is used in place of leading-edge radius in the Handbook is the Δ_y parameter (see definition on figure 2.2.1-8). This parameter has been found to be highly successful in correlating data, e.g., see Section 4.1.3.4. It is presented for standard airfoils in figure 2.2.1-8 .

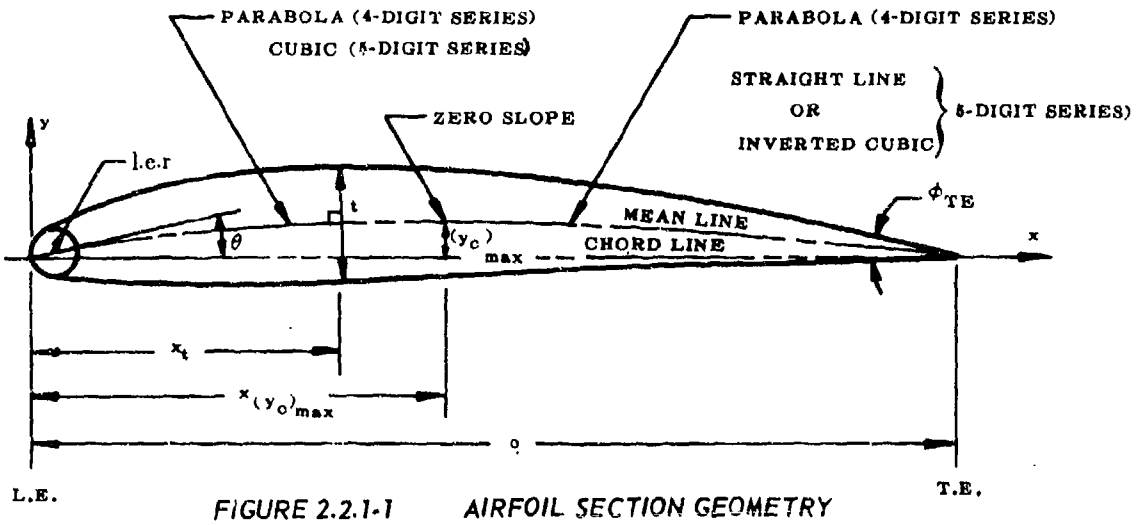

FIGURE 2.2.1-1 AIRFOIL SECTION GEOMETRY

BASIC SYMMETRIC AIRFOIL

- o = chord of airfoil section
- x = distance along chord measured from l.e.
- y = ordinate at some value of x (measured normal to and from the chord line for symmetric airfoils, measured normal to and from the mean line for cambered airfoils)
- y(x) = thickness distribution of airfoil
- $t = 2y_{max}$ = maximum thickness of airfoil
- x_t = position of maximum thickness
- l.e.r. = leading-edge radius
- ϕ_{TE} = trailing-edge angle (included angle between the tangents to the upper and lower surfaces at the trailing edge)

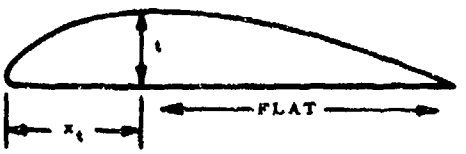
CAMBER MEAN LINE

- $(y_c)_{max}$ = maximum ordinate of mean line
- $y_c(x)$ = shape of mean line
- $x_{(y_c)_{max}}$ = position of maximum camber
- θ = slope of l.e.r. through l.e. equals the slope of the mean line at the l.e.
- c_ℓ = section lift coefficient
- c_{ℓ_i} = design section lift coefficient

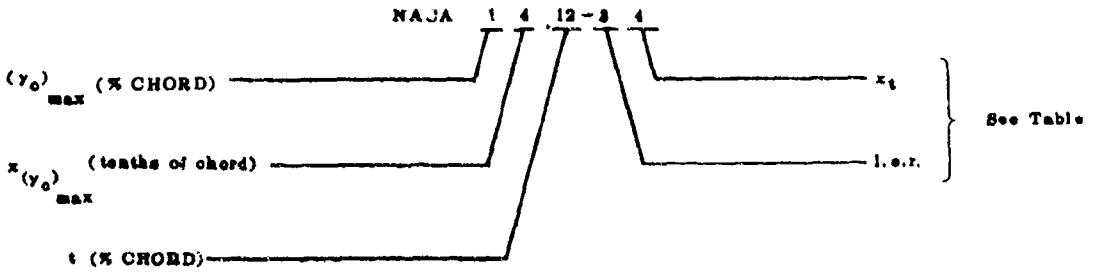
AIRFOIL SECTION DESIGNATION

"CLARK Y" AIRFOIL

x_t = 30% CHORD FOR ANY THICKNESS



NACA 4-DIGIT SERIES AIRFOILS



"Dash" numbers (numbers following a dash placed after the standard notation) are expressed only when l.e.r. and/or x_t are different from normal.

FIRST DASH NO.	l.e.r.	SECOND DASH NO.	x_t (% CHORD)
0	Sharp	2	20
3	¼ Normal	3	30 (Normal)
6	Normal	4	40
9	3 × Normal	5	50

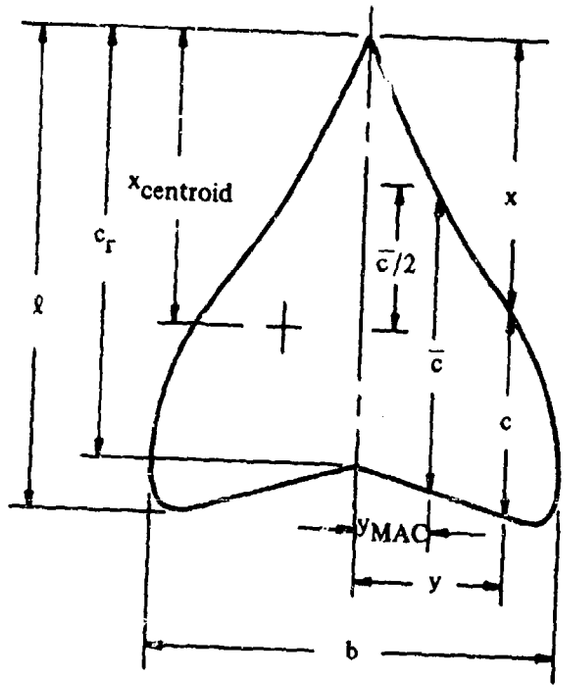
2.2.2 PLANFORM PARAMETERS

General planform parameters that are useful in estimating aerodynamic data are presented in this section. These parameters are given in equation form for conventional, straight-tapered wings and non-straight-tapered wings.

1. GENERAL PLANFORM PARAMETERS



Definitions

A	aspect ratio = b^2/S
b	wing span
$b/(2\ell)$	wing-slenderness parameter
c	chord (parallel to axis of symmetry) at any given span station y
$\bar{c}$	mean aerodynamic chord (MAC)

$$\bar{c} = \frac{2}{S} \int_0^{b/2} c^2 \, dy$$

c_r	root chord
ℓ	over-all length from wing apex to most aft point on trailing edge

p planform-shape parameter = $S/b\ell$

S wing area = $2\int_0^{b/2} c\,dy$

x chordwise location of leading edge at span station y

$x_{centroid}$ chordwise location of centroid of area (chordwise distance from apex to $\bar{c}/2$)

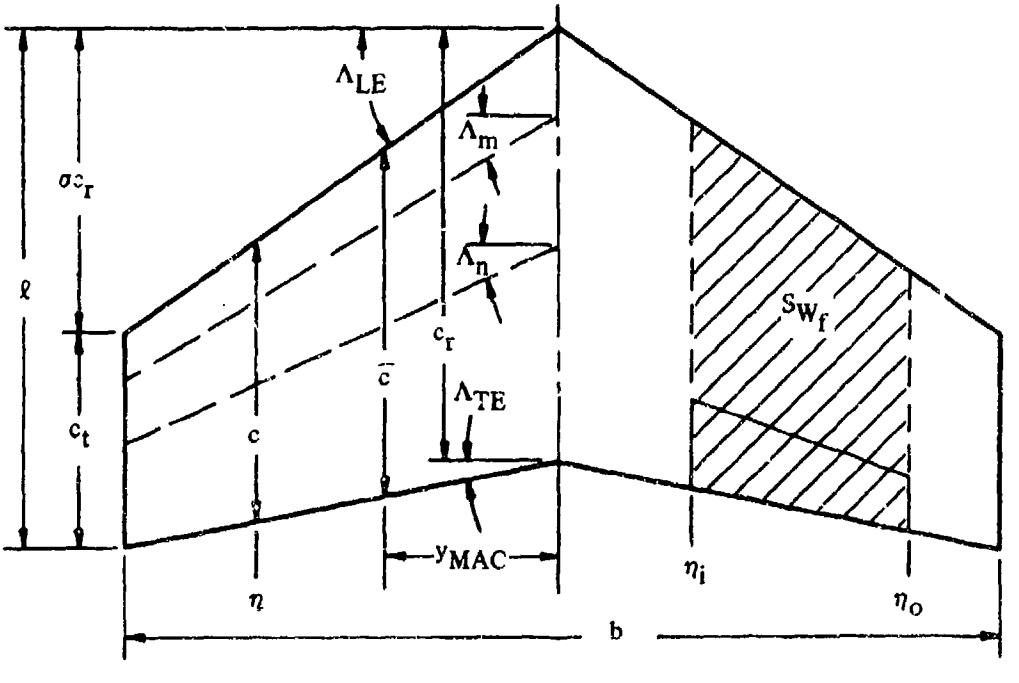
$$x_{centroid} = \frac{2}{S}\int_0^{b/2} c\left(x + \frac{c}{2}\right)dy$$

y general span station measured perpendicular to plane of symmetry

y_{MAC} spanwise location of MAC (equivalent to spanwise location of centroid of area)

$$y_{MAC} = \frac{2}{S}\int_0^{b/2} cy\,dy$$

2. CONVENTIONAL, STRAIGHT-TAPERED PLANFORM PARAMETERS



Definitions

b wing span

c chord of wing (parallel to axis of symmetry) at any given span station y

$\bar{c}$	mean aerodynamic chord (MAC)
c_r	root chord
c_t	tip chord
m, n	nondimensional chordwise stations in terms of c
S_{W_f}	wing area affected by trailing-edge deflection
y_{MAC}	spanwise location of MAC
η	nondimensional span station = y/(b/2)
η_i, η_o	nondimensional span stations at inboard and outboard edges of control, respectively.
λ	taper ratio = c_t/c_r
Λ_{LE}	sweep angle of leading edge
Λ_{TE}	sweep angle of trailing edge
Λ_m, Λ_n	sweep angles of arbitrary chordwise locations
σ	ratio of chordwise position of leading edge at tip to root chord length = (b/2) tan Λ_{LE}/c_r

Equations

$$A = \frac{b^2}{S} = \frac{2b}{c_r(1+\lambda)}$$

$$\bar{c} = \frac{2}{3} c_r \frac{1+\lambda+\lambda^2}{1+\lambda}$$

$$S = (b/2)c_r(1+\lambda)$$

$$S_{W_f} = \frac{b}{2}(\eta_o - \eta_i)\, c_r\, [2 - (1-\lambda)(\eta_i + \eta_o)]$$

$$\frac{x_{centroid}}{c_r} = \frac{1}{3}\left(\lambda + \sigma + \frac{1+\lambda\sigma}{1+\lambda}\right)$$

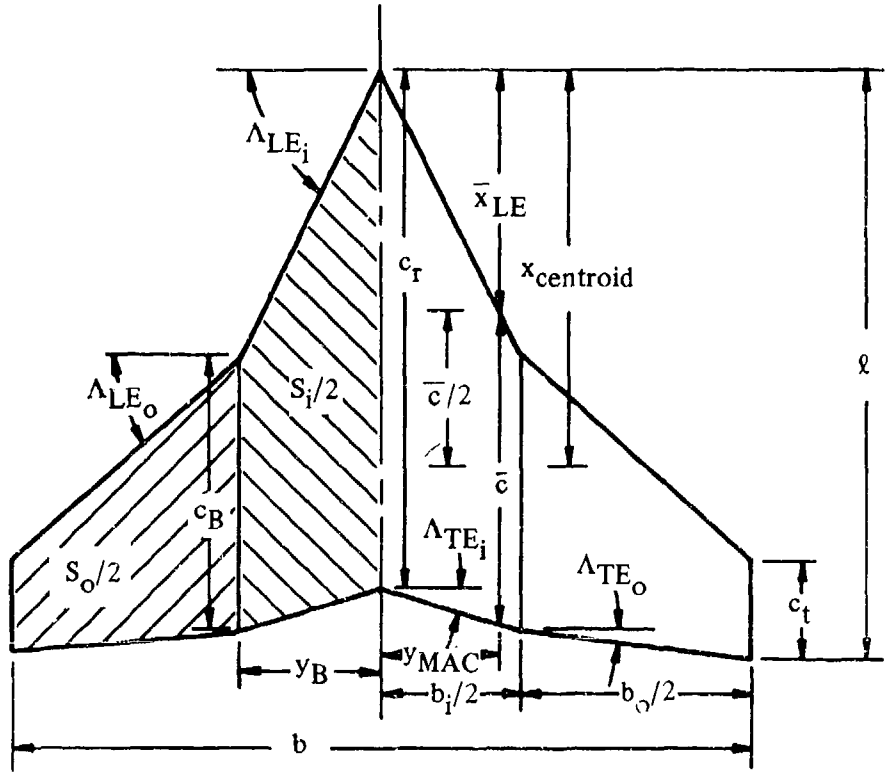
$$\frac{y_{MAC}}{b/2} = \frac{1 - \frac{\bar{c}}{c_r}}{1-\lambda} = \frac{1}{3}\left(\frac{1+2\lambda}{1+\lambda}\right)$$

$$\tan \Lambda_n = \tan \Lambda_m - \frac{4}{A}\left[(n-m)\frac{1-\lambda}{1+\lambda}\right]$$

$$\tan \Lambda_{LE} = \frac{4}{A} \quad (\lambda = 0)$$

$$\sigma = \frac{A}{4}(1 + \lambda) \tan \Lambda_{LE}$$

3. DOUBLE-DELTA AND CRANKED WING PLANFORM PARAMETERS



Definitions

b	wing span
b_i	span of planform formed by two inboard panels
b_o	span of planform formed by joining two outboard panels as an isolated wing
$\bar{c}$	mean aerodynamic chord (MAC)
c_B	chord at break span station
c_r	root chord
c_t	tip chord
S_i	total area of inboard panels
S_o	total area of outboard panels

$x_{centroid}$ chordwise location of centroid of area (chordwise distance from apex to $\bar{c}/2$)

$\bar{x}_{LE}$ chordwise distance from apex to leading edge of MAC

y_B spanwise location of break span station

y_{MAC} spanwise location of MAC

$\eta_B = y_B/(b/2)$

$\lambda = c_t/c_r$

$\lambda_i = c_B/c_r$

$\lambda_o = c_t/c_B$

Subscripts

B refers to span station when leading edges and/or trailing edges change sweep angles

i, o refer to inboard and outboard panels, respectively

Equations

$$A = \frac{b^2}{S} = \frac{2b}{c_r\left[(1-\lambda)\eta_B + \lambda_i + \lambda\right]}$$

$$\bar{c} = \frac{2}{S}\int_0^{b/2} c^2\,dy = \frac{\bar{c}_i S_i + \bar{c}_o S_o}{S_i + S_o}$$

$$S = S_i + S_o = \frac{b^2}{A} = (b/2)c_r\left[(1-\lambda)\eta_B + \lambda_i + \lambda\right]$$

$$\frac{x_{centroid}}{c_r} = \frac{\bar{x}_{LE} + \bar{c}/2}{c_r}$$

$$\bar{x}_{LE} = \frac{\left(y_{MAC_i}\tan\Lambda_{LE_i}\right)S_i + \left(y_B\tan\Lambda_{LE_i} + y_{MAC_o}\tan\Lambda_{LE_o}\right)S_o}{S_i + S_o}$$

$$y_{MAC} = \frac{2}{S}\int_0^{b/2} cy\,dy = \frac{y_{MAC_i}S_i + \left(y_B + y_{MAC_o}\right)S_o}{S_i + S_o}$$

$$\eta_B = \frac{b_i}{b} = \frac{1}{1-\lambda}\left(\frac{2b}{Ac_r} - \lambda_i - \lambda\right) = \frac{1}{1-\lambda}\left(\frac{2S}{bc_r} - \lambda_i - \lambda\right)$$

2.3 BODY PARAMETERS

Charts for estimating body volumes and surface areas for various families of profiles are presented in this Section.

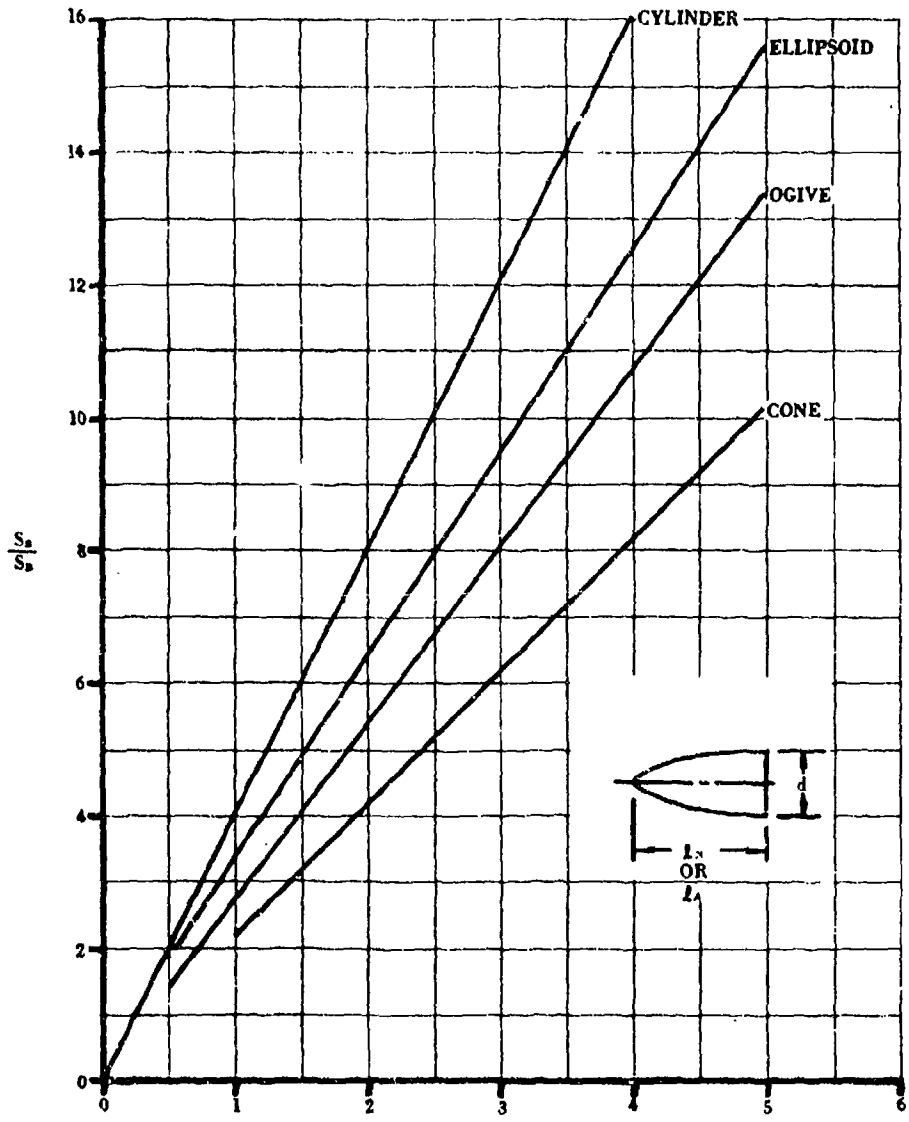


FIGURE 2.3-2 FOREBODY OR AFTERBODY WETTED AREA

3. EFFECTS OF EXTERNAL STORES

Methods are presented in this section for estimating the effects of externally mounted stores on aircraft stability characteristics. The methods predict the incremental effects due to the installed stores on the aircraft characteristics, not the isolated-store characteristics or the effect of the aircraft on the stores. Section 3 is subdivided as follows:

3.1 Effect of External Stores on Aircraft Lift
3.2 Effect of External Stores on Aircraft Drag
3.3 Effect of External Stores on Aircraft Neutral Point
3.4 Effect of External Stores on Aircraft Side Force
3.5 Effect of External Stores on Aircraft Yawing Moment
3.6 Effect of External Stores on Aircraft Rolling Moment

No suitable general methods have been developed for predicting the effect of stores on aircraft rolling moment, and therefore no Datcom methods have been provided in Section 3.6.

Methods for predicting effects of external stores can be grouped into theoretical, experimental, and empirical, or combinations thereof. Numerous attempts have been made to develop analytical methods for store effects. Reference 1 discusses many of the approaches and provides an extensive bibliography of theoretical methods. The methods tend to be complex and often require elaborate computer programs and extensive computations. Theoretical methods are basically in an early stage of development. They often require simplifications and assumptions which do not lend their application to be generalized over a wide range of loading configurations. Experimental methods include those which utilize increments from flight, wind-tunnel, ballistics or other test data. Access to data and time required for its interpretation are the primary limitations of experimental methods. Reference 1 discusses experimental approaches to computing store effects and provides a bibliography of methods and sources of data. Empirical methods have been developed and documented (References 2 and 3) which seem to provide the best general approach for estimating external-store effects. Empirical methods make use of test-data correlation and theoretical concepts to arrive at prediction equations. The Datcom methods are empirical in nature.

The Datcom methods are taken from Reference 3. Reference 3 is a very comprehensive effort that collected, reviewed, and correlated methods and existing test data to develop generalized prediction equations. Reference 3 also documents wind-tunnel tests which were designed specifically to provide a data base for empirical equation development. A very extensive list of references is also provided.

The Datcom methods in general require that the user provide only aircraft, store, and installation hardware geometric information in order to compute the aerodynamic effects of the store-aircraft combination. In some instances, the user is required to provide clean-aircraft data and isolated-store data. Because the methods are empirical in nature, the physical significance of some terms is not explained. The user should consult References 2 and 3 for additional insight into the method development.

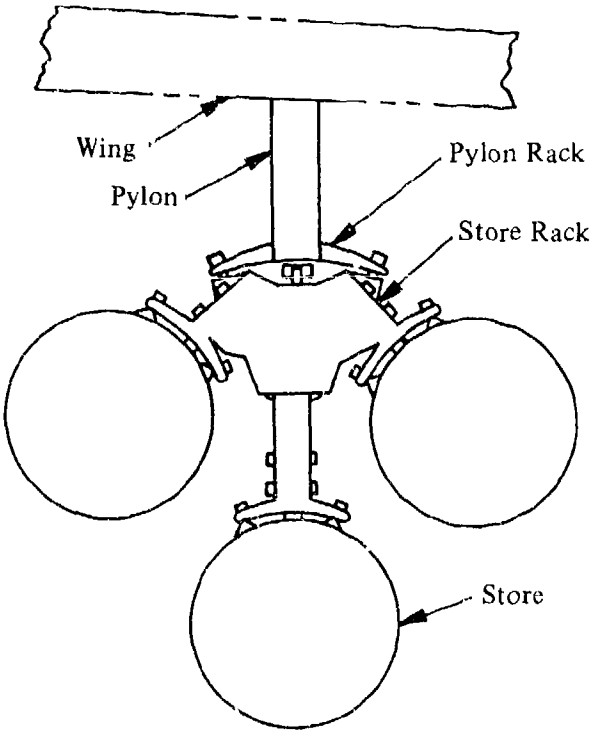
The methods are applicable for wing- and fuselage-mounted conventional stores which are symmetrically or asymmetrically loaded, and are mounted on conventional-type subsonic or supersonic aircraft. This comprises nearly all conventional store configurations encountered. In most instances the methods also account for multiple carriage, mixed and multiple loading cases, and interference effects involving adjacent stores and the fuselage. The methods have not been

substantiated for tip- or tangent-mounted wing stores. Specific limitations and assumptions involving configuration, flight envelope, and data base for method development are discussed in each of the individual sections.

Relatively little substantiation data is provided herein since the method substantiation is well documented in References 2 and 3. Expected accuracies of the methods are discussed in each section.

NOTATION

For the purposes of this section, a store installation refers to all armament-associated hardware including stores at one armament station and external to the clean aircraft. Installation hardware may include pylon, pylon rack, store rack, special adapters and launchers, sway braces, and stores. Typical installation hardware is illustrated in Sketch (a).



SKETCH (a)

Stores are carried in either a single or multiple carriage mode, and are either pylon- or tangent-mounted. In a single carriage mode, the store is mounted directly on the pylon rack or fuselage. The two multiple carriage modes considered by the Datcom methods are:

TER: Stores are mounted on a triple-ejector rack attached to the pylon rack or fuselage. This rack carries a maximum of three stores.

MER: Stores are mounted on a multiple-ejector rack attached to the pylon rack or fuselage. This rack carries a maximum of six stores.

A general notation list is included in this section for all sections included in Section 3. Since this notation list is quite extensive and the major portion of it includes notation peculiar to the Datcom Methods presented in Section 3, it is not integrated into the notation list presented as Section 2.1.

SYMBOL	DEFINITION
A_W	wing aspect ratio, based on total trapezoidal planform
A_1	longitudinal-location factor (side force)
A_2	store-size correlation factor (side force)
a_1, a_2, a_3	store-diameter correlation factors (drag)
B	basic-store-installation equivalent-parasite-drag area (ft^2) computed at M = 0.9
B_{ASC}	aft-store-cluster contribution (yawing moment)
B_e	protrusion of store fins beyond store body
B_{FSC}	forward-store-cluster contribution (yawing moment)
B_N	basic-store contribution term (side force)
B_P	pylon contribution (side force and yawing moment)
B_R	rack contribution (side force)
B_{SB}	store-body contribution (yawing moment)
B_{SF}	store-fin contribution (yawing moment)
B_X	pylon-longitudinal-location contribution (side force)
B_{xx}	empty-pylon factor (drag)
B_Y	pylon spanwise-location contribution (side force)

SYMBOL	DEFINITION
b_c	maximum vertical store-cluster span (in.), excluding protruding fins
b_e	exposed wing span
b_F	store-fin span (in.)
b_H	span of the aircraft tail
b_W	aircraft wing span
b_1, b_2, b_3	store-row Mach-correlation factors (drag)
C_{D_π}	isolated-store drag coefficient at zero lift
C_{D_0}	clean-aircraft zero-lift drag coefficient
C'_{D_0}	clean-aircraft drag-rise factor
C_L	clean-aircraft lift coefficient
$\left(C_{L_\alpha}\right)_{SB}$	store-body lift-curve slope
$\left(C_{L_\alpha}\right)_{SF}$	store-fin lift-curve slope
$C_{L_{\alpha_{S_{ij}}}}$	free-stream lift-curve slope of store j on installation i
$\left(C_{L_\alpha}\right)_{WB}$	wing-body, clean-aircraft lift-curve slope
C_{n_β}	rate of change of yawing-moment coefficient with sideslip angle
C_{Y_β}	rate of change of side-force coefficient with sideslip angle
ΔC_D	drag-coefficient increment due to external stores
ΔC_L	lift-coefficient increment due to external stores
$\Delta C_{L_{FS}}$	lift-coefficient increment due to fuselage-mounted stores

SYMBOL	DEFINITION
$\Delta C_{L_{WS}}$	lift-coefficient increment due to wing-mounted stores
ΔC_{n_β}	incremental change in C_{n_β}
ΔC_{Y_β}	incremental change in C_{Y_β}
c, c_i, c_{ij}	local wing chord at store or pylon station (in.)
$\bar{c}$	wing mean aerodynamic chord
$c_{p_{low}}$	pylon-bottom chord length (in.)
$c_{p_{top}}$	pylon-top chord length (in.) at wing-pylon juncture
c_r	wing root chord (in.)
D_B	zero-lift equivalent-parasite-drag area (ft^2) due to the basic store installation
D_{EM}	empty-MER equivalent-parasite-drag area (ft^2)
D_{ET}	empty-TER equivalent-parasite-drag area (ft^2)
D_{FLM}	fully loaded MER equivalent-parasite-drag area (ft^2)
D_{FLT}	fully loaded TER equivalent-parasite-drag area (ft^2)
D_{FR}	fuselage-rack equivalent-parasite-drag area (ft^2)
D_I	pylon-store-aircraft-interference equivalent-parasite-drag area (ft^2) at M = 0.9
D_{I_f}	equivalent-parasite-drag area (ft^2) at zero lift due to the mutual interference of store installation and adjacent fuselage
D_{ILP}	installed-loaded-pylon equivalent-parasite-drag area (ft^2)
D_{IM}	store-MER-aircraft-interference equivalent-parasite-drag area (ft^2)
D_{IMR}	installed-MER equivalent-parasite-drag area (ft^2)
D_{IS}	isolated-store equivalent-parasite-drag area (ft^2) at M = 0.90

SYMBOL	DEFINITION
D_{I_S}	zero-lift equivalent-parasite-drag area (ft^2) due to the mutual inteference of adjacent store installations (per pair of adjacent installations)
D_{IT}	store-TER-aircraft-interference equivalent-parasite-drag area (ft^2)
D_{ITR}	installed-TER equivalent-parasite-drag area (ft^2)
D_i	equivalent-parasite-drag area (ft^2) due to lift
D_{LPF}	equivalent-parasite-drag area (ft^2) due to the empty pylon on the fuselage
D_{MRF}	zero-lift equivalent-parasite-drag area (ft^2) due to a MER on the fuselage
D_{MSB}	MER sway-brace equivalent-parasite-drag area (ft^2)
D_{PR}	pylon-rack equivalent-parasite-drag area (ft^2)
D_{TSB}	TER sway-brace equivalent-parasite-drag area (ft^2)
D_X	store-to-aircraft-interference equivalent-parasite-drag area (ft^2)
d_c	minimum clearance between adjacent stores (in.)
d_S	maximum store diameter (in.)
d_{w_A}	maximum width (in.) of the aft-store installation
d_{w_L}	maximum width (in.) of the lead- (most forward) store installation
d_w	defined width (in.) of the store installation not including protruding fins
d_{wing}	distance (in.) from fuselage lower surface at store midpoint to average wing lower surface at wing root
E_u	pylon-height interference factor (drag)
$(FS)_{LE}$	fuselage station (in.) of the nose of the most forward store on the installation or the fuselage station of the leading edge of the pylon for the empty-pylon case
$(FS)_{ref}$	fuselage station (in.) of the moment reference point

SYMBOL	DEFINITION
F_R	ratio of store-fin area (projected onto a horizontal plane) to store-body planform area
$F_1(M)$	MER Mach-effect factor for fuselage-tangent-mounted or fuselage-pylon-mounted installations (pitching moment)
$F_1\left(\bar{x}_{SN_{ij}}\right)$	store longitudinal-placement parameter for TER or MER carriage (pitching moment)
$F_1\left(\bar{x}_{SN_{ij}}, F_R\right)$	store longitudinal-placement and fin-area-ratio parameter for wing pylon-mounted stores (pitching moment)
$F_2(M)$	MER Mach and store-station factor for fuselage tangent-mounted installations (pitching moment)
$F_2(M,j)$	Mach and store-station effect parameter (pitching moment)
$F_{21}\left(\bar{x}_{SN_{ij}}\right)$	store longitudinal-placement factor for wing-pylon-mounted single stores or MER carriage (pitching moment)
$F_{22}\left(\bar{z}_{ij}\right)$	store vertical-placement factor for wing pylon-mounted single stores or MER carriage (pitching moment)
$F_{23}\left(F_R\right)$	store-fin area-ratio factor for wing pylon-mounted single stores (pitching moment)
$F_{23}(M)$	Mach-effect factor for MER carriage (pitching moment)
$F_3(M,j)$	MER Mach and store-station-effect parameter (pitching moment)
h_f	overall fuselage height (in.)
h_p	average pylon height (in.)
I_{S_j}	MER installation neutral-point correlation factor (pitching moment)
K_{AWA}	longitudinal-location factor for multiple rack (lift)
K_{CJK}	pylon Mach-number correlation parameter (drag)
K_{D_1}	store frontal-area factor (drag)
K_{D_2}	wing-sweep-and-location factor (drag)

SYMBOL	DEFINITION
K_{D_3}	tandem-spacing factor (drag)
K_{D_4}	lateral-spacing factor (drag)
K_{D_5}	store-rows factor (drag)
K_{D_6}	stores-per-row factor (drag)
K_{D_7}	store longitudinal-location factor (drag)
K_F	fin constant (side force)
K_f	fuselage proximity-effect parameter (lift)
K_H	pylon-height factor (lift)
K_{HF}	lateral store-to-fuselage clearance parameter (lift)
K_{IF}	installation factor (drag)
K_M	Mach-effect factor (side force)
K_{NB}	nose-shape parameter (pitching moment)
K_{NI}	planform and store-location factor
K_p	pylon-height-effect parameter (lift)
K_{PC}	pylon constant (side force)
K_{PD}	pylon-depth factor (drag)
K_{SD}	store-depth factor (drag)
K_{S_M}	Mach-effect factor for K_{D_1} (drag)
K_{SPAN}	store-installation lateral-placement parameter (lift)
$K_{S_{ij}}$	loading-configuration factor (pitching moment)

SYMBOL	DEFINITION
K_{VF}	fuselage vertical clearance parameter (lift)
K_W	store-installation-width factor (lift)
K_{WING}	wing-location parameter (lift)
K_X	store-placement factor (lift)
K_{xx}	empty-pylon correlation ratio (drag)
K_y	store-installation-depth factor (side force)
K_{y_i}	horizontal-tail span-location factor (pitching moment)
K_{z_i}	horizontal-tail vertical-location factor (pitching moment)
K_Λ	wing-sweep-effect parameter (lift)
K_1	span-location factor (pitching moment)
K_2	longitudinal-correction factor (pitching moment)
K_3	Mach-number-correction factor (pitching moment)
L_{LE}	incremental-lift effect of the longitudinal location of multiple-mounted stores along the local wing chord (lift)
L_R	incremental-lift effect due to carriage-rack installation (lift)
$L_{\alpha_{FS}}$	fuselage-stores incremental-lift effect due to angle of attack (lift)
$L_{\alpha_{WS}}$	wing-stores incremental-lift effect due to aircraft angle of attack (lift)
ℓ_{AFT}	length (in.) of aft-store installation (drag)
ℓ_{ASC}	aft-store-cluster moment arm (in.) (yawing moment)
ℓ_{EM}	length of empty MER (in.)
ℓ_{ET}	length of empty TER (in.)

SYMBOL	DEFINITION
ℓ_m	moment arm (in.) from the moment reference point to the effective point of application of the side-force increment due to external stores (yawing moment)
ℓ_{m_1}	value of ℓ_m for the first of a pair of adjacent store installations (in.) (yawing moment)
ℓ_{m_2}	value of ℓ_m for the second of a pair of adjacent store installations (in.) (yawing moment)
ℓ_n	longitudinal distance (in.) from the store nose of the forward cluster to the store nose of the aft cluster
ℓ_P	pylon moment arm (in.) (yawing moment)
ℓ_S	store-body length (in.)
ℓ_{SB}	store-body moment arm (in.) (yawing moment)
ℓ_{SF}	longitudinal distance (in.) from the store nose to the intersection of the store-fin quarter chord and the store-fin 50% semispan
ℓ_{SP}	maximum store/pylon installation length (in.)
ℓ_x	longitudinal distance (in.) from $(FS)_{LE}$ to the point of side-force application, positive aft
ℓ_1	length of store installation 1.
ℓ_2	length of store installation 2.
M	Mach number
MER	multiple-ejector rack
M_{I_I}	MER adjacent-store separation factor (drag)
M_{I_S}	store-MER-aircraft-interference Mach-correlation factor (drag)
N_{A_i}	total number of asymmetrical external-store installations
N_F	number of store installations adjacent to the fuselage

SYMBOL	DEFINITION
N_I	total number of store installations on the aircraft
N_{I_f}	total number of fuselage-mounted store installations on the aircraft
N_P	total number of pairs of adjacent store installations carried
N_{S_M}	total number of stores attached to the MER
N_{S_T}	total number of stores attached to the TER
N_{S_i}	total number of pairs of symmetrical external-store installations
n_P	number of pylons
n_r	number of stores per row (fuselage mounting)
n_{s_i}	total number of store stations on installation i
P	clean-aircraft drag-rise factor
R_{A_M}	MER aft-longitudinal-placement term (drag)
R_{A_T}	TER aft-longitudinal-placement term (drag)
R_D	basic-stores-correlation factor (side force)
R_{F_M}	MER forward-longitudinal-placement factor (drag)
R_{F_T}	TER forward-longitudinal-placement factor (drag)
R_i	normalized incremental drag due to lift
R_{LC}	aft-store-cluster lateral-clearance factor (yawing moment)
R_{NEG}	adjacent-store interference factor (side force)
R_U	pylon-underside-roughness factor
S_B	maximum fuselage frontal area (ft^2)

SYMBOL	DEFINITION
S_F	store-fin area (in.^{2}) projected onto horizontal plane
S_P	maximum pylon cross-sectional (frontal) area (in.^{2})
S_p	store-body planform area (in.^{2})
S_W	aircraft wing reference area (ft^2)
S_{W_a}	1) affected wing area (in.^{2}) of both wings (for wing-mounted installations); 2) pseudo store installation planform area (in.^{2}) for both installations (for fuselage-mounted installations)
$S_{W_{a_B}}$	pseudo-store-body vertically projected area (in.^{2}) on one wing
$S_{W_{a_F}}$	vertically projected area (in.^{2}) on the wing of the unobstructed, exposed-fin areas of the stores at the given store station for one installation
S_π	store maximum cross-sectional area (ft^2)
T_A	transonic-supersonic correlation factor (drag)
TER	triple-ejector rack
T_F	tandem-stores factor (drag)
T_{I_I}	TER adjacent-store separation factor (drag)
T_{I_S}	store-TER-aircraft-interference Mach-correlation factor (drag)
T_N	distance from the nose of the aft-store installation to the tail of the lead-store installation (in.)
$t_{p_{max}}$	maximum pylon thickness (in.)
$U_{\bar{y}}$	lateral interference factor (drag)
$V_{\bar{x}}$	longitudinal interference factor (drag)
X_A	absolute longitudinal distance (in.) from the trailing edge of one store installation to the trailing edge of the adjacent store installation

SYMBOL	DEFINITION
X_F	absolute longitudinal distance (in.) from the nose of one store installation to the nose of the adjacent installation
X_{OL}	ratio of longitudinal spacing between tandem stores to the store length
x_{AFT}	longitudinal distance from the local wing trailing edge to the trailing edge of the store installation (in.) (or pylon trailing edge for the empty pylon case), positive in the aft direction
$x_{a.c.}$	wing-body aerodynamic-center location of the clean aircraft measured from the leading edge of the mean aerodynamic chord (in.)
x_{FWD}	longitudinal distance from the wing leading edge at the store location to the store/pylon nose (in.), positive for store nose aft of the wing leading edge
x_{ML_i}	distance (in.) from the local wing leading edge to the point midway between the pylon mounting lugs on installation i, positive in the aft direction
$x_{S_{ij}}$	distance (in.) from the leading edge of the mean aerodynamic chord $\bar{c}$, to the point midway between the mounting lugs of the installed store for store j on installation i, positive in the aft direction
$x_{SN_{ij}}$	distance (in.) from the local wing leading edge to nose of store j on installation i, positive in the aft direction
x_r	ratio of the distance between the aircraft nose and the store nose of the most forward store to the aircraft fuselage length
$\Delta x_{n.p.}$	total aircraft neutral-point shift due to external-store installations, positive for aft shift (in.)
$\Delta x_{n.p._1}$	shift in neutral point due to lift transfer from the stores to the clean aircraft, positive for aft shift (in.)
$\Delta x_{n.p._2}$	shift in neutral point due to the interference effects on the wing flow field, positive for aft shift (in.)
$\Delta x_{n.p._3}$	shift in neutral point due to the change in tail effectiveness caused by external stores, positive for aft shift (in.)
$\Delta x'_{n.p._2}$	neutral-point basic-interference-effect term
$\Delta x'_{n.p._3}$	neutral-point horizontal-tail term

SYMBOL	DEFINITION
Y_{A_β}	side-force contribution (ft^2/deg) per degree sideslip due to interference effects from a pair of adjacent external-store installations
Y_{B_β}	basic side-force contribution (ft^2/deg) per degree sideslip due to a symmetrical pair of external-store installations
$\left(Y_{B_\beta}\right)_1$	value of Y_{B_β} for the first of a pair of adjacent installations
$\left(Y_{B_\beta}\right)_2$	value of Y_{B_β} for the second of a pair of adjacent installations
Y_{OD}	ratio of minimum lateral distance between stores (excluding fins) to maximum store diameter
Y_S	minimum lateral clearance (in.) between adjacent store installations
y_i	spanwise distance from the fuselage centerline to the location of installation i
y_i'	spanwise distance from the outboard edge of the fuselage to the location of installation i
y_{ij}	spanwise distance from fuselage centerline to centerline of store j on installation i
$\bar{y}$	fraction of wing semispan location of store station measured from aircraft centerline
ΔY	minimum clearance (in.) between store installation and the fuselage
z	maximum depth of the store installation (in.) measured from the bottom surface of the wing
$\bar{z}$	ratio of vertical distance between average wing lower surface and store centerline to local wing chord
z_e	vertically projected length (in.) of the store installation on the aircraft wing
z_{ij}	distance (in.) from the wing lower surface to the centerline of store j on installation i, positive in the downward direction
z_{T_i}	vertical distance from wing lower surface at installation i to mid-line of the horizontal tail

SYMBOL	DEFINITION
z_w	distance from the top of the fuselage to the midpoint of the wing intersection with the fuselage (in.)
α	aircraft angle of attack
δ	equivalent-parasite-drag area (ft^2)
δ_{S_i}	configuration-related interference parameter (pitching moment)
θ_n	store nose-cone half-angle (deg)

3.1 EFFECT OF EXTERNAL STORES ON AIRCRAFT LIFT

Methods are presented in this section for estimating the change in aircraft lift due to external-store installations. The methods predict an incremental change in lift coefficient, based on wing reference area, which can be added to the clean-aircraft lift coefficient to obtain the aircraft-with-stores lift coefficient. These methods are taken from Reference 1 and are empirical in nature.

Section 3.1 is subdivided as follows:

Section 3.1.1 Lift Increment Due to Wing-Mounted Store Installations

Section 3.1.2 Lift Increment Due to Fuselage-Mounted Store Installations

Section 3.1.3 Total Lift Increment Due to External Stores

Section 3.1.3 presents the method for computing the total incremental lift coefficient due to symmetric and/or asymmetric loading configurations. That section will then refer the user to Section 3.1.1 and/or Section 3.1.2 as appropriate for the loading configuration being analyzed. Due to the nature of the method, the lift increments for wing and fuselage stores are computed separately for pairs of symmetrically-mounted store installations by the methods of Sections 3.1.1 and 3.1.2.

The Datcom methods are applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The methods are limited to the store-loading configurations and Mach-number ranges presented in Table 3.1-A. The methods are applicable to mixed loading configurations obtained by combining two or more loadings specified in Table 3.1-A. Additional limitations are specifically noted in each of the sections.

TABLE 3.1-A

LOADING AND MACH-NUMBER LIMITATIONS

Mounting Location	Carriage Mode	Mount/Loading Type	Mach-Number Range
Wing	Single	Pylon – Empty	0 → 2.0
		Pylon – Store	
	Multiple	Pylon – Empty MER	0 → 1.6
		Pylon – Full/Partial MER	
		Pylon – Empty TER	
		Pylon – Full/Partial TER	
Fuselage	Single	Tangent	0 → 2.0
		Pylon – Empty	
		Pylon – Store	
	Multiple	Tangent – Empty MER	0 → 1.6
		Tangent – Full/Partial MER	
		Tangent – Empty TER	
		Tangent – Full/Partial TER	
		Pylon – Empty MER	
		Pylon – Full/Partial MER	
		Pylon – Empty TER	
		Pylon – Full/Partial TER	

For most configurations the addition of wing-mounted stores results in a loss of aircraft lift in the subsonic-flight regime. The lift loss generally increases substantially through the transonic speed range, and often reverses to provide positive-lift increments at the higher supersonic speeds ($M > 1.6$).

1. Gallagher, R. D., Jimenez, G., Light, L. E., and Thames, F. C.: Technique for Predicting Aircraft Aerodynamic Effects Due to External Stores Carriage. AFFDL-TR-75-95, Volumes I and II, 1975. (U)

3.1.1 LIFT INCREMENT DUE TO WING-MOUNTED STORE INSTALLATIONS

A method is presented in this section for estimating the aircraft lift-coefficient increment due to wing-mounted store installations. The method as presented is for estimating the increment due to a pair of symmetric wing-mounted installations. The increment due to a single installation may also be obtained by simply using half the increment due to the pair of symmetric installations.

For most configurations the addition of wing-mounted stores results in a loss of aircraft lift in the subsonic speed range. The lift loss generally increases substantially through the transonic speed range, and often reverses to provide positive lift increments at the higher supersonic speeds.

The Datcom method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.1-A of the preceding section. Additional limitations and assumptions pertaining to the method are listed below:

1. The method is not applicable to wing-tip or wing-tangent-mounted stores.

2. The method has been verified for a Mach-number range between M = 0.6 and M = 2.0 with a few exceptions. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.

3. The method has not been verified for configurations in which flaps, slats or other flow disrupting devices are deployed.

4. The method gives the best results for an angle-of-attack range from 0 to 8^{O}, although the method can be used for higher angles of attack.

5. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

6. No method is provided to estimate fuselage and adjacent-store interference effects. These effects may be significant if the separation distances are less than 3 store diameters. Proximity to engine inlets may also be significant.

7. The method is applicable for sideslip angles less than 4^{O}.

The loading configuration capabilities of the method are given in Table 3.1.1-A. Each configuration is assigned a number which is referred to throughout the method. The method is applied separately to each single store installation or symmetrical pair of store installations.

TABLE 3.1.1-A

STORE CONFIGURATION SUMMARY

Configuration			Configuration Number
Mounting	Carriage	Loading	
Pylon	None	Empty	1
	Single	Single	1
Pylon	MER	Empty	2
		Pa. tially Loaded	2
		Full	2
Pylon	TER	Empty	3
		Partially Loaded	3
		Full	3

A. SUBSONIC

DATCOM METHOD

The incremental lift coefficient, based on wing reference area, due to a pair of symmetric wing-mounted external-store installations is given by Equation 3.1.1-a. (For a single installation, this value should be divided by two.)

$$\Delta C_{L_{WS}} = \frac{1}{S_W}\left[(L_R + L_{LE}\, K_{AWA})(K_\Lambda\, K_p + K_f) + L_{\alpha_{WS}}(\alpha - 4.0)\right] \qquad 3.1.1\text{-a}$$

where

S_W is the wing reference area (ft^2).

L_R is an incremental-lift effect due to carriage-rack installation.

For an empty pylon or a pylon-mounted, single-store installation (Configuration 1) L_R is presented over the Mach-number range from 0.6 through 2.0 in Figure 3.1.1-12.

For MER store loading (Configuration 2) or TER store loading (Configuration 3) L_R is presented at M = 0.6, 0.8, and 1.6 in Figures 3.1.1-13 and 3.1.1-14. The value of L_R between M = 0.6 and 0.8 may be obtained by linear interpolation. L_R at M = 1.6 is a single-point value. Over the Mach-number range from $M > 0.8$ to $M < 1.6$, $L_R = 0$ for Configurations 2 and 3.

The term L_R is presented on Figures 3.1.1-12 through 3.1.1-14 as a function of S_{W_a}

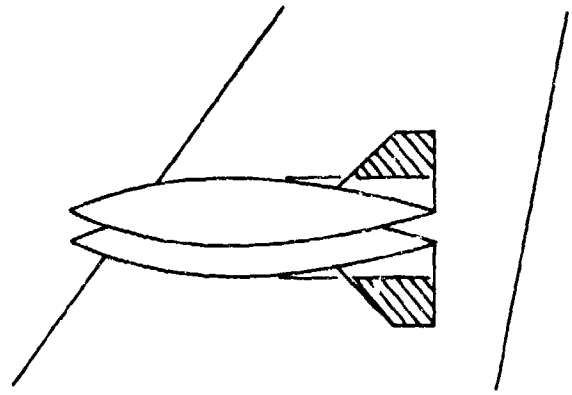
where

S_{W_a} is the affected wing area (in.^{2}) of both wings and is given by

$$S_{W_a} = 2\left(S_{W_{a_B}} + S_{W_{a_F}}\right) \qquad 3.1.1\text{-b}$$

where

$S_{W_{a_F}}$ is the vertically projected area (in.^{2}) on one wing of the unobstructed, exposed-fin areas of the stores at the given store station for one installation (See Sketch (a).).



SKETCH (a)

$S_{W_{a_B}}$ is the pseudo-store-body or pylon vertically projected area (in.^{2}) on one wing given by the following geometrical relationships:

1. For $x_{FWD} \geq 0$ and $c \geq (\ell_{SP} + x_{FWD})$:

$$S_{W_{a_B}} = \ell_{SP} d_w \qquad 3.1.1\text{-c}$$

2. For $x_{FWD} \geq 0$ and $c \leq (\ell_{SP} + x_{FWD})$:

$$S_{W_{a_B}} = (c - x_{FWD}) d_w \qquad 3.1.1\text{-d}$$

3. For $x_{FWD} < 0$ and $c < (\ell_{SP} + x_{FWD})$:

$$S_{W_{a_B}} = c d_w \qquad 3.1.1\text{-e}$$

4. For $x_{FWD} < 0$ and $c \geq (\ell_{SP} + x_{FWD})$:

$$S_{W_{a_B}} = (\ell_{SP} + x_{FWD}) d_w \qquad 3.1.1\text{-f}$$

where

x_{FWD} is the longitudinal distance (in.) from the local wing leading edge to the store/pylon nose, positive for store/pylon nose aft of the leading edge. (See Sketch (b).)

c is the local-wing chord (in.) at the store or pylon station. (See Sketch (b).)

ℓ_{SP} is the maximum store/pylon installation length (in.). (See Sketch (b).)

d_w is the defined width (in.) of the store installation, not including protruding fins, given by

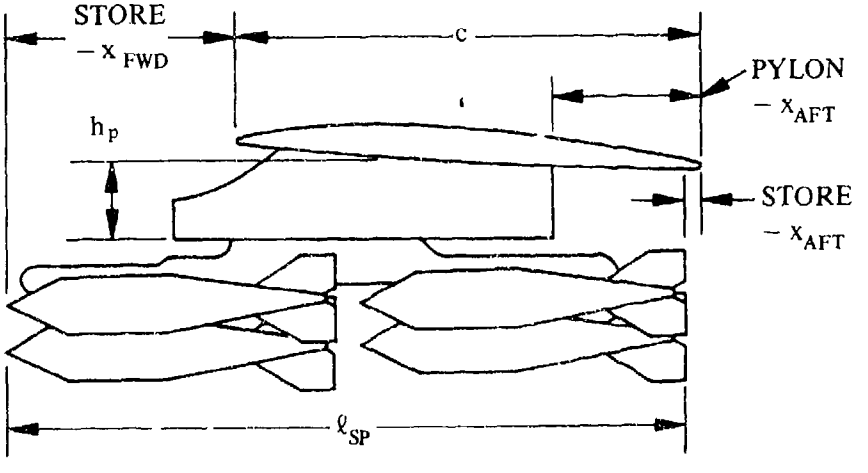
1. For an empty pylon:

$$d_w = 1.5 \text{ (maximum pylon width)} \qquad 3.1.1\text{-g}$$

2. For a single store:

$$d_w = d_S \qquad 3.1.1\text{-h}$$

(d_S is the maximum store diameter)



SKETCH (b)

L_{LE} is an incremental-lift effect of the longitudinal location of multiple-mounted stores along the local wing chord. For Configuration 1, $L_{LE} = 0$. For Configurations 2 and 3 $L_{LE} = 0$ at $M \leq 0.8$ and at $M = 1.6$. Over the Mach-number range from $M > 0.8$ to $M < 1.6$ L_{LE} is obtained from Figures 3.1.1-15 and 3.1.1-16 as a function of x_{AFT}/c. The value of x_{AFT} is the longitudinal distance (in.) from the local wing trailing edge to the trailing edge of the store installation (or pylon trailing edge for the empty pylon case), positive in the aft direction. (See Sketch (b).)

K_{AWA} is the longitudinal-location factor for multiple-rack carriage (Configurations 2 and 3) obtained from Figure 3.1.1-17. ($K_{AWA} = 0$ at $M \leq 0.8$ and at $M = 1.6$.)

K_{Λ} is the wing-sweep-effect parameter obtained from Figure 3.1.1-18a.(This parameter is a function of the wing leading-edge sweep angle Λ_{LE}.)

K_p is the pylon-height-effect parameter given by

$$K_p = 1 + K_H K_X K_W \qquad 3.1.1\text{-i}$$

where

K_H is a pylon-height factor obtained from Figure 3.1.1-18b as a function of the average pylon height, h_p (in.). (See Sketch (b).)

K_X is a store-placement factor obtained from Figure 3.1.1-19a as a function of x_{AFT}/c.

K_W is a store-installation-width factor obtained from Figure 3.1.1-19b as a function of h_p/d_w.

K_f is the fuselage proximity-effect parameter where

$$K_f = K_{HF} K_{VF} \qquad 3.1.1\text{-j}$$

and

K_{HF} is a lateral store-to-fuselage clearance parameter obtained from Figure 3.1.1-20b.

K_{VF} is a vertical clearance parameter obtained from Figure 3.1.1-20a.

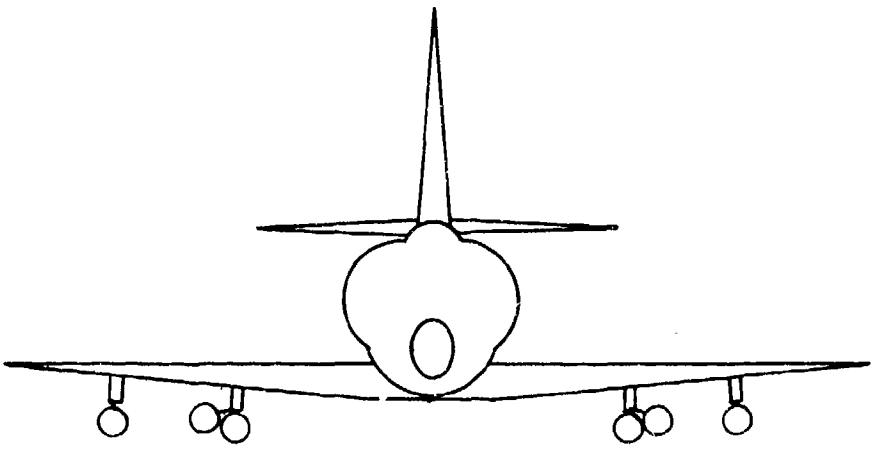
Note that for a low-wing configuration $K_{HF} = K_{VF} = 0$.

$L_{\alpha_{WS}}$ is an effect due to aircraft angle of attack obtained from Figures 3.1.1-21a through -21h as a function of store-installation type, Mach number, and x_{AFT}/c.

α is the aircraft angle of attack (deg).

Sample Problem

Given: A swept-wing subsonic fighter aircraft from Reference 2, symmetrically loaded as follows:



FRONT VIEW

Spanwise Station	Rack Type	Mounting	Store Type	No. of Stores	Configuration Number (Table 3.1.1-A)
Inboard Wing	TER	Pylon	500-lb Bomb	2	3
Outboard Wing	Single	Pylon	500-lb Bomb	1	1

Aircraft Data:

$S_W = 260\ ft^2$ $\quad$ c = 121.5 in. (at inboard sta.)

$\Lambda_{LE} = 42^o$ $\quad$ c = 37.8 in. (at outboard sta.)

Stores Data:

$d_S = 12$ in. $\quad$ $\ell_{SP} = 91.2$ in.

Installation Data:

Location	d_w	$\frac{x_{AFT}}{c}$	$\frac{x_{FWD}}{c}$	h_p	ℓ_{SP}
Inboard Wing	25.6 in.	−0.400	−0.158	11.2 in.	91.2 in.
Outboard Wing	12 in.	−0.210	−0.264	11.2 in.	91.2 in.

Additional Data:

$M = 0.8 \qquad \alpha = 8^{O}$

Geometry of unobstructed, exposed-fin areas required for calculation of $S_{W_{a_F}}$ is shown below.

Compute $\Delta C_{L_{WS}}$ for the inboard wing station (Configuration 3):

$$\ell_{SP} + x_{FWD} = \ell_{SP} + \frac{x_{FWD}}{c} c$$

$$= 91.2 + (-0.158)(121.5)$$

$$= 72.0 \text{ in.}$$

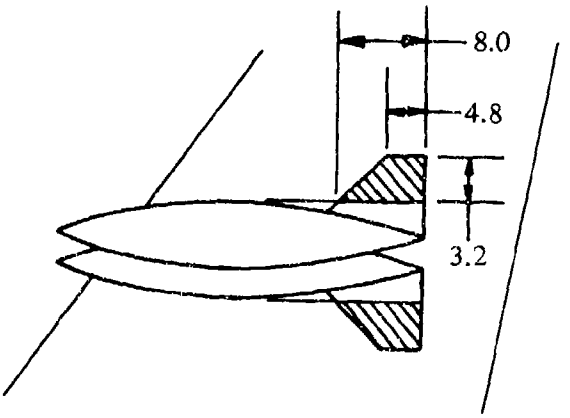
Since $x_{FWD} < 0$ and $c \geq \ell_{SP} + x_{FWD}$

$S_{W_{a_B}} = (\ell_{SP} + x_{FWD})d_w$ (Equation 3.1.1-f)

$= (72.0)(25.6)$

$= 1843 \text{ in.}^2$

To compute $S_{W_{a_F}}$, refer to the planform sketch below of the inboard wing installation:



$S_{W_{a_F}}$ is the shaded area of the fins not included in the $S_{W_{a_B}}$ computation.

$$S_{W_{a_F}} = (2)\left(\frac{8.0 + 4.8}{2}\right)(3.2)$$

$$= 41 \text{ in.}^2$$

$$S_{W_a} = 2\left(S_{W_{a_B}} + S_{W_{a_F}}\right) \qquad \text{(Equation 3.1.1-b)}$$

$$= 2\,(1843 + 41)$$

$$= 3768 \text{ in.}^2$$

$L_R = -4.7$ (Figure 3.1.1-14, Configuration 3)

$L_{LE} = 0\ (M \leqslant 0.8)$

$K_{AWA} = 0\ (M \leqslant 0.8)$

$K_A = 1.0$ (Figure 3.1.1-18a)

$K_H = -0.124$ (Figure 3.1.1-18b)

$K_X = 0.30$ (Figure 3.1.1-19a)

$$\frac{h_p}{d_w} = \frac{11.2}{25.6}$$

$$= 0.438$$

$K_W = 1.145$ (Figure 3.1.1-19b)

$K_P = 1 + K_H K_X K_W$ (Equation 3.1.1-i)

$= 1 + (-0.124)(0.30)(1.145)$

$= 0.957$

$K_{HF} = 0, \quad K_{VF} = 0$ (low-wing configuration)

$K_f = K_{HF} K_{VF} = 0$ (Equation 3.1.1-j)

$L_{\alpha_{WS}} = 0.43$ (Figure 3.1.1-21b)

Solution:

$$\Delta C_{L_{WS}} = \frac{1}{S_W}\left[(L_R + L_{LE}K_{AWA})(K_\Lambda K_p + K_f) + L_{\alpha_{WS}}(\alpha - 4.0)\right] \quad \text{(Equation 3.1.1-a)}$$

$$= \frac{1}{260}\left\{[-4.7 + (0)(0)]\,[(1.0)(0.957) + 0] + (0.43)(8.0 - 4.0)\right\}$$

$$= -0.0107 \text{ (inboard wing station)}$$

Compute $\Delta C_{L_{WS}}$ for the outboard wing station (Configuration 1):

$$\ell_{SP} + x_{FWD} = \ell_{SP} + \frac{x_{FWD}}{c}\,c$$

$$= 91.2 + (-0.264)(87.8)$$

$$= 68.0 \text{ in.}$$

Since $x_{FWD} < 0$ and $c \geq \ell_{SP} + x_{FWD}$

$$S_{W_{a_B}} = (\ell_{SP} + x_{FWD})d_w \quad \text{(Equation 3.1.1-f)}$$

$$= (68.0)(12.0)$$

$$= 816 \text{ in.}^2$$

As in the case of the inboard installation, trapezoidal areas of 2 fins extend beyond the projected store body area, $S_{W_{a_B}}$. Since the stores are identical,

$$S_{W_{a_F}} = 41 \text{ in.}^2 \text{ (previously calculated)}$$

$$S_{W_a} = 2\left(S_{W_{a_B}} + S_{W_{a_F}}\right) \quad \text{(Equation 3.1.1-b)}$$

$$= 2\,(816 + 41)$$

$$= 1714 \text{ in.}^2$$

$L_R = -0.8$ (Figure 3.1.1-12, Configuration 1)

$L_{LE} = 0$ (Configuration 1)

$K_{AWA} = 0$ (Applicable for multiple-rack carriage only)

$K_\Lambda = 1.0$ (Figure 3.1.1-18a)

$K_H = -0.124$ (Figure 3.1.1-18b)

$K_X = 0.68$ (Figure 3.1.1-19a)

$\frac{h_p}{d_w} = \frac{11.2}{12.0} = 0.93$

$K_W = 0.175$ (Figure 3.1.1-19b)

$K_p = 1 + K_H K_X K_W$ (Equation 3.1.1-i)

$= 1 + (-0.124)(0.68)(0.175)$

$= 0.985$

$K_{HF} = K_{VF} = 0$ (low-wing configuration)

$K_f = K_{HF} K_{VF} = 0$ (Equation 3.1.1-j)

$L_{\alpha_{WS}} = 0.40$ (Figure 3.1.1-21b)

Solution:

$$\Delta C_{L_{WS}} = \frac{1}{S_W}\left[(L_R + L_{LE} K_{AWA})(K_\Lambda K_p + K_f) + L_{\alpha_{WS}}(\alpha - 4.0)\right] \quad \text{(Equation 3.1.1-a)}$$

$$= \frac{1}{260}\left\{[-0.8 + (0)(0)]\,[(1.0)(0.985) + 0] + 0.40\,(8.0 - 4.0)\right\}$$

$$= 0.00312$$

The calculated values of $\Delta C_{L_{WS}}$ at each wing station are combined with fuselage-store increments in the sample problem of Section 3.1.3 to illustrate a complex loading configuration. Comparison of the calculated results with test data is provided in that section.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The user is cautioned that the accuracy of the method is less than that expected in the subsonic speed range, and test data should be used whenever possible.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range. The expected accuracy of the method is comparable to that in the subsonic range. The maximum Mach number provided in the design figures indicates the level to which the method is substantiated. Caution should be used when extrapolating the data beyond the Mach range provided in the figures.

3.1.2 LIFT INCREMENT DUE TO FUSELAGE-MOUNTED STORE INSTALLATIONS

A method is presented in this section for estimating the aircraft lift-coefficient increment due to fuselage-mounted store installations. The method as presented is for estimating the increment due to a pair of symmetric fuselage-mounted installations. The increment due to a single installation may also be obtained by using half the increment due to the pair of symmetric installations.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberance. The limitations on configuration and Mach-number range are summarized in Table 3.1-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The method has not been validated for pylon heights greater than 10 inches.

2. The method is limited to store installations which are not mounted beyond 90 percent of the fuselage semispan from the fuselage centerline.

3. The method has been verified for a Mach-number range between M = 0.6 and M = 2.0 with a few exceptions. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.

4. The method has not been verified for configurations in which flaps, slats or other flow-disrupting devices are deployed.

5. The method gives the best results for an angle-of-attack range from 0 to 8^{o}, although the method can be used for higher angles of attack.

6. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

7. No method is provided to estimate fuselage and adjacent-store interference effects. These effects may be significant if the separation distances are less than 3 store diameters. Proximity to engine inlets may also be significant.

8. The method is applicable for sideslip angles less than 4^{o}.

The loading configuration capabilities of the method are given in Table 3.1.2-A. Each configuration is assigned a number which is referred to throughout the method. The method is applied separately to each single store installation or symmetrical pair of store installations.

A. SUBSONIC

DATCOM METHOD

The incremental lift coefficient, based on wing reference area, due to a pair of symmetric fuselage-mounted external-store installations is given by Equation 3.1.2-a. (For a single installation, this value should be divided by two.)

$$\Delta C_{L_{FS}} = \frac{1}{S_W}\left[L_R K_{WING} K_{SPAN} + L_{\alpha_{FS}}(\alpha - 4.0)\right] \qquad 3.1.2\text{-a}$$

where

S_W is the wing reference area (ft^2).

L_R is an incremental-lift effect due to carriage-rack installation obtained from Figures 3.1.1-12 through 3.1.1-14 of Section 3.1.1 as a function of Mach number and S_{W_a}. (Refer to the discussion presented in Section 3.1.1 in relation to the Mach-number range and configuration applicability of this parameter.)

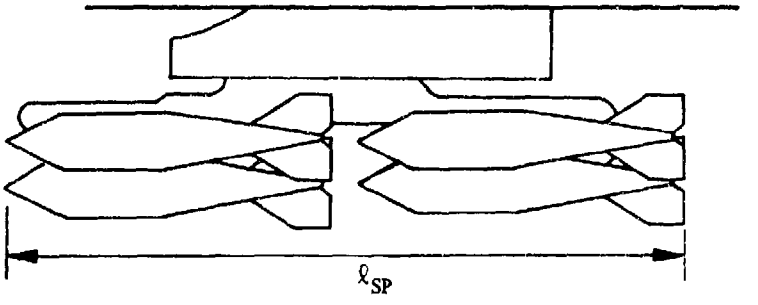
where, for fuselage-mounted installations

S_{W_a} is the pseudo store installation planform area ($in.^2$) for both installations, and is given by

$$S_{W_a} = 2\ell_{SP} d_w \qquad 3.1.2\text{-b}$$

where

ℓ_{SP} is the maximum store/pylon installation length (in.). (See Sketch (a).)



SKETCH (a)

d_w is the maximum width (in.) of the store installation not including protruding fins and is given by

1. For an empty pylon:

$$d_w = 1.5 \times \text{(maximum pylon width)} \qquad 3.1.2\text{-c}$$

2. For a single store:

$$d_w = d_S \qquad 3.1.2\text{-d}$$

(d_S is the maximum store diameter)

K_{WING} is a parameter to account for the effect of wing location on the fuselage. This parameter is obtained from Figure 3.1.2-6 as a function of z_w/h_f where

z_w is the distance from the top of the fuselage to the midpoint of the wing intersection with the fuselage (including canopy protuberances) (See Figure 3.1.2-6).

h_f is the overall height of the fuselage (including canopy protuberances) (See Figure 3.1.2-6).

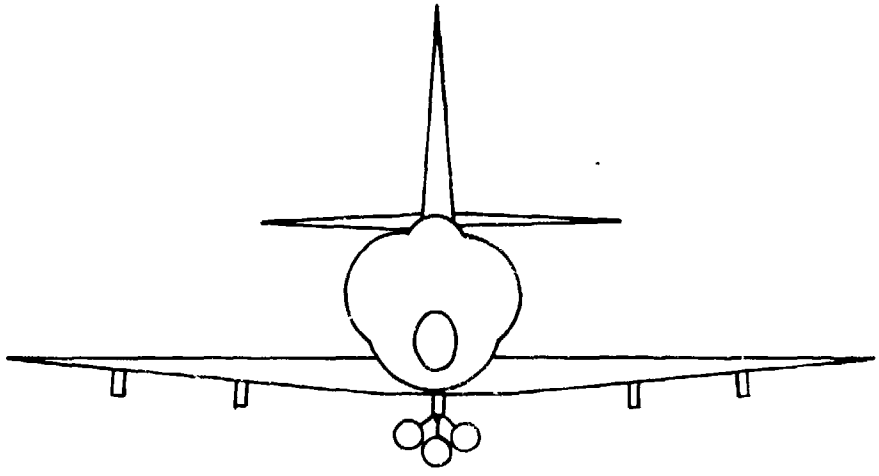
K_{SPAN} is a parameter to account for the effect of lateral placement of the store installation. The parameter is obtained from Figure 3.1.2-7 and is available for store installations mounted within 90% of the fuselage semispan from the fuselage centerline.

$L_{\alpha_{FS}}$ is an effect due to aircraft angle of attack obtained from Figure 3.1.2-8 as a function of aircraft wing location and Mach number.

α is the aircraft angle of attack (deg).

Sample Problem

Given: A swept-wing subsonic fighter aircraft (Reference 2) loaded with a pylon-mounted MER containing five 500-lb. bombs (two of the bombs are hidden in the front view) located below the fuselage centerline.



FRONT VIEW

Aircraft Data:

$S_W = 260\ ft^2$ $\qquad z_w/h_f = 0.88$

Stores Data:

$d_S = 12$ in.

Installation Data:

$d_w = 33.6$ in. $\qquad h_p = 11.2$ in. $\qquad \ell_{SP} = 185.6$ in.

Additional Data:

$M = 0.8$ $\qquad \alpha = 0^o$

It is noted from Table 3.1.2-A that this is Configuration Number 2. Since the loading is not a symmetrical pair of installations, the final result will be divided by 2 to obtain the increment for a single installation.

Compute:

$S_{W_a} = 2\ell_{SP} d_w$ (Equation 3.1.2-b)

$= (2)(185.6)(33.6)$

$= 12{,}472 \text{ in.}^2$

$L_R = -17.0$ (Figure 3.1.1-13, Configuration 2)

$z_w/h_f = 0.88$ (Given)

$K_{WING} = 0.93$ (Figure 3.1.2-6)

$K_{SPAN} = 1.0$ (Figure 3.1.2- 7)

$L_{\alpha_{FS}} = 0.15$ (Figure 3.1.2- 8)

Solution:

$$\Delta C_{L_{FS}} = \frac{1}{S_W}\left[L_R K_{WING} K_{SPAN} + L_{\alpha_{FS}}(\alpha - 4.0)\right] \quad \text{(Equation 3.1.2-a)}$$

$$= \frac{1}{260}[(-17.0)(0.93)(1.0) + (0.15)(8.0 - 4.0)]$$

$$= -0.0585 \quad \text{(symmetrical pair)}$$

For a single installation,

$$\Delta C_L = \frac{\Delta C_{L_{FS}}}{2} = \frac{-0.0585}{2} = -0.02925$$

The calculated value of $\Delta C_{L_{FS}}$ is combined with wing-store increments in the Sample Problem of Section 3.1.3 to illustrate a complex loading configuration. Comparison of the calculated results with test data is provided in that section.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid for transonic speeds. The user is cautioned that the accuracy of the method is less than that expected in the subsonic speed range; and test data should be used whenever possible.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid for supersonic speeds. The expected accuracy of the method is comparable to that in the subsonic range. The maximum Mach number provided in the design figures indicates the level to which the method is substantiated. Caution should be used when extrapolating the data beyond the Mach range provided in the figures.

3.1.3 TOTAL AIRCRAFT LIFT INCREMENT DUE TO EXTERNAL STORES

A method is presented in this section for estimating the total aircraft lift-coefficient increment due to external-store installations. The method predicts the increments for symmetric, asymmetric, and multiple-installation loading configurations.

The Datcom method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.1-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The method is not applicable to wing-tip or wing-tangent-mounted stores.

2. The method has not been validated for fuselage installations with pylon heights greater than 10 inches.

3. The method for fuselage-mounted stores is limited to installations which are not mounted beyond 90 percent of the fuselage semispan from the fuselage centerline.

4. The method has been verified for a Mach-number range between $M = 0.6$ and $M = 2.0$ with a few exceptions. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.

5. The method has not been verified for configurations in which flaps, slats or other flow-disrupting devices are deployed.

6. The method gives the best results for an angle-of-attack range from 0 to 8^{o}, although the method can be used for higher angles of attack.

7. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

8. No method is provided to estimate fuselage and adjacent-store interference effects. These effects may be significant if the separation distances are less than 3 store diameters. Proximity to engine inlets may also be significant.

9. The method is applicable for sideslip angles less than 4^{o}.

The procedure for computing the total lift-coefficient increment requires calculation of the increments for wing and fuselage installations separately by the methods of Sections 3.1.1 and 3.1.2, respectively. The increments for each installation are then summed to obtain the total increment.

A. SUBSONIC

DATCOM METHOD

The total aircraft lift-coefficient increment due to external-store installations and based on wing reference area, S_W, is given by

$$\Delta C_L = \sum_{i=0}^{N_{S_i}} (\Delta C_L)_i + \sum_{j=0}^{N_{A_j}} (\Delta C_L)_j \qquad 3.1.3\text{-a}$$

where

N_{S_i} is the total number of pairs of symmetrical external-store installations.

$(\Delta C_L)_i$ is the incremental lift coefficient due to a pair of symmetrical store installations where:

For wing-mounted installations

$$(\Delta C_L)_i = \Delta C_{L_{WS}} \qquad 3.1.3\text{-b}$$

and $\Delta C_{L_{WS}}$ is calculated in Section 3.1.1.

For fuselage-mounted installations

$$(\Delta C_L)_i = \Delta C_{L_{FS}} \qquad 3.1.3\text{-c}$$

and $\Delta C_{L_{FS}}$ is calculated in Section 3.1.2.

N_{A_i} is the total number of asymmetrical external-store installations.

$(\Delta C_L)_j$ is the incremental lift coefficient due to an asymmetric store installation where:

For wing-mounted installations,

$$(\Delta C_L)_j = \frac{1}{2} \Delta C_{L_{WS}} \qquad 3.1.3\text{-d}$$

and $\Delta C_{L_{WS}}$ is calculated in Section 3.1.1.

For fuselage-mounted installations

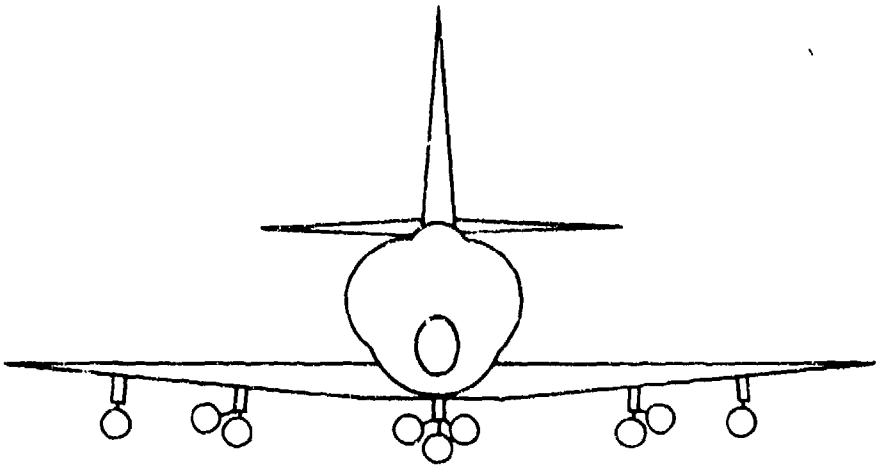
$$(\Delta C_L)_j = \frac{1}{2} \Delta C_{L_{FS}} \qquad 3.1.3\text{-e}$$

and $\Delta C_{L_{FS}}$ is calculated in Section 3.1.2.

Reference 1 states that prediction errors for incremental lift are nominally 20 percent. This generally results in an overall accuracy within 2 percent of total aircraft lift. Comparisons of test and calculated results are presented in Reference 1.

Sample Problem

Given: A swept-wing subsonic fighter aircraft from Reference 2, loaded as follows: (This is a combination of the configuration of the Sample Problems from Sections 3.1.1 and 3.1.2.)



FRONT VIEW

Spanwise Station	Rack Type	Mounting	Store Type	No. of Stores	Configuration Number
Centerline	MER	Pylon	500-lb Bomb	5	2
Inboard Wing	TER	Pylon	500-lb Bomb	2	3
Outboard Wing	Single	Pylon	500-lb Bomb	1	1

Additional Characteristics:

$M = 0.8$ $\alpha = 8^{O}$

(Additional geometric data are provided in the Sample Problems of Sections 3.1.1 and 3.1.2.)

Compute:

$N_{S_i} = 2$ (inboard- and outboard-wing installations)

$N_{A_i} = 1$ (centerline installation)

$(\Delta C_L)_i$ for i = 1,2:

$(\Delta C_L)_1 = \Delta C_{L_{WS}}$ (Equation 3.1.3-b)

where $\Delta C_{L_{WS}}$ is evaluated at the outboard-wing station and computed in the Sample Problem of Section 3.1.1.

$(\Delta C_L) = \Delta C_{L_{WS}} = 0.00312$

$(\Delta C_L)_2 = \Delta C_{L_{WS}}$ (Equation 3.1.3-b)

where $\Delta C_{L_{WS}}$ is evaluated at the inboard-wing station and computed in the Sample Problem of Section 3.1.1.

$(\Delta C_L)_2 = \Delta C_{L_{WS}} = -0.0107$

$(\Delta C_L)_j$ for j = 1:

$(\Delta C_L)_1 = \frac{1}{2}\Delta C_{L_{FS}}$ (Equation 3.1.3-e)

where $\Delta C_{L_{FS}}$ is evaluated at the fuselage-centerline station and computed in the Sample Problem of Section 3.1.2.

$(\Delta C_L)_1 = \Delta C_{L_{FS}} = -0.02925$

Solution:

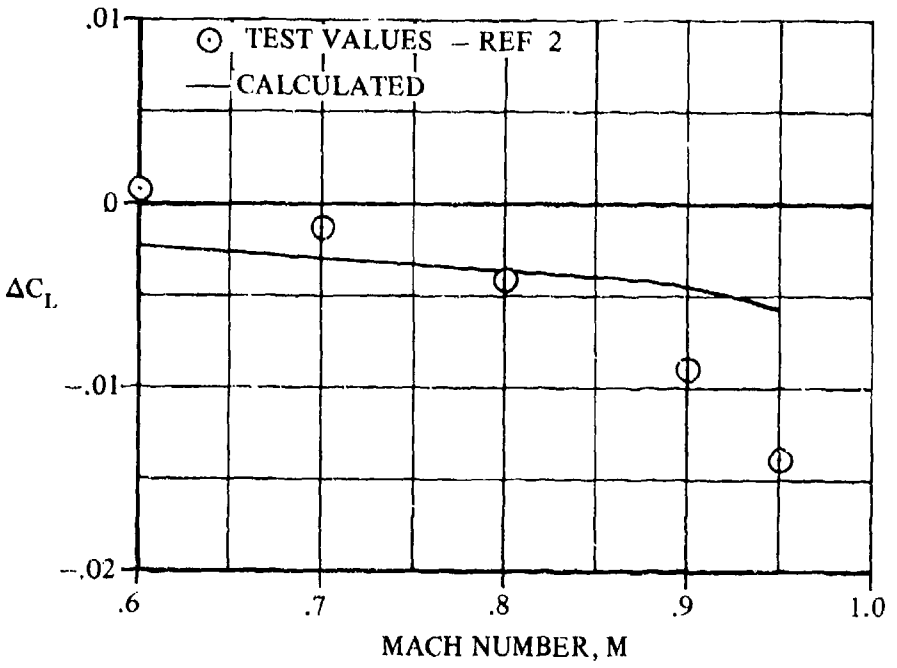
$$\Delta C_L = \sum_{i=0}^{N_{S_i}} (\Delta C_L)_i + \sum_{j=0}^{N_{A_i}} (\Delta C_L)_j \qquad \text{(Equation 3.1.3-a)}$$

$$\Delta C_L = \sum_{i=0}^{2} (\Delta C_L)_i + \sum_{j=0}^{1} (\Delta C_L)_j$$

$$= 0.00312 - 0.0107 - 0.02925$$

$$= -0.0368$$

Calculated results at additional Mach numbers are shown in comparison to test data from Reference 2 in Sketch (a).



SKETCH (a)

B. TRANSONIC

The method presented in Paragraph A of this section is also valid for transonic speeds. The user is cautioned that the accuracy of the method is less than that expected in the subsonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid for the supersonic speed range. The maximum Mach number provided in the design figures indicates the level to which the method is substantiated.

3.2 EFFECT OF EXTERNAL STORES ON AIRCRAFT DRAG

Methods are presented in this section for estimating the change in aircraft drag due to external-store installations. The methods predict an incremental change in drag coefficient, based on wing reference area, which can be added to the clean-aircraft drag coefficient to obtain the aircraft-with-stores drag coefficient. These methods are taken from Reference 1 and are empirical in nature.

Section 3.2 is subdivided as follows:

The total drag increment is the sum of the incremental drag at zero lift and the incremental drag due to lift. These components are computed in terms of equivalent-parasite-drag area for each installation by the methods of Sections 3.2.1 and 3.2.2 and are combined to obtain the total-drag-coefficient increment by the method of Section 3.2.3.

The Datcom methods are applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The methods are limited to the store-loading configurations and Mach-number ranges presented in Table 3.2-A. The methods are applicable to mixed loading configurations obtained by combining two or more loadings specified in Table 3.2-A. Additional limitations are specifically noted in each of the sections that follow.

TABLE 3.2-A

LOADING AND MACH-NUMBER LIMITATIONS

Mounting Location	Carriage Mode	Mount/Loading Type	Mach-Number Range
Wing	Single	Pylon – Empty	0.6 → 2.0
		Pylon – Single Store	
	Multiple	Pylon – Empty MER	0.6 → 1.6
		Pylon – Fully Loaded MER	
		Pylon – Partially Loaded MER	
		Pylon – Empty TER	
		Pylon – Fully Loaded TER	
		Pylon – Partially Loaded TER	
Fuselage	Single	Tangent – One Store	0.6 → 1.6
		Tangent – Two or More Stores	0.6 → 0.9
		Pylon – Empty	0.6 → 2.0
		Pylon – One Store	0.6 → 1.6
		Pylon – Two or More Stores	0.6 → 0.9
	Multiple	Tangent – One Store Installation	0.6 → 1.6
		Pylon – One Store Installation	
Wing or Fuselage		Adjacent Store Installation Interference	0.6 → 1.2
		Additional Drag Due to Lift	0.6 → 1.6

3.2.1 DRAG AT ZERO LIFT

3.2.1.1 BASIC DRAG DUE TO STORE INSTALLATIONS

Methods are presented in this section for estimating the zero-lift equivalent-parasite-drag area due to a store installation. This drag component does not include adjacent-store and fuselage interference effects (see Sections 3.2.1.2 and 3.2.1.3). The Datcom methods are presented for a particular store installation type and loading configuration, and are applied separately to each installation (armament station).

The methods are taken from Reference 1 and are empirical in nature. The methods are applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.2-A. Additional limitations and assumptions pertaining to the methods are listed below; however, some additional limitations pertaining to a specific method are given in the method descriptions.

1. The empirical design curves used in the methods generally do not provide data below $M = 0.6$, although the methods have been verified for some cases below this speed. Caution should be used when extrapolating the curves beyond the given Mach range.

2. The methods are not applicable to wing-tip and wing-tangent-mounted stores.

3. The methods have not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

4. The angle-of-attack range is from zero to cruise angle of attack.

5. The data base used in deriving the methods relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

6. The methods are applicable for sideslip angles less than 4°.

Methods are presented for the following particular store installation type and loading configurations:

Wing-Mounted Empty Pylon
Wing-Pylon-Mounted Single Store
Wing-Pylon-Mounted Empty MER
Wing-Pylon-Mounted Fully Loaded MER
Wing-Pylon-Mounted Partially Loaded MER
Wing-Pylon-Mounted Empty TER
Wing-Pylon-Mounted Fully Loaded TER
Wing-Pylon-Mounted Partially Loaded TER
Fuselage-Tangent-Mounted Stores (Two or More Single Stores)
Fuselage-Mounted Empty Pylon
Fuselage-Pylon-Mounted Stores (Two or More Single Stores)
Fuselage-Tangent-Mounted Single Store (One Installation)
Fuselage-Tangent-Mounted MER (One Installation)
Fuselage-Pylon-Mounted Single Store (One Installation)
Fuselage-Pylon-Mounted MER (One Installation)

A. SUBSONIC

DATCOM METHODS

The Datcom user should proceed directly to the method appropriate to the particular store installation type and loading configuration of interest.

Wing-Mounted Empty Pylon

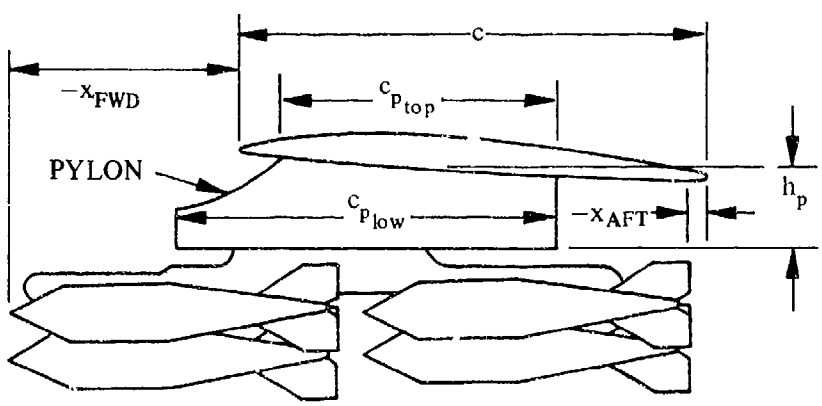
The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = \left(B_{xx} + K_{xx}\frac{S_P}{144}\right)\left[K_{CJK}\frac{t_{p_{max}}}{0.04}\left(\frac{2}{c_{p_{top}} + c_{p_{low}}}\right)(0.35 + 0.2167R_U)\right] + D_{PR} \qquad 3.2.1.1\text{-a}$$

where

B_{xx} is an empty-pylon drag factor obtained from Figure 3.2.1.1-20 as a function of Mach number and S_p, the pylon frontal area obtained by measuring the maximum cross-sectional area of the isolated pylon.

K_{xx} is an empty-pylon correlation ratio obtained from Figure 3.2.1.1-21a as a function of Mach number and x_{AFT}/c. The value of x_{AFT} is the longitudinal distance (in.) from the local wing trailing edge to the trailing edge of the store installation (or pylon trailing edge for the empty-pylon case), positive in the aft direction. (See Sketch (a).) The value of c is the local wing chord (in.) at the particular store or pylon station. (See Sketch (a).)



SKETCH (a)

K_{CJK} is a pylon Mach-number correlation parameter obtained from Figure 3.2.1.1-21b as a function of Mach number.

$t_{p_{max}}$ is the maximum pylon thickness (in.).

$c_{p_{top}}$ is the pylon-top-chord length (in.) at the wing-pylon juncture. (See Sketch (a).)

$c_{p_{low}}$ is the pylon-bottom chord length (in.). (See Sketch (a).)

R_U is a pylon-underside-roughness factor given by

R_U = 3, for the pylon-underside case (typical of wind-tunnel model) or for loaded pylons.

R_U = 4, for a rough-pylon-underside case (typical of full-scale hardware). } 3.2.1.1-b

R_U = 5, for an extremely rough-pylon-underside case, i.e., containing large cavities.

D_{PR} is the pylon-rack equivalent-parasite-drag area (ft^2) given by Figure 3.2.1.1.-22a as a function of Mach number.

Wing-Pylon-Mounted Single Store

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by separate equations at discrete Mach numbers. To obtain values at intermediate Mach numbers, interpolation must be used.

For M = 0.6:

$$D_B = B + \delta \qquad 3.2.1.1\text{-c}$$

where

B is the equivalent-parasite-drag area (ft^2) computed at M = 0.90 and given by

$$B = D_{ILP} + D_{IS} + D_I \qquad 3.2.1.1\text{-d}$$

where

D_{ILP} is the equivalent-parasite-drag area (ft^2) of the installed loaded pylon given by D_B in Equation 3.2.1.1-a evaluated at M = 0.90 and R_U = 3.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.90, given by

$$D_{IS} = S_\pi C_{D_\pi} \qquad 3.2.1.1\text{-e}$$

where

S_π is the store maximum cross-sectional area (ft^2).

C_{D_π} is the isolated-store drag coefficient at zero lift based on store maximum cross-sectional area. This term can be provided by the user, or can be estimated by using Section 4.2.3.1.

D_I is the equivalent-parasite-drag area (ft^2) due to pylon-store-aircraft interference at M = 0.90, given by

$$D_I = D_X + U_{\bar{y}} V_{\bar{x}} + E_u(22.6 - h_p) \qquad 3.2.1.1\text{-f}$$

where

D_X is the equivalent-parasite-drag area (ft^2) due to store-to-aircraft interference given by Figure 3.2.1.1-22b as a function of x_{AFT}/c, where x_{AFT} and c were previously defined for the wing-mounted empty-pylon case.

$U_{\bar{y}}$ is a lateral drag interference factor (ft) obtained from Figure 3.2.1.1-23a as a function of $\bar{y}$, the fraction of wing semispan location of the store station measured from the aircraft centerline.

$V_{\bar{x}}$ is a longitudinal drag interference factor (ft) obtained from Figure 3.2.1.1-23b as a function of x_{AFT}/c.

E_u is a pylon-height interference factor (ft^2/in.) obtained from Figure 3.2.1.1-23c as a function of x_{AFT}/c.

h_p is the average pylon height (in.). (See Sketch (a).)

δ is the equivalent-parasite-drag area (ft^2) obtained from Figure 3.2.1.1-24 as a function of B.

For M = 0.8:

$$D_B = B + 0.8\delta \qquad 3.2.1.1\text{-g}$$

where B and δ were defined previously.

For M = 0.9:

$$D_B = B \qquad 3.2.1.1\text{-h}$$

where B is given by Equation 3.2.1.1-d.

For M > 0.9, see Paragraphs B and C of this section.

Wing-Pylon-Mounted Empty MER

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = D_{ILP} + D_{MSB} + D_{IMR} \qquad 3.2.1.1\text{-i}$$

where

D_{ILP} is defined in the Wing-Pylon-Mounted Single-Store Case.

D_{MSB} is the MER sway-brace equivalent-parasite-drag area (ft^2) obtained from Figure 3.2.1.1-25 as a function of Mach number.

D_{IMR} is the installed-MER equivalent-parasite-drag area (ft^2) given by

$$D_{IMR} = R_{F_M} + R_{A_M} \qquad 3.2.1.1\text{-j}$$

where

R_{F_M} is a MER forward-longitudinal-placement term (ft^2) obtained from Figure 3.2.1.1-26 as a function of x_{FWD}/c and Mach number, where x_{FWD} is the distance from the local wing leading edge to the store/pylon nose (in.), positive for store nose aft of the local wing leading edge. (See Sketch (a).) The value of c is the local wing chord (in.) at the particular store or pylon station. (See Sketch (a).)

R_{A_M} is a MER aft-longitudinal-placement term (ft^2) obtained from Figure 3.2.1.1-27 as a function of x_{AFT}/c and Mach number, where x_{AFT} was previously defined for a Wing-Mounted Empty-Pylon Case. (See Sketch (a).)

Wing-Pylon-Mounted Fully Loaded MER

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = D_{EM} + 6D_{IS} + D_{IM} \qquad 3.2.1.1\text{-k}$$

where

D_{EM} is the empty-MER equivalent-parasite-drag area (ft^2) given by D_B from Equation 3.2.1.1-i.

D_{IS} is the isolated-store equivalent-parasite-drag area at M = 0.9. (See Equation 3.2.1.1-e.)

D_{IM} is the equivalent-parasite-drag area (ft^2) due to store-MER-aircraft interference, given by

$$D_{IM} = M_{I_S}\left(\frac{z_e^{\,2}\, d_w}{144c} - 30\right) + M_{I_I} \qquad 3.2.1.1\text{-}\ell$$

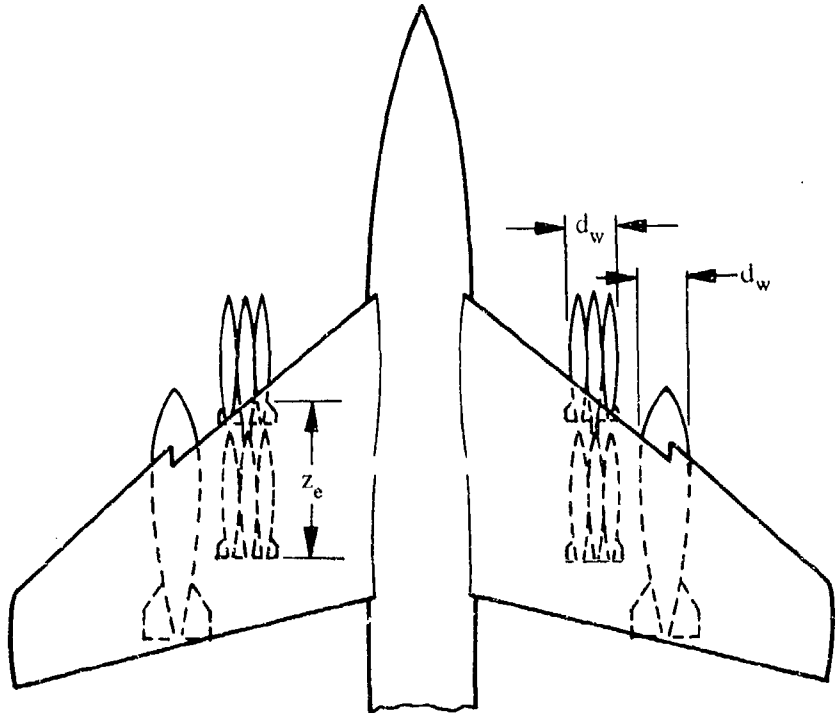
where

M_{I_S} is a store-MER-aircraft-interference Mach-correlation factor obtained from Figure 3.2.1.1-28 as a function of Mach number.

z_e is the vertically projected length of the store installation on the aircraft wing (in.). (See Sketch (b).)

d_w is the maximum width of the store installation (in.) not including protruding fins. (See Sketch (b).)

c is the local wing chord (in.) at the particular store or pylon station. (See Sketch (a).)



SKETCH (b)

M_{I_I} is a MER adjacent-store separation factor (ft^2) obtained from Figure 3.2.1.1-29 as a function of Mach number and d_c/d_S, where

d_c is the minimum clearance between adjacent stores. (See Figure 3.2.1.1-29.)

d_S is the maximum store diameter.

Wing-Pylon-Mounted Partially Loaded MER

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = D_{EM}\left(1 - \frac{N_{S_M} T_F}{6}\right) + D_{FLM} \qquad 3.2.1.1\text{-m}$$

where

D_{EM} was defined in the Wing-Pylon-Mounted Fully Loaded MER Case.

N_{S_M} is the total number of stores attached to the MER.

T_F is the tandem-stores factor given by

$$\left.\begin{aligned} T_F &= 1.00 \text{ for } N_{S_M} = 1, 5 \text{ or } 6 \text{ stores} \\ &= 1.00 \text{ for } N_{S_M} = 4 \text{ stores total with one store in tandem} \\ &= 0.90 \text{ for } N_{S_M} = 4 \text{ stores total with two stores in tandem} \\ &= 1.0 \text{ for } N_{S_M} = 3 \text{ stores total with one store in tandem} \\ &= 1.10 \text{ for } N_{S_M} = 3 \text{ stores total with none in tandem} \\ &= 0.90 \text{ for } N_{S_M} = 2 \text{ stores total with one store in tandem} \\ &= 1.10 \text{ for } N_{S_M} = 2 \text{ stores total with none in tandem} \end{aligned}\right\} \quad 3.2.1.1\text{-n}$$

D_{FLM} is the zero-lift equivalent-parasite-drag area (ft^2) due to a fully loaded MER given by D_B in Equation 3.2.1.1-k.

Wing-Pylon-Mounted Empty TER

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = D_{ILP} + D_{TSB} + D_{ITR} \qquad 3.2.1.1\text{-o}$$

where

D_{ILP} is defined in the Wing-Pylon-Mounted Single-Store Case.

D_{TSB} is the TER sway-brace equivalent-parasite-drag area (ft^2) obtained from Figure 3.2.1.1-30 as a function of Mach number.

D_{ITR} is the installed-TER equivalent-parasite-drag area (ft^2) given by

$$D_{ITR} = R_{F_T} + R_{A_T} \qquad 3.2.1.1\text{-p}$$

where

R_{F_T} is a TER forward-longitudinal-placement term (ft^2) obtained from Figure 3.2.1.1-31 as a function of x_{FWD}/c and Mach number, where x_{FWD} and c was previously defined for a Wing-Pylon-Mounted Empty-MER Case.

R_{A_T} is a TER aft-longitudinal-placement term (ft^2) obtained from Figure 3.2.1.1-32 (ft^2) as a function of x_{AFT}/c and Mach number, where x_{AFT} was previously defined for a Wing-Mounted Empty-Pylon Case.

Wing-Pylon-Mounted Fully Loaded TER

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = D_{ET} + 3D_{IS} + D_{IT} \qquad 3.2.1.1\text{-q}$$

where

D_{ET} is the empty-TER equivalent-parasite-drag area (ft^2) given by D_B from Equation 3.2.1.1-o.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

D_{IT} is the equivalent-parasite-drag area (ft^2) due to store-TER-aircraft interference given by

$$D_{IT} = T_{I_S}\left(\frac{z_e^2 d_w}{144c} - 10\right) + T_{I_I} \qquad 3.2.1.1\text{-r}$$

where:

T_{I_S} is a store-TER-aircraft-interference Mach-correlation factor obtained from Figure 3.2.1.1-33 as a function of Mach number.

z_e, d_w and c were previously defined in the Wing-Pylon-Mounted Fully-Loaded-MER Case.

T_{I_I} is a TER adjacent-store separation factor (ft^2) obtained from Figure 3.2.1.1-34 as a function of Mach number and d_c/d_s where d_c and d_s are defined in the Wing-Pylon-Mounted Fully-Loaded-MER Case.

Wing-Pylon-Mounted Partially Loaded TER

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by:

$$D_B = D_{ET}\left(1 - \frac{N_{S_T}}{3}\right) + D_{FLT} \qquad 3.2.1.1\text{-s}$$

where

D_{ET} is the empty-TER equivalent-parasite-drag area (ft^2) given by D_B from Equation 3.2.1.1-o.

N_{S_T} is the number of stores attached to the TER.

D_{FLT} is the zero-lift equivalent-parasite-drag area (ft^2) due to a fully loaded TER given by D_B in Equation 3.2.1.1-q.

Fuselage-Tangent-Mounted Stores
(Two or More Single Stores)

The Datcom Method for this configuration is applicable only for 2 or 3 store-row installations mounted on the fuselage bottom surface, and for a Mach-number range of from 0.6 to 0.9. The following additional limitations apply:

1. Same number of stores per row for two- or three-row configurations.
2. Constant fuselage-station location for all stores on a given row.
3. Constant longitudinal space between all stores in tandem, for two- or three-row configurations.
4. Constant lateral space between all stores.
5. Coincident store centerlines for stores in tandem (maximum number of stores in tandem = 3; maximum number of stores/row = 5; staggered store arrangements not included).
6. Effective store-diameter range: 8.0 to 11.5 inches.
7. All stores in one installation must be identical.

Due to the nature of this method, the zero-lift equivalent-parasite-drag area, D_B, is computed for all stores taken together. In order to be consistent with the values of D_B computed by other methods in this section, the entire group of stores is considered to be *one* installation.

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by:

$$D_B = n_r D_{FR} + D_{IS} K_{NI} \qquad 3.2.1.1\text{-t}$$

where

n_r is the number of stores per row.

D_{FR} is the fuselage-rack equivalent-parasite-drag area and is a function of the number of rows of stores mounted on the fuselage:

$$D_{FR} = a_1 b_1 \text{ (1 row)} \qquad 3.2.1.1\text{-u}$$

$$D_{FR} = a_1 b_1 + a_2 b_2 \text{ (2 rows)} \qquad 3.2.1.1\text{-v}$$

$$D_{FR} = a_1 b_1 + a_2 b_2 + a_3 b_3 \text{ (3 rows)} \qquad 3.2.1.1\text{-w}$$

where

a_1, a_2, and a_3 are store-diameter correlation factors obtained from Figure 3.2.1.1-35 as a function of the maximum store diameter d_s.

b_1, b_2, and b_3 are store-row Mach-correlation factors obtained from Figure 3.2.1.1-36 as a function of Mach number.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

K_{NI} is a planform and store-location factor given by

$$K_{NI} = K_{D_1} K_{D_2} K_{D_3} K_{D_4} K_{D_5} K_{D_6} K_{D_7} \qquad 3.2.1.1\text{-x}$$

where

K_{D_1} is a store frontal-area factor given by

$$K_{D_1} = K_{S_M} \left(1 + \frac{3S_\pi}{S_B}\right) \qquad 3.2.1.1\text{-y}$$

where

K_{S_M} is a Mach-effect factor for K_{D_1} obtained from Figure 3.2.1.1-37a as a function of Mach number.

S_π is the store maximum cross-sectional area (ft^2).

S_B is the maximum-fuselage frontal area (ft^2).

K_{D_2} is the wing-sweep-and-location factor obtained from Figure 3.2.1.1-37b as a function of wing leading-edge sweep, wing location, and Mach number.

K_{D_3} is a tandem-spacing factor obtained from Figure 3.2.1.1-38a as a function of Mach number and X_{OL}, the ratio of longitudinal spacing between tandem stores to the store length.

K_{D_4} is a lateral-spacing factor obtained from Figure 3.2.1.1-38b as a function of Y_{OD}, the ratio of the minimum lateral distance (excluding fins) between stores to the maximum store diameter.

K_{D_5} and K_{D_6} are store-rows and stores-per-row correlation factors respectively, obtained by using Table 3.2.1.1-A.

TABLE 3.2.1.1-A

K_{D_5} AND K_{D_6} COMPUTATION

Correlation Factor	No. of Store Rows or Stores Per Row	Figure No. or Value
K_{D_5}	1	Figure 3.2.1.1-39a
	2	Figure 3.2.1.1-39b
	3	1.0
K_{D_6}	1	Figure 3.2.1.1-40
	2	Figure 3.2.1.1-41a
	3	Figure 3.2.1.1-41b

It should be noted that K_{D_5} for the case of 3 store rows is only substantiated for $0.6 \leq M \leq 0.9$.

K_{D_7} is a store longitudinal-location factor obtained from Figure 3.2.1.1-42a as a function of Mach number and x_r, the ratio of the distance between the aircraft nose and the store nose of the most forward store to the aircraft-fuselage length

Fuselage-Mounted Empty Pylon

The Datcom Method for this configuration is applicable for a pylon-frontal-area range of from 20 to 170 square inches, and only for pylons mounted on the bottom surface of the fuselage. The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = B_{xx}\left[K_{CJK}\frac{t_{p_{max}}}{0.04}\left(\frac{2}{c_{p_{top}} + c_{p_{low}}}\right)(0.35 + 0.2167R_U)\right] \qquad 3.2.1.1\text{-z}$$

where all of the above terms are defined in the Wing-Mounted-Empty-Pylon Case.

Fuselage-Pylon-Mounted Stores
(Two or More Single Stores)

The Datcom Method for this configuration is subject to the same limitations given for the Fuselage-Tangent-Mounted Stores Case. Due to the nature of the method, the zero-lift equivalent-parasite-drag area, D_B, is computed for all stores taken together. In order to be consistent with the values of D_B computed by other methods in this section, the entire group of stores is considered to be *one* installation. The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = n_P D_{LPF} + n_r D_{FR} + K_{SD} K_{PD} K_{NI} D_{IS} \qquad 3.2.1.1\text{-aa}$$

where

n_P is the number of pylons.

D_{LPF} is the zero-lift equivalent-parasite-drag area (ft^2) due to the fuselage-mounted empty pylon given by D_B in Equation 3.2.1.1-z with $R_U = 3.0$.

n_r is the number of stores per row.

D_{FR} is the fuselage-rack equivalent-parasite-drag-area (ft^2) contribution given by Equations 3.2.1.1-u, v, w.

K_{SD} is a store-depth factor obtained from Figure 3.2.1.1-42b as a function of Mach number and X_{OL}, the ratio of longitudinal spacing between tandem stores to the store length.

K_{PD} is a pylon-depth factor obtained from Figures 3.2.1.1-43a through -43o as a function of Mach number, number of rows, number of stores per row, and H_{OD} where

$$H_{OD} = \frac{h_p + 1.5}{d_S} \qquad \text{3.2.1.1-bb}$$

where

h_p is the average pylon height (in.).

d_S is the maximum store diameter (in.).

K_{NI} is a planform and store-location factor defined by Equation 3.2.1.1-x.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

Fuselage-Tangent-Mounted Single Store
(One Installation)

The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = (1 + K_{IF})(D_{PR} + D_{IS}) \qquad \text{3.2.1.1-cc}$$

where

K_{IF} is an installation factor obtained from Figures 3.2.1.1-51a through -51g for single stores, as a function of Mach number, fuselage bottom surface shape (bottom surface either curved or straight), the maximum depth of the store installation measured from the bottom surface of wing z (in.), and the average pylon height (in.) h_p.

D_{PR} is the pylon-rack equivalent-parasite-drag area (ft^2) given by Figure 3.2.1.1-22a as a function of Mach number.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

Fuselage-Tangent-Mounted MER
(One Installation)

The Datcom Method for this configuration is limited to a single MER installation tangent mounted on the bottom of the fuselage. The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = (1 + K_{IF})(D_{PR} + 6D_{IS} + D_{MSB} + D_{MRF}) \qquad 3.2.1.1\text{-dd}$$

where

K_{IF} is an installation factor for tangent-mounted stores obtained from Figures 3.2.1.1-54a through -54g for MER installations.

D_{PR} is the pylon-rack equivalent-parasite-drag area (ft^2) given by Figure 3.2.1.1-22a as a function of Mach number.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

D_{MSB} is the MER-sway-brace equivalent-parasite-drag area (ft^2) obtained from Figure 3.2.1.1-25 as a function of Mach number.

D_{MRF} is the zero-lift equivalent-parasite-drag area (ft^2) due to MER-rack-to-fuselage interference obtained from Figure 3.2.1.1-57 as a function of Mach number.

Fuselage-Pylon-Mounted Single Store
(One Installation)

The Datcom Method for this configuration is applicable for a pylon-frontal-area range of from 20 to 170 square inches, and only for pylons mounted on the bottom surface of the fuselage. The zero-lift equivalent-parasite-drag area (ft^2) due to the basic installation is given by

$$D_B = (1 + K_{IF})(D_{PR} + D_{IS} + D_{ILP}) \qquad 3.2.1.1\text{-ee}$$

where

K_{IF} is an installation factor as defined for the Fuselage-Tangent-Mounted Single-Store Case, obtained from Figures 3.2.1.1-51a through -51g.

D_{PR} is the pylon-rack equivalent-parasite-drag area (ft^2) given by Figure 3.2.1.1-22a as a function of Mach number.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

D_{ILP} is the equivalent-parasite-drag area (ft^2) of the installed loaded pylon given by D_B from Equation 3.2.1.1-z with $R_U = 3.0$.

Fuselage-Pylon-Mounted MER
(One Installation)

The Datcom Method for this configuration has the same limitations as the previous case. The zero-lift equivalent-parasite-drag area ( ) due to the basic store installation is given by

$$D_B = (1 + K_{IF})(D_{PR} + 6D_{IS} + D_{ILP} + D_{MRF} + D_{MSB}) \qquad 3.2.1.1\text{-ff}$$

where

K_{IF} is an installation factor as defined for the Fuselage-Tangent-Mounted MER Case, obtained from Figures 3.2.1.1-54a through 3.2.1.1-54g.

D_{PR} is the pylon-rack equivalent-parasite-drag area (ft^2) given by Figure 3.2.1.1-22a as a function of Mach number.

D_{IS} is the isolated-store equivalent-parasite-drag area (ft^2) at M = 0.9, given by Equation 3.2.1.1-e.

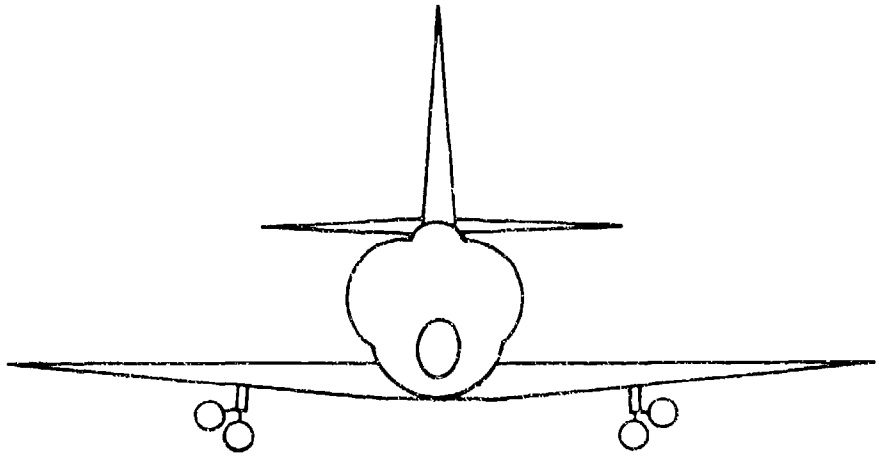
D_{ILP} is the installed-loaded-pylon equivalent-parasite-drag area (ft^2) given by D_B from Equation 3.2.1.1-z with $R_U = 3.0$.

D_{MRF} is the zero-lift equivalent-parasite-drag area (ft^2) due to MER-rack-to-fuselage interference obtained from Figure 3.2.1.1-57 as a function of Mach number.

D_{MSB} is the MER-sway-brace equivalent-parasite-drag area (ft^2) obtained from Figure 3.2.1.1-25 as a function of Mach number.

Sample Problem

Given: A swept-wing subsonic fighter aircraft (Reference 2) symmetrically loaded at the inboard wing stations with pylon-mounted TER's, each containing two 500-lb bombs.



FRONT VIEW

Aircraft Data: c = 121.5 in.

Store Data:

$S_\pi = 0.785\ ft^2$ $C_{D_\pi} = 0.11$ $d_S = 12$ in.

Installation Data:

$S_P = 51.3\ in.^2$ $t_{P_{max}} = 4.7$ in. $c_{P_{top}} = 66.9$ in. $c_{P_{low}} = 66.9$ in.

$x_{AFT} = -49.6$ in. $x_{FWD} = -10.4$ in. $d_c = 3.2$ in. $d_w = 25.6$ in.

$z_e = 70.4$ in.

Additional Data:

M = 0.6

Compute: (Method – Wing-Pylon-Mounted Partially Loaded TER)

Since the installation is symmetrical, only one side need be computed.

$$D_B = D_{ET}\left(1 - \frac{N_{S_T}}{3}\right) + D_{FLT} \qquad \text{(Equation 3.2.1.1-s)}$$

Expand the above equation to identify the terms which need to be computed:

$$D_{ET} = D_{ILP} + D_{TSB} + D_{ITR} \qquad \text{(Equation 3.2.1.1-o)}$$

$$D_{FLT} = D_{ET} + 3D_{IS} + D_{IT} \qquad \text{(Equation 3.2.1.1-q)}$$

Find D_{ILP}:

$$\frac{x_{AFT}}{c} = \frac{-49.6}{121.5} = -0.408$$

$B_{xx} = 0.106$ (Figure 3.2.1.1-20)

$K_{xx} = 0.16$ (Figure 3.2.1.1-21a)

$K_{CJK} = 0.25$ (Figure 3.2.1.1-21b)

$D_{PR} = 0.088\ ft^2$ (Figure 3.2.1.1-22a)

$$D_{ILP} = \left(B_{xx} + K_{xx}\frac{S_P}{144}\right)\left[K_{CJK}\frac{t_{p_{max}}}{0.04}\left(\frac{2}{c_{p_{top}} + c_{p_{low}}}\right)(0.35 + 0.2167R_U)\right] + D_{PR}$$

(Equation 3.2.1.1-a)

$$= \left[0.106 + (0.16)\left(\frac{51.3}{144}\right)\right]\left\{(0.25)\frac{(4.7)}{(0.04)}\frac{(2)[0.35 + (0.2167)3]}{(66.9 + 66.9)}\right\} + 0.088$$

$$= 0.160 \text{ ft}^2$$

Find D_{TSB}:

$D_{TSB} = 0.180 \text{ ft}^2$ (Figure 3.2.1.1-30)

Find D_{ITR}:

$$\frac{x_{FWD}}{c} = \frac{-10.4}{121.5} = -0.0856$$

$R_{F_T} = 0$ (Figure 3.2.1.1-31)

$R_{A_T} = 0.300$ (Figure 3.2.1.1-32)

$D_{ITR} = R_{F_T} + R_{A_T} = 0 + 0.300 = 0.300 \text{ ft}^2$ (Equation 3.2.1.1-p)

Find D_{ET}:

$D_{ET} = D_{ILP} + D_{TSB} + D_{ITR}$ (Equation 3.2.1.1-o)

$= 0.160 + 0.180 + 0.300$

$= 0.640 \text{ ft}^2$

Find D_{IS}:

$D_{IS} = S_\pi C_{D_\pi} = (0.785)(0.11)$ (Equation 3.2.1.1-e)

$= 0.0864 \text{ ft}^2$

Find D_{IT}:

$T_{IS} = 0.005$ (Figure 3.2.1.1-33)

$$\frac{d_c}{d_S} = \frac{3.2}{12} = 0.267$$

$T_{I_I} = 0.40$ (Figure 3.2.1.1-34)

$$D_{I_T} = T_{I_S}\left(\frac{z_e^{\,2}\, d_w}{144c} - 10\right) + T_{I_I} \quad \text{(Equation 3.2.1.1-r)}$$

$$= 0.005\left[\frac{(70.4)^2(25.6)}{(144)(121.5)} - 10\right] + 0.40$$

$$= 0.386 \text{ ft}^2$$

Find D_{FLT}:

$$D_{FLT} = D_{ET} + 3D_{IS} + D_{IT} \quad \text{(Equation 3.2.1.1-q)}$$

$$= 0.640 + (3)(0.0864) + 0.386$$

$$= 1.285 \text{ ft}^2$$

Solution:

$$D_B = D_{ET}\left(1 - \frac{N_{S_T}}{3}\right) + D_{FLT} \quad \text{(Equation 3.2.1.1-s)}$$

$$= 0.640\left(1 - \frac{2}{3}\right) + 1.285 = 1.498 \text{ ft}^2 \text{ (one side)}$$

This result is used in the Sample Problem of Paragraph A of Section 3.2.3 as part of the total-drag-increment computation.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid for transonic speeds with the exception of the following fuselage-mounted configurations which are limited to $M \leqslant 0.9$:

1. Two or more stores tangent-mounted in single-carriage modes.

2. Two or more stores pylon-mounted in single-carriage modes.

The method presented in Paragraph A for the Wing-Pylon-Mounted Single-Store Case requires additional equations in the transonic speed range. Separate equations for D_B are required at discrete Mach numbers as in the subsonic case. To obtain values at intermediate Mach numbers, interpolation must be used.

Wing-Pylon-Mounted Single Store

For M = 0.9:

$$D_B = B \qquad \text{(Equation 3.2.1.1-h)}$$

where

B is given by Equation 3.2.1.1-d.

For M = 0.95:

$$D_B = 0.77\,[(B + T_A S_\pi)P - B] + B \qquad 3.2.1.1\text{-gg}$$

where

B is given by Equation 3.2.1.1-d.

T_A is a transonic-supersonic correlation factor obtained from Figure 3.2.1.1-58a as a function of x_{FWD}, x_{AFT}, and c where

x_{FWD} is the longitudinal distance from the local wing leading edge to the store/pylon nose (in.), positive for store nose aft of the local wing leading edge. (See Sketch (a).)

x_{AFT} is the longitudinal distance (in.) from the local wing trailing edge to the trailing edge of the store installation (or pylon trailing edge for the empty pylon case), positive in the aft direction. (See Sketch (a).)

c is the local wing chord at the local store or pylon station (in.). (See Sketch (a).)

S_π is the maximum store cross-sectional area (ft^2).

P is a clean-aircraft drag-rise factor obtained from Figure 3.2.1.1-58b as a function of the clean-aircraft drag-rise factor, C'_{D_0}, where

$$C'_{D_0} = \frac{C_{D_0} \text{ at } M = 1.05}{C_{D_0} \text{ at } M = 0.6} \qquad 3.2.1.1\text{-hh}$$

where

C_{D_0} is the clean-aircraft zero-lift drag coefficient from test data or estimated from Section 4.5.3.1.

For M = 1.05:

$$D_B = (B + T_A S_\pi)P \qquad 3.2.1.1\text{-ii}$$

where B, T_A, S_π, and P are defined above.

For M = 1.20:

$$D_B = B + T_A S_\pi \qquad 3.2.1.1\text{-jj}$$

where B, T_A, and S_π are defined above.

The user is cautioned that the accuracy of the method is less than that of the subsonic speed range, and test data should be used whenever possible.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid for supersonic speeds within the Mach-number limits specified in Table 3.2-A. The method presented in Paragraph A for the Wing-Pylon-Mounted Single-Store Case requires the following modification in the supersonic speed range.

Wing-Pylon-Mounted Single Store

For M = 1.60 to M = 2.00:

D_B is obtained from Figures 3.2.1.1-59a and -59b as a function of $B + T_A S_\pi$.

The user should exercise caution in extrapolating the method beyond the specified Mach-number range.

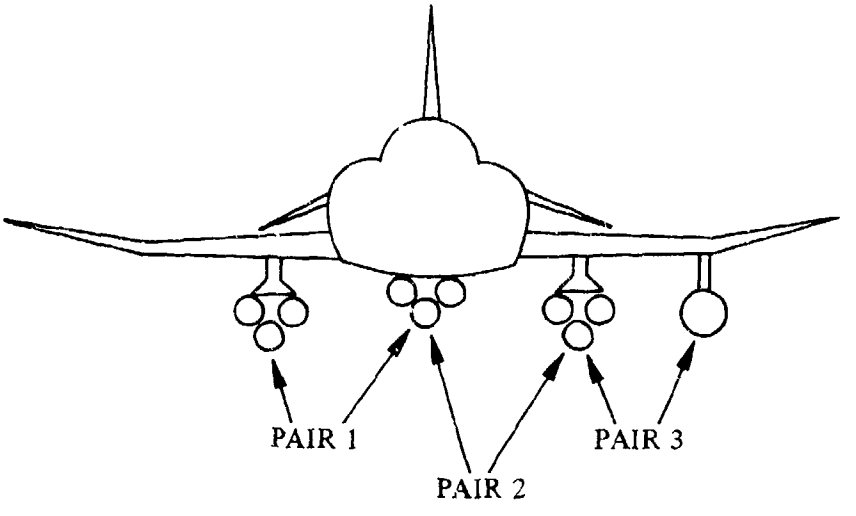
3.2.1.2 DRAG DUE TO ADJACENT STORE INTERFERENCE

A method is presented in this section for estimating the zero-lift equivalent-parasite-drag area due to the interference effects of a pair of adjacent store installations. When separate installations are mounted sufficiently close to each other, an interference effect on drag is produced which should be accounted for in the total drag estimate. This effect may be either positive or negative, depending upon the relative positions of the store installations. The effect is computed for each pair of adjacent installations on the aircraft. For example, the aircraft pictured in Sketch (a) would require three computations.



SKETCH (a)

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.2-A. Caution should be used when extrapolating the curves beyond the given Mach-number range. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

A. SUBSONIC

DATCOM METHOD

The zero-lift equivalent-parasite-drag area (ft^2) due to the mutual interference of adjacent store installations per pair of adjacent store installations is given by D_{I_S} where

D_{I_S} is obtained from Figures 3.2.1.2-4a through -4c as a function of Mach number, Y_S, d_{w_L}, d_{w_A}, T_N, and ℓ_{AFT}.

where these terms are illustrated in Sketch (b) and defined as

Y_S is the minimum lateral clearance (in.) between adjacent-store installations (store surface to store surface).

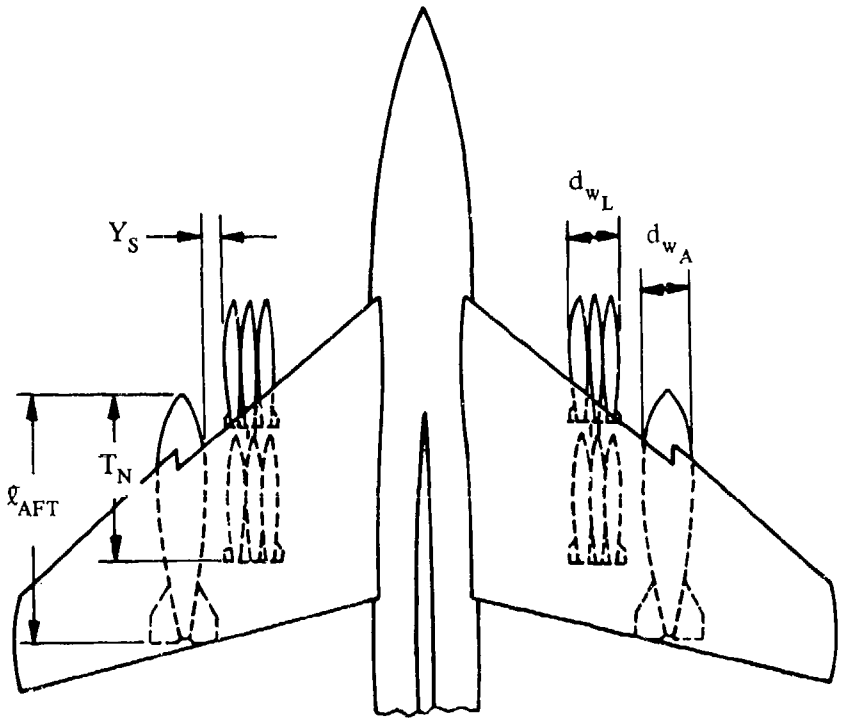
d_{w_L} is the maximum width (in.) of the lead- (most forward) store installation.

d_{w_A} is the maximum width (in.) of the aft-store installation.

T_N is the distance from the nose of the aft-store installation to the tail of the lead-store installation (in.)

ℓ_{AFT} is the length (in.) of the aft-store installation.

It is necessary to use interpolation for Mach numbers not presented in the figures.



SKETCH (b)

Sample Problem

Given: A swept-wing aircraft symmetrically loaded as shown in Sketch (b).

Stores Data:

Y_S = 10 in. d_{w_L} = 42 in. d_{w_A} = 40 in. T_N = 135 in. ℓ_{AFT} = 205 in.

Additional Data:

M = 0.7

Compute: Referring to Figures 3.2.1.2-4a through -4c, it can be seen that data are presented for M = 0.6, 0.9, and 1.2. It will, therefore, be necessary to obtain D_{I_S} at each of the three Mach numbers and interpolate to obtain the value at M = 0.7.

Compute the independent variables for Figures 3.2.1.2-4a through -4c:

$$\frac{Y_S}{d_{w_L} + d_{w_A}} = \frac{10}{42 + 40} = 0.122$$

$$\frac{T_N}{q_{AFT}} = \frac{135}{205} = 0.659$$

Solution:

At M = 0.6	$D_{I_S} = 0.075$ ft^2	(Figure 3.2.1.2-4a)
At M = 0.9	$D_{I_S} = 0.460$ ft^2	(Figure 3.2.1.2-4b)
At M = 1.2	$D_{I_S} = 0.265$ ft^2	(Figure 3.2.1.2-4c)

Interpolating the above three points at M = 0.7 yields $D_{I_S} = 0.230$ ft^2

B. TRANSONIC

The method presented in Paragraph A of this section is also applicable in the transonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is also applicable in the supersonic speed range. Although no design curves are presented beyond M = 1.2, the existing curves can be cross plotted and extrapolated to M = 1.6 with reasonable success.

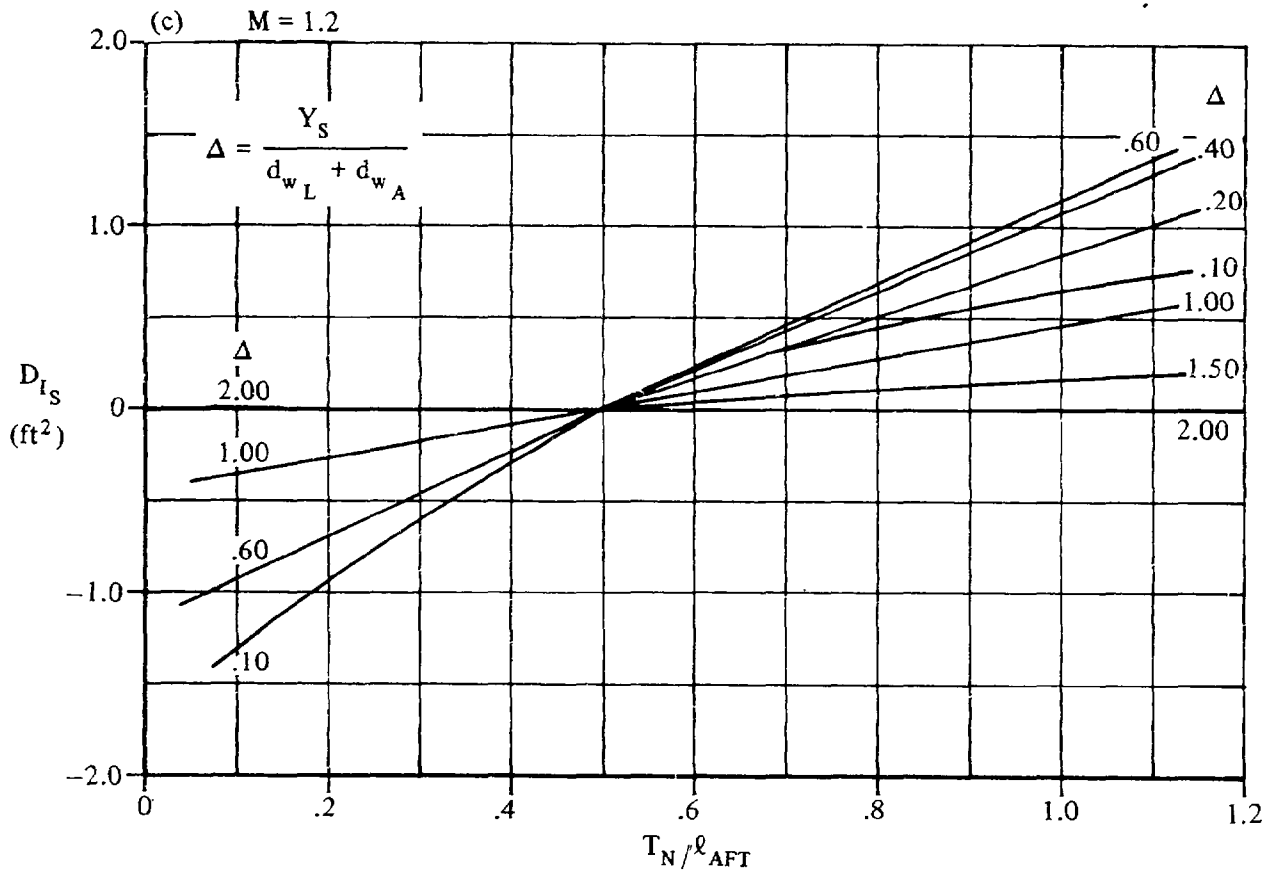

FIGURE 3.1.2-4 (CONTD)

3.2.1.3 DRAG DUE TO FUSELAGE INTERFERENCE

A method is presented in this section for estimating the zero-lift equivalent-parasite-drag area due to the mutual interference effect of a store installation and the adjacent fuselage. This effect is present for wing-mounted stores on high-wing aircraft which are mounted sufficiently close to the fuselage. The interference effect on low-wing aircraft is negligible.

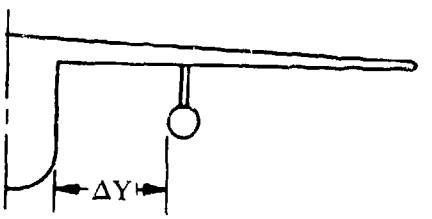
The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.2-A, with the following exception: The method is valid to a maximum Mach number of 0.95. The design curves should not be extrapolated to higher Mach numbers due to the uncertain nature of the interference effects. Caution should be used in extrapolating the curves below M = 0.6. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

A. SUBSONIC

DATCOM METHOD

The zero-lift equivalent-parasite-drag area (ft^2) due to the mutual interference of store installation and adjacent fuselage is given by D_{I_f} where D_{I_f} is obtained from Figure 3.2.1.3-3 as a function of Mach number and the minimum clearance between the store installation and the fuselage, ΔY (in.). (See Sketch (a).)

Note that $D_{I_f} = 0$ for low-wing aircraft.



SKETCH (a)

Sample Problem

Given: A high-wing aircraft with a pylon-mounted single store as shown in Sketch (a).

$M = 0.75$ $\Delta Y = 12$ in.

Solution:

$D_{I_f} = 0.290\ ft^2$ (Figure 3.2.1.3-3)

B. TRANSONIC

The method presented in Paragraph A of this section can be applied in the transonic speed range up to a Mach number of 0.95. Extrapolation of the data beyond this Mach number is not recommended due to the uncertain nature of the interference effects.

C. SUPERSONIC

No method is presented to estimate the fuselage-interference effect on drag in the supersonic speed range.

REFERENCE

1. Gallagher, R. D., Jimenez, G., Light, L. E., and Thames, F. C.: Technique for Predicting Aircraft Aerodynamic Effects Due to External Stores Carriage. AFFDL-TR-75-95, Volumes I and II, 1975. (U)

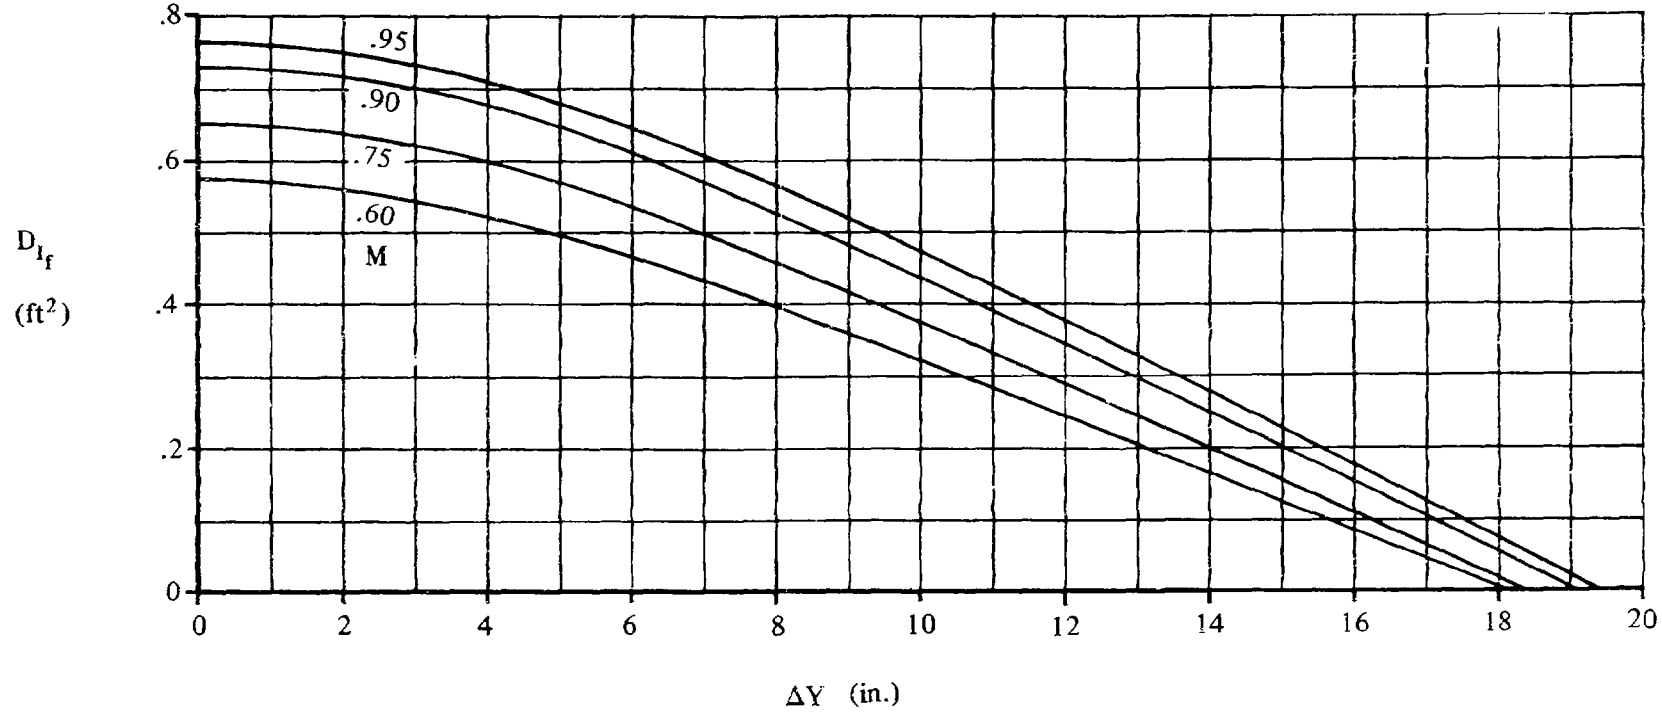


FIGURE 3.2.1.3-3 EQUIVALENT-PARASITE-DRAG AREA DUE TO MUTUAL INTERFERENCE OF STORE INSTALLATION AND ADJACENT FUSELAGE

3.2.2 DRAG DUE TO LIFT

A method is presented in this section for estimating the lift-induced equivalent-parasite-drag area due to an external-store installation. The method is applied separately to each installation (armament station). For all fuselage-mounted store installations, the equivalent-parasite-drag area due to lift is considered to be negligible.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.2-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The empirical design curves used in the method do not provide data below M = 0.6, although the method has been verified for some cases below this speed. Caution should be used when extrapolating the curves below the given Mach-number range.

2. The method is not applicable to wing-tip and wing-tangent-mounted stores.

3. The method has not been verified for configurations in which flaps, slats or other flow-disrupting devices are deployed.

4. The angle-of-attack is from zero to cruise angle of attack.

5. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

6. The method is applicable for sideslip angles less than 4°.

A. SUBSONIC

DATCOM METHOD

The store-installation drag due to lift is a function of aircraft lift coefficient, wing aspect ratio, and an empirical factor. This drag contribution is negative for all configurations for which the method is applicable. For wing-pylon-mounted-store installations, the equivalent-parasite-drag area (ft^2) due to lift is given by

$$D_i = 46.875\, C_L\, A_W\, R_i \qquad 3.2.2\text{-a}$$

where

C_L is the aircraft lift coefficient with store effects based on S_W. This term should be obtained from test data or can be estimated using Sections 3.1.3 and 4.5.1.1.

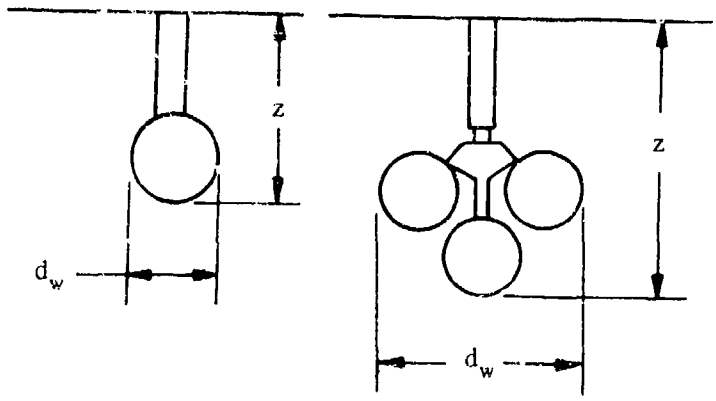
A_W is the wing aspect ratio, based on the total trapezoidal planform.

R_i is the normalized, incremental drag due to lift obtained from Figure 3.2.2-3 as a function of z, d_w, and Mach number where

z is the maximum depth of the store installation (in.). (See Sketch (a).)

d_w is the maximum width of the store installation (in.). (See Sketch (a).)

It is necessary to use interpolation for Mach numbers not presented in the figures.



SKETCH (a)

Sample Problem

Given: A swept-wing subsonic fighter aircraft (Reference 2) symmetrically loaded at the inboard-wing stations with pylon-mounted TER's, each containing two 500-lb bombs. This is the same configuration analyzed in the Sample Problem of Paragraph A of Section 3.2.1.1.

Additional Data:

$M = 0.6 \quad \alpha = 8^\circ \quad C_L = 0.185 \quad A_W = 2.91 \quad z = 38.1$ in. $\quad d_w = 25.6$ in.

Compute:

$$\frac{z\, d_w}{144} = \frac{(25.6)(38.1)}{144} = 6.77 \text{ ft}^2$$

$R_i = -0.0025$ (Figure 3.2.2-3)

Solution:

$D_i = 46.875\, C_L\, A_W\, R_i$ (Equation 3.2.2-a)

$= (46.875)(0.185)(2.91)(-0.0025)$

$= -0.063 \text{ ft}^2$

This result is used in the Sample Problem of Paragraph A of Section 3.2.3 as part of the total-drag-increment computation.

B. TRANSONIC

The method presented in Paragraph A of this section is applicable in the transonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is applicable in the supersonic speed range up to a Mach number of 1.6. The user should use caution in extrapolating the method beyond this speed.

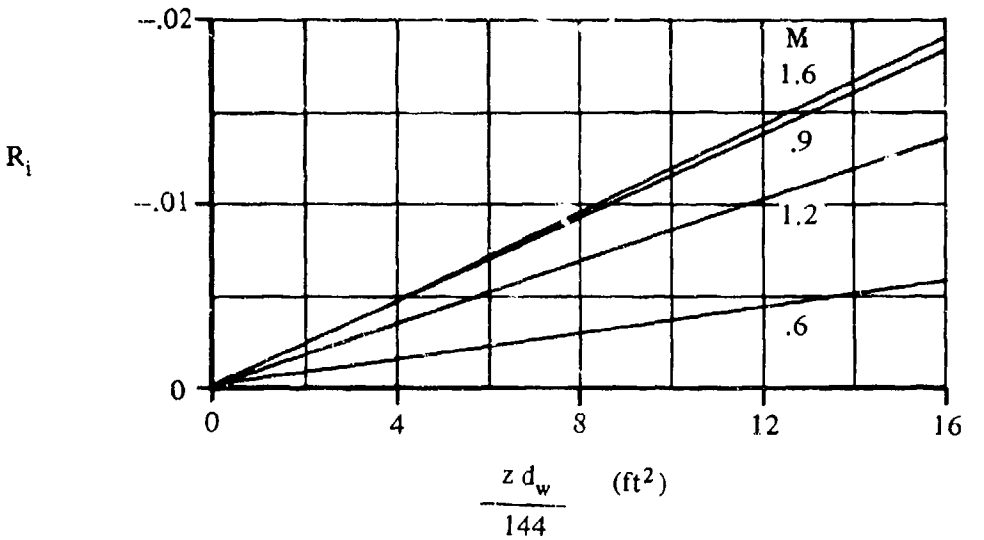

FIGURE 3.2.2-3 NORMALIZED INCREMENTAL DRAG DUE TO LIFT

3.2.3 TOTAL DRAG INCREMENT DUE TO EXTERNAL STORES

A method is presented in this section for estimating the total incremental change in aircraft drag coefficient due to external-store installations. The method predicts the increments for symmetric, asymmetric, and multiple-installation loading configurations. The total drag increment is the sum of the incremental drag at zero lift and the incremental drag due to lift. These components are computed in terms of equivalent-parasite-drag area for each installation by the methods of Sections 3.2.1 and 3.2.2, and combined to obtain the total-drag-coefficient increment by the method of this section.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.2-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The method has been verified for the Mach-number range given in Table 3.2-A. The user should use caution in extrapolating the empirical curves beyond the given Mach-number range.

2. The method is not applicable to wing-tip and wing-tangent-mounted stores.

3. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

4. The angle-of-attack range is from zero to cruise angle of attack.

5. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

6. The method is applicable for sideslip angles less than 4^{o}.

The procedure for computing the total-drag-coefficient increment is a summation process in which equivalent-parasite-drag areas for each store installation (armament station) are added together and divided by the wing reference area. Zero-lift-drag contributions are computed by the methods of Section 3.2.1. These include contributions of the basic installation (computed in Section 3.2.1.1), adjacent-store interference (computed in Section 3.2.1.2), and fuselage interference (computed in Section 3.2.1.3). Drag-due-to-lift contributions are computed in Section 3.2.2.

A. SUBSONIC

DATCOM METHOD

The total-aircraft drag-coefficient increment due to external-store installations and based on wing reference area, S_W, is given by

$$\Delta C_D = \frac{1}{S_W}\left\{\sum_{j=1}^{N_I}(D_B)_j + \sum_{k=0}^{N_P}\left(D_{I_S}\right)_k + \sum_{\ell=0}^{N_F}\left(D_{I_f}\right)_\ell + \sum_{m=1}^{N_I}(D_i)_m\right\} \qquad 3.2.3\text{-a}$$

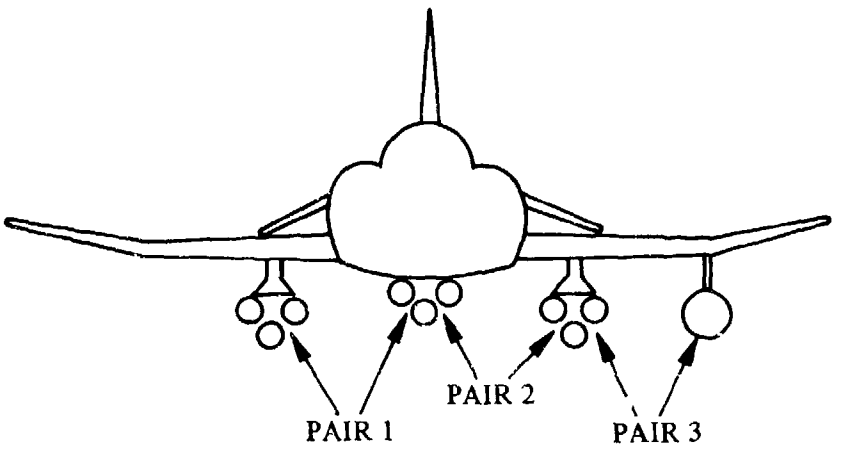
where

S_W is the aircraft wing reference area (ft^2).

N_I is the total number of store installations on the aircraft.

$(D_B)_j$ is the zero-lift equivalent-parasite-drag area (ft^2) at installation j, computed in Section 3.2.1.1.

N_P is the total number of pairs of adjacent-store installations carried. (See Sketch (a).)



SKETCH (a)

$\left(D_{I_S}\right)_k$ is the zero-lift equivalent-parasite-drag area (ft^2) due to the mutual interference of adjacent-store installations for pair k, computed in Section 3.2.1.2.

N_F is the number of store installations adjacent to the fuselage.

$\left(D_{i_f}\right)_\ell$ is the zero-lift equivalent-parasite-drag area (ft^2) due to the mutual interference of store installation ℓ and adjacent fuselage, computed in Section 3.2.1.3.

$(D_i)_m$ is the drag-due-to-lift equivalent-parasite-drag area (ft^2) at installation m, computed in Section 3.2.2.

Reference 1 states that prediction errors for store incremental-drag are nominally 10 to 15 percent, resulting in an overall accuracy within 5 percent of the total-aircraft-drag coefficient. A comparison of test data with results calculated by this method is provided in Table 3.2.3-A. Additional comparisons of test and calculated results are found in Reference 1.

Sample Problem

Given: A swept-wing subsonic fighter aircraft (Reference 2) symmetrically loaded at the inboard-wing stations with pylon-mounted TER's, each containing two 500-lb bombs. This is the same low-wing configuration presented in the Sample Problems of Paragraph A of Section 3.2.1.1 and Paragraph A of Section 3.2.2.

Additional Characteristics:

$M = 0.6$ $\quad S_W = 260\ ft^2$

(Additional geometric data are provided in the Sample Problems of Sections 3.2.1.1 and 3.2.2.)

$D_B = 1.498\ ft^2$ (1 side) (Sample Problem, Paragraph A, Section 3.2.1.1)

$D_i = -0.063\ ft^2$ (1 side) (Sample Problem, Paragraph A, Section 3.2.2)

$D_{I_f} = 0$ (low-wing configuration)

Compute:

$N_I = 2$ (two store installations)

$N_P = 0$ (No pairs of adjacent store installations)

$N_F = 2$

Solution:

$$\Delta C_D = \frac{1}{S_W}\left\{\sum_{j=1}^{N_I}(D_B)_j + \sum_{k=1}^{N_P}\left(D_{I_S}\right)_k + \sum_{\ell=1}^{N_F}\left(D_{I_f}\right)_\ell + \sum_{m=1}^{N_I}(D_i)_m\right\} \quad \text{(Equation 3.2.3-a)}$$

Expanding and noting that $N_P = 0$ and $\left(D_{I_f}\right)_\ell = 0$,

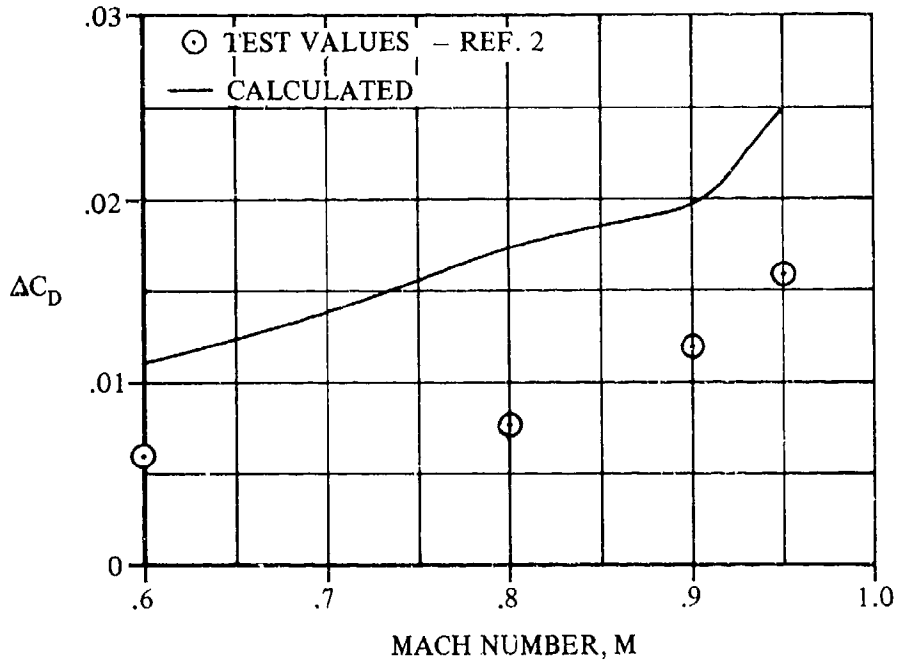
$$\Delta C_D = \frac{1}{S_W}\left[(D_B)_1 + (D_B)_2 + (D_i)_1 + (D_i)_2\right]$$

$$= \frac{1}{S_W}\left[2D_B + 2D_i\right] \quad \text{(symmetrical installations)}$$

$$= \frac{1}{260}\left[(2)(1.498) + (2)(-0.063)\right]$$

$$= 0.0110$$

Values of ΔC_D at other Mach numbers are shown in comparison to test data from Reference 2 in Sketch (b).



SKETCH (b)

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The user is cautioned that due to the difficulties of predicting drag in the transonic region (especially interference effects), the method is generally less accurate than in the subsonic and supersonic speed ranges.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range up to the Mach-number limits indicated in Table 3.2-A. Caution should be used when extrapolating data from the figures beyond the given Mach-number range since the method has not been substantiated beyond these limits.

3.3 EFFECT OF EXTERNAL STORES ON AIRCRAFT NEUTRAL POINT

Methods are presented in this section for estimating the incremental shift in aircraft neutral point due to external-store installations. By computing a neutral-point shift due to external stores, the methods are actually indicating a stability change in terms of a change in slope of the $C_M - C_L$ curve. For most configurations the effect of store loadings is to destabilize the basic aircraft, although some loadings can result in a stabilizing tendency. The methods are taken from Reference 1 and are empirical in nature.

Section 3.3 is subdivided as follows:

Section 3.3.1 Neutral-Point Shift Due to Lift Transfer from Clean Aircraft.
Section 3.3.2 Neutral-Point Shift Due to Interference Effects on Wing Flow Field.
Section 3.3.3 Neutral-Point Shift Due to Change in Tail Effectiveness.
Section 3.3.4 Total Neutral-Point Shift Due to External Stores.

The total neutral-point shift is the sum of the shifts computed by the methods of Sections 3.3.1, 3.3.2, and 3.3.3.

The Datcom Methods are applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The methods are limited to the store-loading configurations and Mach-number range presented in Table 3.3-A. The methods are applicable to mixed loading configurations obtained by combining two or more loadings specified in Table 3.3-A. The methods are subject to additional limitations specifically noted in each of the sections that follow.

REFERENCE

1. Gallagher, R. D., Jimenez, G., Light, L. E., and Thames, F. C.: Technique for Predicting Aircraft Aerodynamic Effects Due to External Stores Carriage, AFFDL-TR-75-95, Volumes I and II, 1975. (U)

3.3.1 NEUTRAL-POINT SHIFT DUE TO LIFT TRANSFER FROM STORE INSTALLATION TO CLEAN AIRCRAFT

A method is presented in this section for estimating the neutral-point shift due to the transfer of the lifting characteristics from the external-store installations to the clean aircraft. The method predicts a neutral-point shift due to all installations (armament stations) on the aircraft. Wing-flow-field interference and horizontal-tail effects are not included in this section (see Sections 3.3.2 and 3.3.3).

The Datcom Method is taken from Reference 1 and is basically theoretical in concept with empirically-determined factors and coefficients. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.3-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The method is not applicable to wing-tip or wing-tangent-mounted stores.

2. The method has been verified for the Mach-number range given in Table 3.3-A. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.

3. The method has not been verified for configurations in which flaps, slats or other flow-disrupting devices are deployed.

4. The method gives the best results for an angle-of-attack range from 0 to 8^{o}, although the method can be used for higher angles of attack.

5. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

6. The method is applicable for sideslip angles less than 4^{o}.

7. Fuselage-mounted installations must be located on the fuselage centerline.

8. The method is not applicable to empty multiple racks.

9. The effect of empty pylons on neutral point is considered to be negligible.

The effect due to a pair of symmetrical installations can be computed by doubling the effect of one side.

A. SUBSONIC

DATCOM METHOD

The neutral-point shift in inches, positive for aft shift, due to the transfer of lift from the store installations to the clean aircraft is given by

$$\Delta x_{n.p._1} = \frac{\sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} K_{S_{ij}} C_{L_{\alpha_{S_{ij}}}} \left(x_{S_{ij}} - x_{a.c.}\right)}{C_{L_{\alpha_{WB}}} + \sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} K_{S_{ij}} C_{L_{\alpha_{S_{ij}}}}} \qquad 3.3.1\text{-a}$$

where

N_I is the total number of store installations.

i is the store-installation number.

n_{s_i} is the number of store stations on installation i (including empty stations).

j is the store number on installation i.

$C_{L_{\alpha_{S_{ij}}}}$ is the free-stream lift-curve slope of store j on installation i given by

$$C_{L_{\alpha_{S_{ij}}}} = \frac{375}{S_W}\left[\left(C_{L_\alpha}\right)_{SB}\left(K_{NB}\right) + \left(C_{L_\alpha}\right)_{SF}\right] \text{ (per deg)} \qquad 3.3.1\text{-b}$$

where

S_W is the aircraft wing reference area (ft^2).

$\left(C_{L_\alpha}\right)_{SB}$ is the store-body lift-curve slope (per deg) obtained from Figure 3.3.1-16 as a function of store-body planform area, S_p ($in.^2$).

K_{NB} is a nose-shape parameter given by

$$K_{NB} = 1.0 \text{ for } \theta_n \leqslant 22^o \qquad 3.3.1\text{-c}$$

$$K_{NB} = 1.0 + 0.65\,\frac{(\theta_n - 22)}{68} \text{ for } 22^o < \theta_n \leqslant 90^o \qquad 3.3.1\text{-d}$$

where

θ_n is the store-nose half-cone angle (deg).

$\left(C_{L_\alpha}\right)_{SF}$ is the store-fin lift-curve slope (per deg) given by

$$\left(C_{L_\alpha}\right)_{SF} = (0.191)(10^{-6})(B_e)^2 \qquad 3.3.1\text{-e}$$

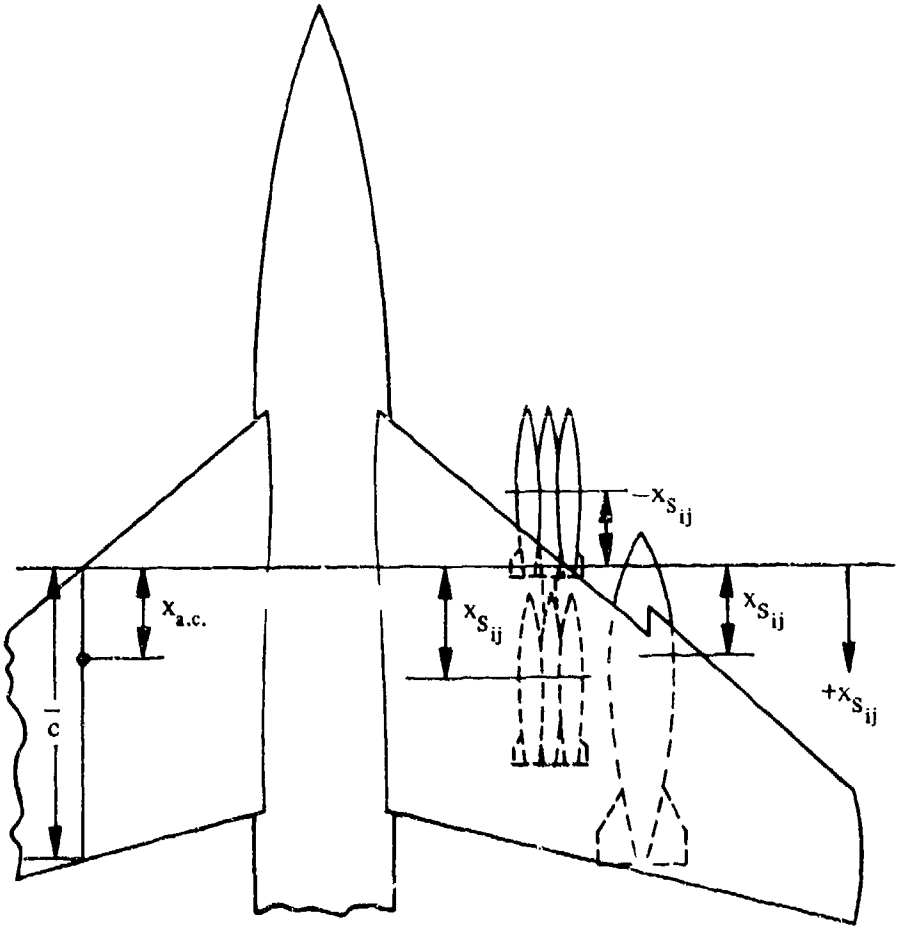
where

$$B_e = 0 \text{ for } b_F \leqslant d_S \qquad 3.3.1\text{-f}$$

$$B_e = b_F - d_S \text{ for } b_F > d_S \qquad 3.3.1\text{-g}$$

where b_F and d_S are the store-fin span and maximum store diameter (in.), respectively.

$x_{S_{ij}}$ is the distance (in.) from the leading edge of the mean aerodynamic chord $\bar{c}$, to the point midway between the mounting lugs of the installed store for store j on installation i, positive in the aft direction. (See Sketch (a).)



SKETCH (a)

$x_{a.c.}$ is the wing-body aerodynamic-center location of the clean aircraft measured from the leading edge of the wing mean aerodynamic chord (in.). (See Sketch (a).) This value should be obtained from test data or estimated by using Section 4.3.2.2.

$C_{L_{\alpha_{WB}}}$ is the wing-body clean-aircraft lift-curve slope (per deg) obtained from test data or estimated by using Section 4.3.1.2.

$K_{S_{ij}}$ is an empirical factor related to installation type, mounting position, and Mach number and is specified as follows:

1. Wing-Pylon-Mounted Single Store:

In this case $n_{s_i} = 1$ and hence j = 1.

$$K_{S_{ij}} = F_1\left(\bar{x}_{SN_{ij}}, F_R\right) + F_2\left(\bar{x}_{SN_{ij}}, z_{ij}, F_R\right) \quad i = 1, \ldots N_I \qquad 3.3.1\text{-h}$$

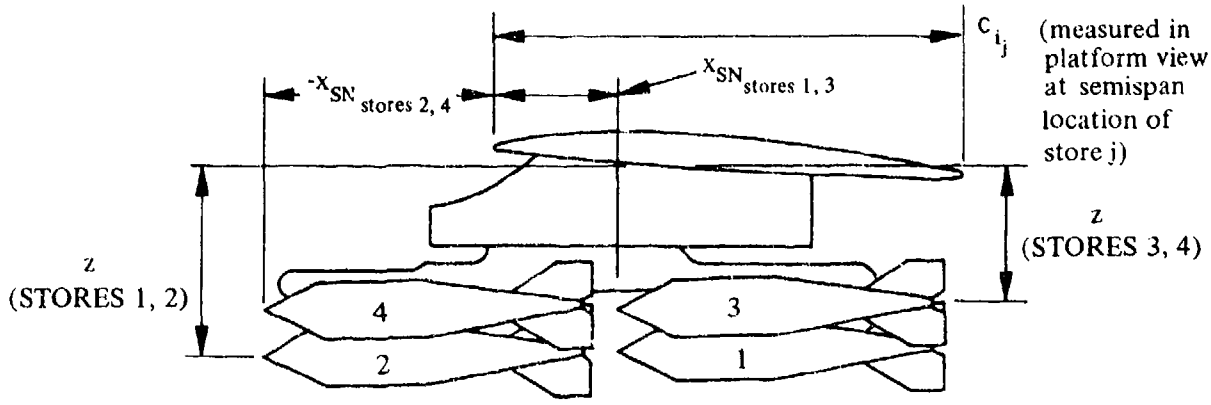
where $F_1\left(\bar{x}_{SN_{ij}} F_R\right)$ is a parameter based on store longitudinal placement and fin-area ratio obtained from Figure 3.3.1-17.

where

$$\bar{x}_{SN_{ij}} = \frac{x_{SN_{ij}}}{c_{ij}} \text{ for } j = 1 \qquad 3.3.1\text{-i}$$

where

$x_{SN_{ij}}$ is the distance from the local wing leading edge to nose of store j on installation i, positive in the aft direction (in.). (See Sketch (b).)



SKETCH (b)

c_{ij} is the local wing chord at the semispan location of store j on store installation i, (in.). (See Sketch (b).)

F_R is given by

$$F_R = \frac{S_F}{S_p} \qquad 3.3.1\text{-j}$$

where

S_F is the store-fin area projected onto a horizontal plane ($in.^2$).

S_p is the store-body planform area ($in.^2$).

$F_2\left(\bar{x}_{SN_{ij}}, \bar{z}_{ij}, F_R\right)$ is given by

$$F_2\left(\bar{x}_{SN_{ij}}, \bar{z}_{ij}, F_R\right) = F_{21}\left(\bar{x}_{SN_{ij}}\right) F_{22}(\bar{z}_{ij})\, F_{23}(F_R) \qquad 3.3.1\text{-k}$$

where

$F_{21}\left(\bar{x}_{SN_{ij}}\right)$ is a store longitudinal-placement factor obtained from Figure 3.3.1-18a where $\bar{x}_{SN_{ij}}$ is given by Equation 3.3.1-i.

$F_{22}(\bar{z}_{ij})$ is a store vertical-placement factor obtained from Figure 3.3.1-18b where $\bar{z}_{ij}$ is obtained from

$$\bar{z}_{ij} = \frac{z_{ij}}{c_{ij}} \text{ for } j = 1 \qquad 3.3.1\text{-}\ell$$

where

z_{ij} is the vertical distance from the average wing lower surface location to the centerline of store j on installation i, positive in downward direction (in.). (See Sketch (b).)

c_{ij} is the local wing chord at the semispan location of store j on store installation i (in.). (See Sketch (b).)

$F_{23}(F_R)$ is a store-fin area-ratio factor obtained from Figure 3.3.1-19a where F_R is given by Equation 3.3.1-j.

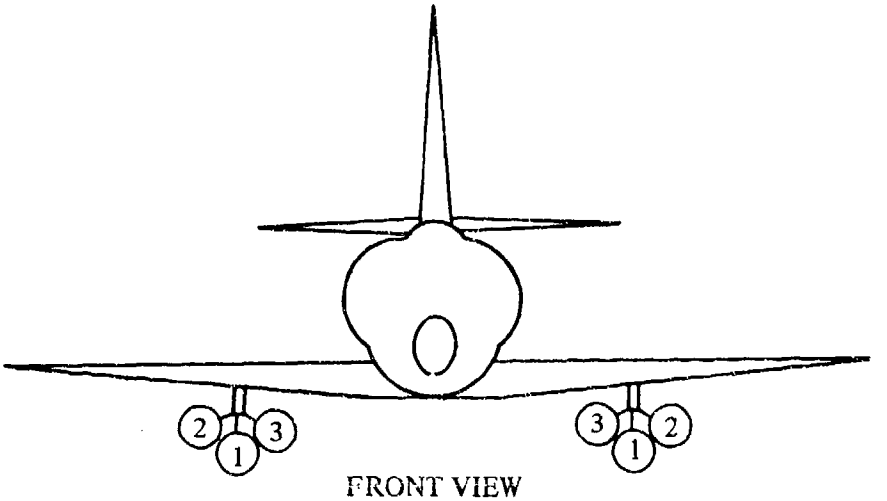
2. Wing-Pylon-Mounted TER (For TER installations it is essential that the store stations be identified in the same manner as indicated in Sketch (c).)

$$K_{S_{ij}} = F_1\left(\bar{x}_{SN_{ij}}\right) + F_2(M, j) \quad j = 1, 2, 3 \qquad 3.3.1\text{-m}$$

where

$F_1\left(\bar{x}_{SN_{ij}}\right)$ is a store longitudinal-placement parameter for TER carriage obtained from Figure 3.3.1-19b where $\bar{x}_{SN_{ij}}$ is given by Equation 3.3.1-i.

$F_2(M, j)$ is the TER Mach and store-station effect parameter obtained from Figures 3.3.1-20a through -20c as a function of Mach number and TER store-station number, j, where j refers to the TER station number defined in Sketch (c).



FRONT VIEW

SKETCH (c)

3. Wing-Pylon-Mounted MER (For MER installations it is essential that the store stations be identified in the same manner as indicated in Sketch (d).)

$$K_{S_{ij}} = F_1\left(\bar{x}_{SN_{ij}}\right) + F_2\left(\bar{x}_{SN_{ij}}, \bar{z}_{ij}, M\right) + F_3(M, j) \qquad 3.3.1\text{-n}$$

where

$F_1\left(\bar{x}_{SN_{ij}}\right)$ is a store longitudinal-placement parameter for MER carriage obtained from Figure 3.3.1-21 where $\bar{x}_{SN_{ij}}$ is given by Equation 3.3.1-i.

$F_2\left(\bar{x}_{SN_{ij}}, \bar{z}_{ij}, M\right)$ is given by

$$F_2\left(\bar{x}_{SN_{ij}}, \bar{z}_{ij}, M\right) = F_{21}\left(\bar{x}_{SN_{ij}}\right) F_{22}(\bar{z}_{ij})\, F_{23}(M) \qquad 3.3.1\text{-o}$$

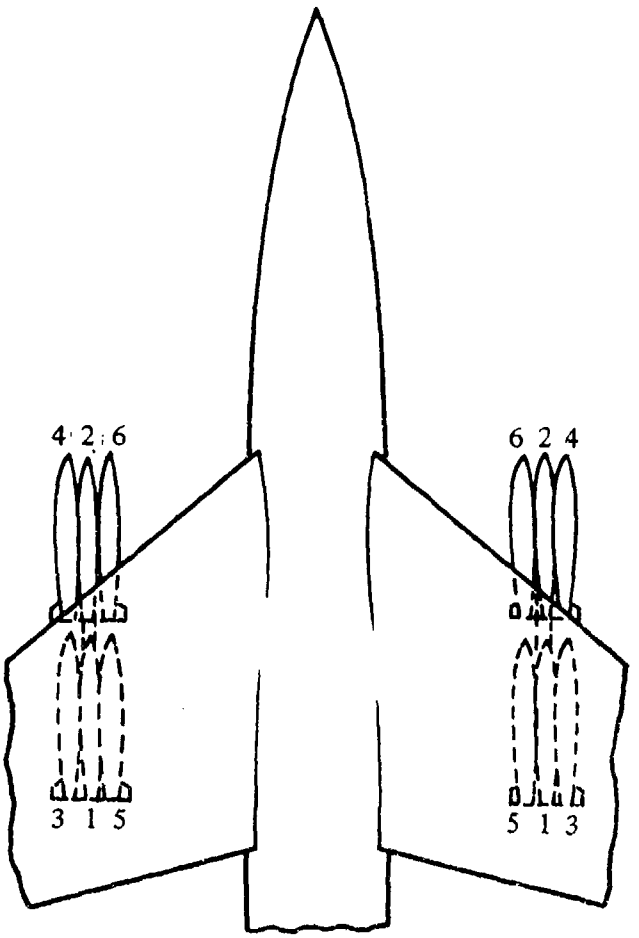
where $\bar{z}_{ij}$ is defined by Equation 3.3.1-ℓ, and

$F_{21}\left(\bar{x}_{SN_{ij}}\right)$ is a MER store longitudinal-placement factor obtained from Figures 3.3.1-22a and -22b.

$F_{22}(\bar{z}_{ij})$ is a MER store vertical-placement factor obtained from Figures 3.3.1-23a and -23b.

$F_{23}(M)$ is a MER Mach-effect factor obtained from Figures 3.3.1-24a and -24b.

$F_3(M, j)$ is the MER Mach and store-station effect parameter obtained from Figures 3.3.1-25a through -25f as a function of Mach number and MER store-station number, j, where j refers to the MER store-station number defined in Sketch (d).



TOP VIEW

SKETCH (d)

4. Fuselage-Centerline-Mounted Single Carriage

In this case $n_{s_j} = 1$ and hence j = 1

$$K_{S_{ij}} = 0.10 \qquad 3.3.1\text{-p}$$

5. Fuselage-Centerline-Tangent-Mounted MER (For fuselage MER installations, use the right wing numbering scheme of Sketch (d) for numbering the store station locations.)

$$K_{S_{ij}} = I_{S_j} [F_1(M) + F_2(M, j)] \quad (j = 1, 2, 3, 4, 5, 6) \qquad 3.3.1\text{-q}$$

where j coincides with the MER station number defined by Sketch (d).

For j = 1, 2

$$I_{S_j} = 1.0 \qquad 3.3.1\text{-r}$$

For j = 3, 4, 5, 6

I_{S_j} is a neutral-point correlation factor for stores on a MER installation obtained from Figure 3.3.1-27a as a function of d_{wing}/c_r where d_{wing} is the distance (in.) from the fuselage lower surface at the store midpoint to the average wing lower surface at the wing root and c_r is the wing root chord (in.).

$F_1(M)$ is a MER Mach-effect factor for fuselage-tangent-mounted installations obtained from Figure 3.3.1-27b as a function of Mach number.

$F_2(M, j)$ is a MER Mach and store-station effect parameter for fuselage-tangent-mounted installations obtained from Figures 3.3.1-28a through -28d as a function of Mach number and MER station, j.

6. Fuselage-Centerline-Pylon-Mounted MER (For fuselage MER installations, use the right wing numbering scheme of Sketch (d) for numbering the store station locations.)

For j = 1, 3, 5 where j are the MER stations defined in Sketch (d),

$$K_{S_{ij}} = I_{S_j} F_1(M) \qquad 3.3.1\text{-s}$$

where

I_{S_j} is defined for Configuration 5.

$F_1(M)$ is a MER Mach-effect factor for fuselage-pylon-mounted installations obtained from Figure 3.3.1-30a as a function of Mach number and MER station, j.

For j = 2,

$$K_{S_{ij}} = F_1(M) \qquad 3.3.1\text{-t}$$

where

$F_1(M)$ is obtained from Figure 3.3.1-45b

For j = 4, 6

$$K_{S_{ij}} = I_{S_j} [F_1(M) + F_2(M, j)] \qquad 3.3.1\text{-u}$$

where

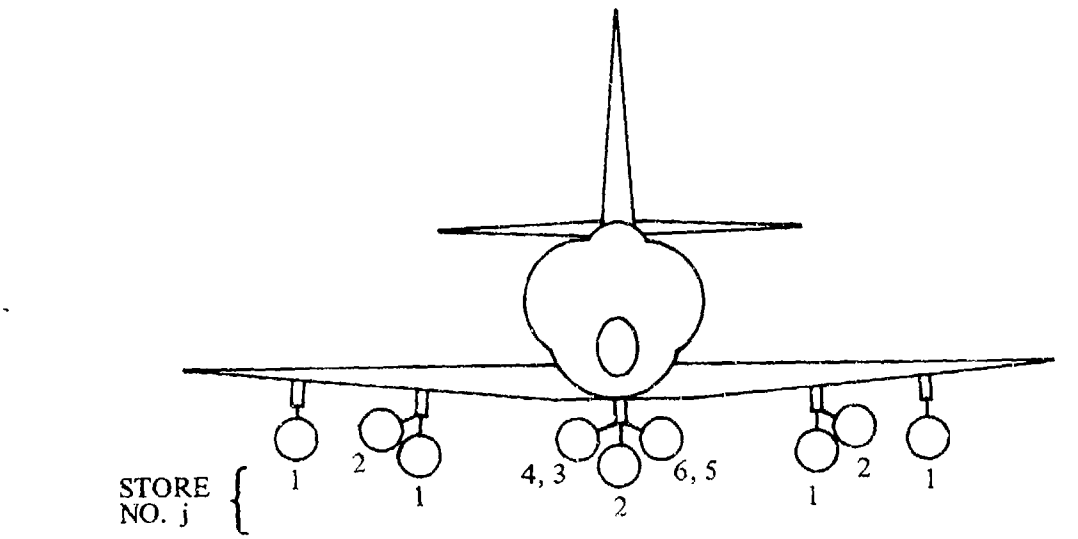
I_{S_j} is defined for Configuration 5.

$F_1(M)$ is a MER Mach-effect factor for fuselage-pylon-mounted installations obtained from Figure 3.3.1-30b as a function of Mach number and MER station, j.

$F_2(M, j)$ is a MER Mach and store-station effect parameter for fuselage-pylon-mounted installations obtained from Figure 3.3.1-31 as a function of configuration and Mach number.

Sample Problem

Given: A swept-wing subsonic fighter aircraft from Reference 2, symmetrically loaded as follows:



FRONT VIEW

i	j	Wing Semispan Station, y_{ij} (in.)	c_{ij} (in.)
1,5	1	113.75	87.8
2,4	2	87.00	111.0
2,4	1	78.80	119.0

Isolated-Store Data:

$d_S = 12.0$ in. $\quad S_P = 700\ in.^2$ $\quad S_F = 94\ in.^2$

$b_F = 14.7$ in. $\quad \dot{\theta}_n = 17^o$

Store Installation Data:

Installation Number, i	Store No., j	$x_{SN_{ij}}$ (in.)	$x_{S_{ij}}$ (in.)	z_{ij} (in.)	y_{ij} (in.)
2,4	1	−21.7	31.7	–	78.8.
2,4	2	−30.0	31.7	–	87.0
1,5	1	−23.2	61.2	17.6	113.75
3	3,5	–	71.7	–	0
3	2,4,6	–	−22.4	–	0

Additional Data:

$M = 0.6$ $\quad \alpha = 8^o$

Compute:

To identify the terms that need to be computed, expand Equation 3.3.1-a for the N_I store installations and n_{s_i} stores on each installation. Since the aircraft is symmetrically loaded with respect to the fuselage centerline, installations 1 and 5 are identical, as are 2 and 4. Therefore, it is only necessary to compute the terms (in Equation 3.3.1-a) for installations 1 and 2, and then double their values. The results are then added to the terms for installation 3. The indices for the summation process are summarized in the table below:

i	n_{s_i}	Actual Store Stations Loaded on Installation i
1	1	j = 1
2	3	j = 1, 2
3	6	j = 2, 3, 4, 5, 6

Note that for i = 2, station 3 is not loaded and for i = 3, station 1 is not loaded. Therefore, terms for these locations are set equal to zero.

$\Delta x_{n.p._1}$ numerator (from Equation 3.3.1-a):

$$\sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} K_{S_{ij}} C_{L_{\alpha_{ij}}} \left(x_{S_{ij}} - x_{a.c.}\right) =$$

$$2\left[K_{S_{11}} C_{L_{\alpha_{S_{11}}}} \left(x_{S_{11}} - x_{a.c.}\right) + K_{S_{21}} C_{L_{\alpha_{S_{21}}}} \left(x_{S_{21}} - x_{a.c.}\right)\right.$$

$$\left. + K_{S_{22}} C_{L_{\alpha_{S_{22}}}} \left(x_{S_{22}} - x_{a.c.}\right)\right] + K_{S_{32}} C_{L_{\alpha_{S_{32}}}} \left(x_{S_{32}} - x_{a.c.}\right)$$

$$+ K_{S_{33}} C_{L_{\alpha_{S_{33}}}} \left(x_{S_{33}} - x_{a.c.}\right) + K_{S_{34}} C_{L_{\alpha_{S_{34}}}} \left(x_{S_{34}} - x_{a.c.}\right)$$

$$+ K_{S_{35}} C_{L_{\alpha_{S_{35}}}} \left(x_{S_{35}} - x_{a.c.}\right) + K_{S_{36}} C_{L_{\alpha_{S_{36}}}} \left(x_{S_{36}} - x_{a.c.}\right)$$

$\Delta x_{n.p._1}$ denominator (from Equation 3.3.1-a):

$$C_{L_{\alpha_{WB}}} + \sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} K_{S_{ij}} C_{L_{\alpha_{S_{ij}}}} =$$

$$C_{L_{\alpha_{WB}}} + 2\left[K_{S_{11}} C_{L_{\alpha_{S_{11}}}} + K_{S_{21}} C_{L_{\alpha_{S_{21}}}} + K_{S_{22}} C_{L_{\alpha_{S_{22}}}}\right] + K_{S_{32}} C_{L_{\alpha_{S_{32}}}} + K_{S_{33}} C_{L_{\alpha_{S_{33}}}}$$

$$+ K_{S_{34}} C_{L_{\alpha_{S_{34}}}} + K_{S_{35}} C_{L_{\alpha_{S_{35}}}} + K_{S_{36}} C_{L_{\alpha_{S_{36}}}}$$

For Installation 1 (Wing-Pylon-Mounted Single Store)

$$\bar{x}_{SN_{11}} = \frac{x_{SN_{11}}}{c_{11}} = \frac{-23.2}{87.8} = -0.264 \qquad \text{(Equation 3.3.1-i)}$$

$$F_R = \frac{S_F}{S_P} = \frac{94}{700} = 0.134 \qquad \text{(Equation 3.3.1-j)}$$

$$\bar{z}_{11} = \frac{z_{11}}{c_{11}} = \frac{17.6}{87.8} = 0.200 \qquad \text{(Equation 3.3.1-ℓ)}$$

$$F_1\left(\bar{x}_{SN_{11}}, F_R\right) = -0.035 \qquad \text{(Figure 3.3.1-17)}$$

$$F_{21}\left(\bar{x}_{SN_{11}}\right) = 1.70 \qquad \text{(Figure 3.3.1-18a)}$$

$$F_{22}(\bar{z}_{11}) = 0 \qquad \text{(Figure 3.3.1-18b)}$$

$$F_{23}(F_R) = -0.53 \qquad \text{(Figure 3.3.1-19a)}$$

$$F_2\left(\bar{x}_{SN_{11}}, \bar{z}_{11}, F_R\right) = F_{21}\left(\bar{x}_{SN_{11}}\right) F_{22}(\bar{z}_{11}) F_{23}(F_R) \qquad \text{(Equation 3.3.1-k)}$$

$$= (1.70)(0)(-0.53) = 0$$

$$K_{S_{11}} = F_1\left(\bar{x}_{SN_{11}}, F_R\right) + F_2\left(\bar{x}_{SN_{11}}, \bar{z}_{11}, F_R\right) \qquad \text{(Equation 3.3.1-h)}$$

$$= -0.035 + 0 = -0.035$$

$$\left(C_{L_\alpha}\right)_{SB} = 0.161 \times 10^{-3} \text{ per deg} \qquad \text{(Figure 3.3.1-16)}$$

$$K_{NB} = 1.0 \qquad \text{(Equation 3.3.1-c, } \theta_n < 22^o\text{)}$$

$$B_e = b_F - d_S = 2.70 \qquad \text{(Equation 3.3.1-g, } b_F > d_S\text{)}$$

$$\left(C_{L_\alpha}\right)_{SF} = (0.191)(10^{-6})(B_e^2) \qquad \text{(Equation 3.3.1-e)}$$

$$= (0.191 \times 10^{-6})(2.7)^2$$

$$= 1.392 \times 10^{-6} \text{ per deg}$$

$$C_{L_{\alpha_{S_{11}}}} = \frac{375}{S_W}\left[\left(C_{l_\alpha}\right)_{SB} K_{NB} + \left(C_{L_\alpha}\right)_{SF}\right] \qquad \text{(Equation 3.3.1-b)}$$

$$= \frac{375}{260}\left[(0.161 \times 10^{-3})(1) + 1.392 \times 10^{-6}\right]$$

$$= 0.000233 \text{ per deg}$$

Noting that all stores are identical in this problem,

$C_{L_{\alpha_{S_{ij}}}} = 0.000233$ per deg for all i, j.

For Installation 2 (Wing-Pylon-Mounted TER)

$$\bar{x}_{SN_{21}} = \frac{x_{SN_{21}}}{c_{21}} = \frac{-21.7}{119.0} = -0.182 \qquad \text{(Equation 3.3.1-i)}$$

$$\bar{x}_{SN_{22}} = \frac{x_{SN_{22}}}{c_{22}} = \frac{-30.0}{111.0} = -0.270$$

$$\left.\begin{aligned} F_1\left(\bar{x}_{SN_{21}}\right) &= 0.280 \text{ (centerline sta., j = 1)} \\ F_1\left(\bar{x}_{SN_{22}}\right) &= 0.710 \text{ (shoulder sta., j = 2)} \end{aligned}\right\} \qquad \text{(Figure 3.3.1-19b)}$$

$F_2(M, j) = 0$ for $j = 1$ (Figure 3.3.1-20a)

$F_2(M, j) = 0$ for $j = 2$ (Figure 3.3.1-20b)

$$K_{S_{ij}} = F_1\left(\bar{x}_{SN_{ij}}\right) + F_2(M, j) \qquad \text{(Equation 3.3.1-m)}$$

$$K_{S_{21}} = 0.280 + 0 = 0.280$$

$$K_{S_{22}} = 0.710 + 0 = 0.710$$

For Installation 3 (Fuselage-Centerline-Pylon-Mounted MER)

There are five stores on this installation, therefore determine $K_{S_{ij}} = K_{S_{3j}}$ where $j = 2, 3, 4, 5, 6$

For $j = 2$

$F_1(M) = 0.45$ (Figure 3.3.1-30b)

$K_{S_{ij}} = F_1(M)$ (Equation 3.3.1-t)

$K_{S_{32}} = 0.45$

For $j = 3, 5$

$\frac{d_{wing}}{c_r} = \frac{0}{186} = 0$

$I_{S_j} = 0$ for $j = 3, 5$ (Figure 3.3.1-27a)

$F_1(M) = 0.042$ (Figure 3.3.1-30a)

$K_{S_{ij}} = I_{S_j} F_1(M)$ (Equation 3.3.1-s)

$K_{S_{33}} = K_{S_{35}} = (0)(0.042) = 0$

For $j = 4, 6$

$I_{S_j} = 0$ for $j = 4, 6$ (Figure 3.3.1-27a)

$F_1(M) = 0.45$ for $j = 4, 6$ (Figure 3.3.1-30b)

$F_2(M, j) = 0$ for $j = 4, 6$ (Figure 3.3.1-31)

$K_{S_{ij}} = I_{S_j} [F_1(M) + F_2(M, j)]$ (Equation 3.3.1-u)

$K_{S_{34}} = K_{S_{36}} = (0)[0.45 + 0] = 0$

Substituting into the $\Delta x_{n.p._1}$ numerator:

$$\sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} K_{S_{ij}} C_{L_{\alpha_{S_{ij}}}} \left(x_{S_{ij}} - x_{a.c.}\right) = 2\Big[(-0.035)(0.000233)(61.2 - 33.05) + (0.280)(0.000233)(31.7 - 33.05) + (0.710)(0.000233)(31.7 - 33.05)\Big]$$

$$+ (0.45)(0.000233)(-22.4 - 33.05)$$

$$= -0.006896$$

Substituting into the $\Delta x_{n.p._1}$ denominator:

$$C_{L_{\alpha_{WB}}} + \sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} K_{S_{ij}} C_{L_{\alpha_{S_{ij}}}} = 0.060 + 2\,[(-0.035)(0.000233) + (0.28)(0.000233) + (0.710)(0.000233)] + (0.45)(0.000233)$$

$$= 0.06055$$

Solution:

$$\Delta x_{n.p._1} = \frac{\text{Numerator}}{\text{Denominator}} = \frac{-0.006896}{0.06055} = -0.114 \text{ in.}$$

The calculated values of $\Delta x_{n.p._1}$ are summed with $\Delta x_{n.p._2}$ and $\Delta x_{n.p._3}$ (computed in Sections 3.3.2 and 3.3.3, respectively) in the Sample Problem of Section 3.3.4 to obtain the total shift in neutral point.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The expected accuracy of the method is less than that in the subsonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range up to a Mach number of 1.6 to 2.0 as indicated in Table 3.3-A. The maximum Mach number provided in the figures should indicate the level to which the method is substantiated. Caution should be used when extrapolating the data beyond the Mach range provided in the figures.

3.3.2 NEUTRAL-POINT SHIFT DUE TO INTERFERENCE EFFECTS ON WING FLOW FIELD

A method is presented in this section for estimating the neutral-point shift due to interference effects on the wing flow field from external-store installations. The method predicts a neutral-point shift due to all installations (armament stations) on the aircraft.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.3-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The method is not applicable to wing-tip or wing-tangent-mounted stores.
2. The method has been verified for the Mach-number range given in Table 3.3-A. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.
3. The method has not been verified for configurations in which flaps, slats or other flow-disrupting devices are deployed.
4. The method gives the best results for angle-of-attack range from 0 to 8°, although the method can be used for higher angles of attack.
5. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.
6. The method is applicable for sideslip angles less than 4°.
7. Fuselage-mounted installations must be located on the fuselage centerline.
8. The method is not applicable to empty multiple racks.
9. The effect of empty pylons on neutral point is considered to be negligible.

The effect due to a pair of symmetrical installations can be computed by doubling the effect of one side.

A. SUBSONIC

DATCOM METHOD

The neutral-point shift in inches, positive for aft shift, due to wing flow-field interference effects is given by

$$\Delta x_{n.p._2} = \left(\frac{S_W}{N_I}\right)\left(\sum_{i=1}^{N_I}\sum_{j=1}^{n_{s_i}} C_{L_{\alpha_{S_{ij}}}}\right)\left[\sum_{i=1}^{N_I} \delta S_i \left(\Delta x'_{n.p._2} + K_1 K_2 K_3\right)_i\right] \qquad 3.3.2\text{-a}$$

where

S_W is tl. .. ng reference area (ft^2).

N_I is the total number of store installations on the aircraft.

n_{s_i} is the number of store stations on installation i (including empty stations).

$C_{L_{\alpha_{S_{ij}}}}$ is the free-stream lift-curve slope of store j on installation i (per deg) given by Equation 3.3.1-b.

δ_{S_i} is a parameter related to configuration:

1. For Wing-Pylon Single Carriage:

$$\delta_{S_i} = 20 \qquad \text{3.3.2-b}$$

2. For Wing-Pylon M .R and TER Carriage, and Centerline Single Carriage:

$$\delta_{S_i} = 10 \qquad \text{3.3.2-c}$$

3. For Fuselage-Centerline MER Carriage:

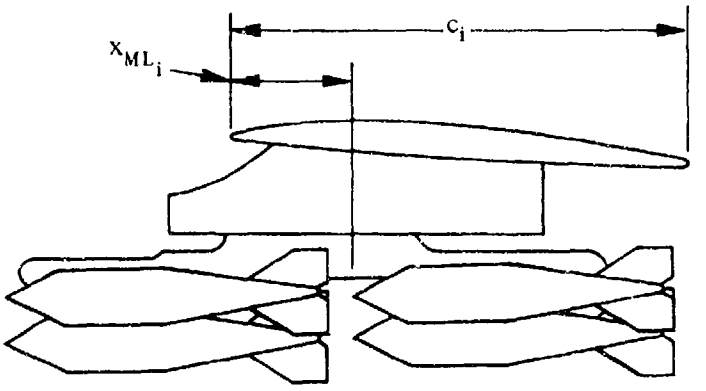
$$\delta_{S_i} = 17.4 \qquad \text{3.3.2-d}$$

$\Delta x'_{n.p._2}$ is a neutral-point basic-interference-effect term obtained from Figures 3.3.2-6a through -6d as a function of configuration and Mach number.

K_1 is a span-location-correction factor obtained from Figures 3.3.2- 8a through - 8c as a function of configuration and $\frac{y_i}{b_W/2}$, where y_i is the wing semispan location of installation i and b_W is the wing span.

Note: For fuselage-mounted installations, $K_1 = 1$.

K_2 is a longitudinal-correction factor obtained from Figure 3.3.2-9a through -9d as a function of x_{ML_i}/c_i, where x_{ML_i} is the distance (in.) from the local wing leading edge to the point midway between the pylon mounting lugs on installation i (positive for the pylon mid-lug point aft of the local wing leading edge), and c_i is the local wing chord (in.) at the semispan location of store installation i. (See Sketch (a).)



SKETCH (a)

K_3 is a Mach-number-correction factor obtained from Figures 3.3.2-11a through -11d as a function of configuration and Mach number.

Sample Problem

Given: A swept-wing subsonic-fighter aircraft from Reference 2 described in the Sample Problem of Paragraph A of Section 3.3.1.

Additional Data:

$C_{L_{\alpha_{S_{ij}}}}$ = 0.000233 per deg (Sample Problem, Paragraph A, Section 3.3.1)

$M = 0.6$

$b_W/2 = 165$ in.

Installation No., i	1,5	2,4	3
x_{ML_i}/c_i	0.204	0.180	0.445
y_i	113.75	78.8	0

Compute:

$$\frac{S_W}{N_I} = \frac{260}{5} = 52.0 \qquad \text{(first term of Equation 3.3.2-a)}$$

Since all stores are identical and there are a total of 11 stores,

$$\sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} C_{L_{\alpha_{S_{ij}}}} = 11\, C_{L_{\alpha_{S_{ij}}}} \qquad \text{(second term of Equation 3.3.2-a)}$$

$$= (11)(0.000233)$$

$$= 0.00256 \text{ per deg}$$

Since the wing installations 1 and 2 are symmetrical, only one side is calculated and the result multiplied by 2.

δ_{S_1} = 20 (Equation 3.3.2-b)

δ_{S_1} = 10 (Equation 3.3.2-c)

δ_{S_3} = 17.4 (Equation 3.3.2-d)

For Installation 1 (Wing-Pylon-Mounted Single Store)

$\Delta x'_{n.p._2}$ = −0.03 (Figure 3.3.2-6a)

$y_i/(b_W/2)$ = 0.689

K_1 = 0 (Figure 3.3.2-8a)

K_2 = 0 (Figure 3.3.2-9a)

K_3 = −0.39 (Figure 3.3.2-11a)

For Installation 2 (Wing-Pylon-Mounted TER)

$\Delta x'_{n.p._2}$ = −0.02 (Figure 3.3.2-6b)

$y_i/(b_W/2)$ = 0.478

K_1 = 0 (Figure 3.3.2-8b)

K_2 = 0.37 (Figure 3.3.2-9b)

K_3 = −0.25 (Figure 3.3.2-11b)

For Installation 3 (Fuselage-Centerline-Pylon-Mounted MER)

$\Delta x'_{n.p._2}$ = 0.125 (Figure 3.3.2-6d)

K_1 = 1.0 (Fuselage-mounted installation)

K_2 = 1.0 (Figure 3.3.2-9d)

K_3 = 0 (Figure 3.3.2-11d)

$$\sum_{i=1}^{N_I} \delta_{S_i} \left(\Delta x'_{n.p._2} + K_1 K_2 K_3\right)_i = {}_2\delta_{S_1} \left(\Delta x'_{n.p._2} + K_1 K_2 K_3\right)_{i=1} \quad \text{(third term of Equation 3.3.2-a)}$$

$$+ {}_2\delta_{S_2} \left(\Delta x'_{n.p._2} + K_1 K_2 K_3\right)_{i=2}$$

$$+ \delta_{S_3} \left(\Delta x'_{n.p._3} + K_1 K_2 K_3\right)_{i=3}$$

$$= (2)(20)\,[-0.03 + (0)(0)(-0.39)]$$

$$+ (2)(10)[-0.02 + (0)(0.37)(-0.25)]$$

$$+ (17.4)[0.125 + (1.0)(1.0)(0)]$$

$$= 0.575$$

Solution:

$$\Delta x_{n.p._2} = \left(\frac{S_W}{N_I}\right)\left(\sum_{i=1}^{N_I} \sum_{j=1}^{n_{s_i}} C_{L_{\alpha_{S_{ij}}}}\right) \left[\sum_{i=1}^{N_I} \delta_{S_i} \left(\Delta x'_{n.p._2} + K_1 K_2 K_3\right)_i\right] \quad \text{(Equation 3.3.2-a)}$$

$$= (52.0)(0.00256)(0.575) = 0.077 \text{ in.}$$

The calculated value of $\Delta x_{n.p._2}$ is summed with $\Delta x_{n.p._1}$ and $\Delta x_{n.p._3}$ (computed in Sections 3.3.1 and 3.3.3, respectively) in the Sample Problem of Section 3.3.4 to obtain the total shift in neutral point.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The expected accuracy of the method is less than that in the subsonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range up to a Mach number of 1.6 to 2.0 as indicated in Table 3.3-A. The maximum Mach number provided in the figures should indicate the level to which the method is substantiated. Caution should be used when extrapolating the data beyond the Mach-number range provided in the figures.

3.3.3 NEUTRAL-POINT SHIFT DUE TO CHANGE IN TAIL EFFECTIVENESS

A method is presented in this section for estimating the neutral-point shift due to the change in horizontal-tail effectiveness caused by wing-mounted external-store installations. The method predicts a neutral-point shift due to all installations (armament stations) on the aircraft.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.3-A. The user is cautioned that the neutral-point shift predicted by this method should be considered as only a first approximation because of the limited data base used in deriving the method. Since the method was developed from F-4 and A-7 aircraft wind-tunnel data, special care should be taken when applying the method to aircraft with horizontal-tail spans and vertical locations substantially different from these aircraft. Additional limitations pertaining to the method are listed below:

1. The method has been verified for the Mach-number range indicated in the figures associated with the method. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.

2. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

3. The method is applicable for sideslip angles less than 4^{o}.

The effect due to a pair of symmetrical installations can be computed by doubling the effect of one side.

A. SUBSONIC

DATCOM METHOD

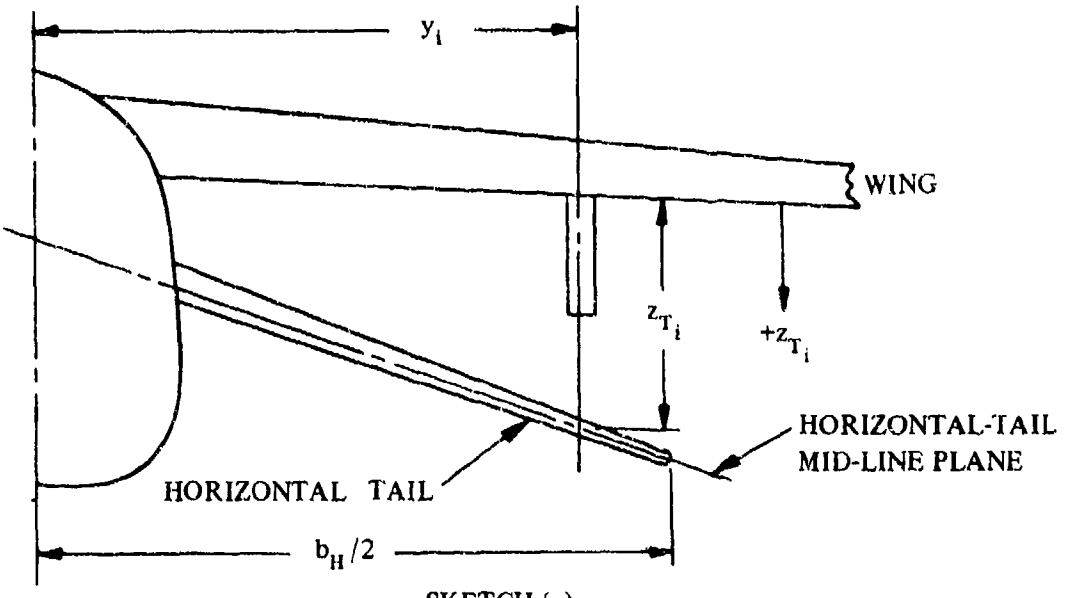
The neutral-point shift in inches, positive for aft shift, due to the change in tail effectiveness from store installations is given by

$$\Delta x_{n.p._3} = \sum_{i=1}^{N_I} \left(\Delta x'_{n.p._3}\right)_i K_{y_i} K_{z_i} \qquad 3.3.3\text{-a}$$

where

N_I is the total number of store installations on the aircraft.

$\Delta x'_{n.p._3}$ is the neutral-point horizontal-tail term obtained from Figures 3.3.3-5a and -5b as a function of configuration and Mach number. For fuselage mounted store installations $\Delta x'_{n.p._3} = 0$.



SKETCH (a)

K_{y_i} is the horizontal-tail span-location factor obtained from Figure 3.3.3-6a as a function of $\frac{y_i}{b_H/2}$ where

y_i is the spanwise distance from the fuselage centerline to the location of installation i (illustrated in Sketch (a)).

b_H is the horizontal-tail span (illustrated in Sketch (a)).

K_{z_i} is the horizontal-tail vertical-location factor obtained from Figure 3.3.3-6b as a function of $\frac{z_{T_i}}{b_H/2}$ where

z_{T_i} is the vertical distance from the wing lower surface at installation i to the horizontal-tail mid-line plane (illustrated in Sketch (a)).

Sample Problem

Given: A swept-wing subsonic-fighter aircraft from Reference 2 described in the Sample Problem of Paragraph A of Section 3.3.1. (See Pages 3.3.1-9 and 3.3.1-10 for identification of store installations.)

Additional Data:

$y_1 = y_5 = 113.75$ in.. $y_2 = y_4 = 78.8$ in. $b_H/2 = 68$ in. $M = 0.6$

$z_{T_1} = z_{T_5} = -59.8$ in. $z_{T_2} = z_{T_4} = -59.8$ in.

Compute:

Expand Equation 3.3.3-a to identify the terms that need to be computed, recalling that the wing installations are symmetrically loaded. Installation 3 is a fuselage mounted installation and the contribution of that installation is zero.

$$\Delta x_{n.p._3} = 2\left(\Delta x'_{n.p._3}\right)_1 K_{y_1} K_{z_1} + 2\left(\Delta x'_{n.p._3}\right)_2 K_{y_2} K_{z_2}$$

$\left(\Delta x'_{n.p._3}\right)_1 = 0.48$ (Figure 3.3.3-5a, single carriage)

$\left(\Delta x'_{n.p._3}\right)_2 = 0.80$ (Figure 3.3.3-5b, multiple carriage)

$$\frac{y_1}{b_H/2} = \frac{113.75}{68} = 1.67$$

$$\frac{z_{T_1}}{b_H/2} = \frac{-59.8}{68} = -0.88$$

$$\frac{y_2}{b_H/2} = \frac{78.8}{68} = 1.16$$

$$\frac{z_{T_2}}{b_H/2} = \frac{-59.8}{68} = -0.88$$

$K_{y_2} = 0.57$ (Figure 3.3.3-6a)

Referring to Figure 3.3.3-6a it is seen that $y_i/(b_H/2)$ is beyond the range of the design chart. This suggests that if the store installation is far enough outboard of the tip of the horizontal tail, the increment in neutral-point shift due to that particular installation is negligible. Therefore, for this configuration it is assumed that $K_{y_1} = 0$.

Referring to Figure 3.3.3-6b it is seen that $z_{T_i}/(b_H/2)$ for both Installations 1 and 2 are well beyond the range of the design chart. It seems reasonable to assume that the value of K_{z_i} will asymptotically approach zero as the vertical distance between the store installation and the horizontal tail is increased. Therefore, for this configuration it is assumed that $K_{z_1} = K_{z_2} = 0$.

Solution:

$$\Delta x_{n.p._3} = \sum_{i=1}^{N_I} \left(\Delta x'_{n.p._3}\right)_i K_{y_i} K_{z_i} \qquad \text{(Equation 3.3.3-a)}$$

$$= 2\left(\Delta x'_{n.p._3}\right)_1 \; K_{y_1} K_{z_1} + 2\left(\Delta x'_{n.p._3}\right)_2 \; K_{y_2} K_{z_2}$$

$$= 2(0.48)(0)(0) + 2(0.80)(0.57)(0)$$

$$= 0$$

The calculated value of $\Delta x_{n.p._3}$ is summed with $\Delta x_{n.p._1}$ and $\Delta x_{n.p._2}$ (computed in Sections 3.3.1 and 3.3.2 respectively) in the Sample Problem of Section 3.3.4 to obtain the total shift in neutral point.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range up to a Mach number of 1.6 to 2.0 as indicated in Table 3.3-A. The maximum Mach number provided in the figures should indicate the level to which the method is substantiated. Caution should be used when extrapolating the data beyond the Mach-number range provided in the figures.

3.3.4 TOTAL NEUTRAL-POINT SHIFT DUE TO EXTERNAL STORES

A method is presented in this section for estimating the total shift in aircraft neutral point due to external-store installations. The method predicts the neutral-point shift for symmetric, asymmetric, and multiple-installation loading configurations.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is applicable to aircraft of conventional design and essentially symmetrical store shapes with no major shape protuberances. The limitations on configuration and Mach-number range are summarized in Table 3.3-A. Additional limitations and assumptions pertaining to the method are listed below:

1. The method is not applicable to wing-tip or wing-tangent-mounted stores.
2. Fuselage-mounted installations must be located on the fuselage centerline.
3. The method is not applicable to empty multiple racks.
4. The effect of empty pylons on neutral point is considered to be negligible.
5. The method has been verified for the Mach-number range given in Table 3.3-A. Caution should be used in extrapolating the empirical curves beyond the given Mach-number range.
6. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.
7. The method gives the best results for an angle-of-attack range from 0 to 8^{o}, although the method can be used for higher angles of attack.
8. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.
9. The method is applicable for sideslip angles less than 4^{o}.

The procedure for computing the total neutral-point shift requires calculation of increments due to lift transfer from stores to aircraft, interference effects on the wing flow field, and change in tail effectiveness. These increments are computed by the methods of Sections 3.3.1, 3.3.2, and 3.3.3, respectively. The increments are computed for the entire loading configuration and then summed by the method of this section to obtain the total increment.

A. SUBSONIC

DATCOM METHOD

The total neutral-point shift in inches, positive for aft shift, due to external-store installations is given by

$$\Delta x_{n.p.} = \Delta x_{n.p._1} + \Delta x_{n.p._2} + \Delta x_{n.p._3} \qquad 3.3.4\text{-a}$$

where

$\Delta x_{n.p._1}$ is the shift in neutral point due to lift transfer from the stores to the clean aircraft (in.), obtained from Section 3.3.1.

$\Delta x_{n.p._2}$ is the shift in neutral point due to the interference effects on the wing flow field (in.), obtained from Section 3.3.2.

$\Delta x_{n.p._3}$ is the shift in neutral point due to the change in tail effectiveness caused by external stores (in.), obtained from Section 3.3.3.

Reference 1 states that the prediction accuracies are such that the predicted values of neutral-point shift are nominally within about 1 inch of the test values 60 percent of the time, and within 4 inches 92 percent of the time.

Sample Problem

Given: A swept-wing subsonic-fighter aircraft from Reference 2 loaded with external-store installations described in the Sample Problem of Paragraph A of Section 3.3.1.

Compute:

$\Delta x_{n.p._1} = -0.114$ in. (Sample Problem, Paragraph A, Section 3.3.1)

$\Delta x_{n.p._2} = 0.077$ in. (Sample Problem, Paragraph A, Section 3.3.2)

$\Delta x_{n.p._3} = 0$ (Sample Problem, Paragraph A, Section 3.3.3)

$\Delta x_{n.p.} = \Delta x_{n.p._1} + \Delta x_{n.p._2} + \Delta x_{n.p._3}$ (Equation 3.3.4-a)

$= -0.114 + 0.077 + 0 = -0.037$ in.

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The expected accuracy of the method is less than that in the subsonic speed range.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range. The expected accuracy of the method is less than that in the subsonic speed range.

3.4 EFFECTS OF EXTERNAL STORES ON AIRCRAFT SIDE FORCE

A method is presented in this section for estimating the increment in aircraft side force due to external-store installations. The method predicts an incremental change in the side-force-due-to-sideslip derivative, ΔC_{Y_β}, which can be added to the clean aircraft C_{Y_β} to obtain the aircraft-with-stores C_{Y_β}.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method is limited to the store-loading configurations and Mach-number range presented in Table 3.4-A.

TABLE 3.4-A

LOADING AND MACH-NUMBER LIMITATIONS

Mounting Location	Carriage Mode	Mount/Loading Type	Mach-Number Range
Wing	Single	Pylon – Empty	0.6 → 2.0
		Pylon – Store	
	Multiple	Pylon – Empty MER	0.6 → 1.6
		Pylon – Fully Loaded MER	
		Pylon – Empty TER	
		Pylon – Fully Loaded TER	
Fuselage	Single	Tangent	0.6 → 2.0
		Pylon – Empty	
		Pylon – Store	
	Multiple	Tangent – Empty MER	0.6 → 1.6
		Tangent – Fully Loaded MER	
		Tangent – Empty TER	
		Tangent – Fully Loaded TER	
		Pylon – Empty MER	
		Pylon – Fully Loaded MER	
		Pylon – Empty TER	
		Pylon – Fully Loaded TER	

The Datcom Method is applicable to mixed-loading configurations obtained by combining two or more loadings specified in Table 3.4-A. The method was developed from symmetrically-loaded-stores data and is therefore limited primarily to symmetrically-loaded configurations. However, certain asymmetric configurations may be treated by the method. It should be noted that one-half of the incremental side force due to a symmetrical-store loading is not necessarily equivalent to the side force produced by half of that loading carried asymmetrically. Where there are aircraft components near the stores, or if strong lateral flow fields exist due to angle of attack, part of the aerodynamic side force induced by an installation on one side of the aircraft is cancelled by an opposite force on the other side. The Datcom Method is considered applicable to asymmetric configurations for which the sidewash change due to angle of attack is zero and fuselage effects are negligible.

The prediction method was developed from data based on an angle of attack of 5^{o}. No method is provided to account for the effect of angle-of-attack change on side force, but the method is considered to be valid throughout the normal cruise angle-of-attack range.

The method is subject to the following additional limitations and assumptions:

1. The method has been verified for the Mach-number ranges given in Table 3.4-A. Caution should be used in extrapolating the empirical curves beyond the given Mach-number ranges.

2. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

3. The store shape is essentially symmetrical with no major shape protuberances.

4. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

5. No tail effects are included.

6. The method is applicable for sideslip angles less than 8^{o}.

The side-force-derivative increment is composed of a basic contribution due to the store installations and a contribution due to interference between adjacent installations (when separation distance is sufficiently small).

A. SUBSONIC

DATCOM METHOD

The increment in C_{Y_β}, based on wing reference area, due to external-store installations is given by

$$\Delta C_{Y_\beta} = \frac{1}{S_W}\left[\sum_{i=1}^{N_I} \frac{1}{2}\left(Y_{B_\beta}\right)_i + \sum_{j=1}^{N_P}\left(Y_{A_\beta}\right)_j\right] \qquad 3.4\text{-a}$$

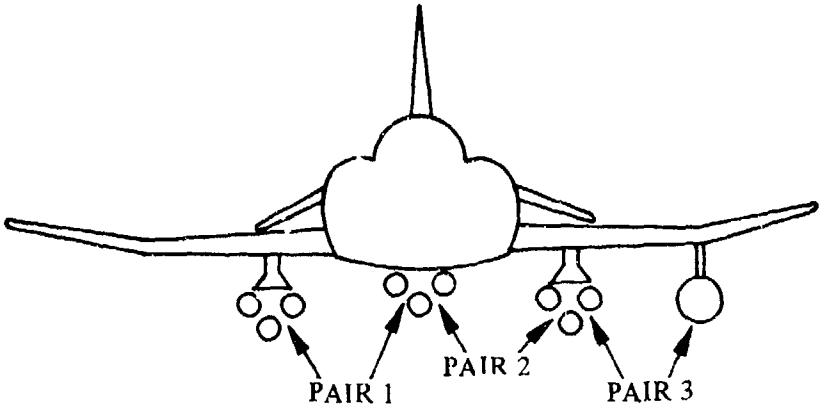
where

S_W is the wing reference area (ft^2).

N_I is the total number of store installations.

N_P is the total number of pairs of adjacent-store installations carried. (See Sketch (a).)

Y_{B_β} is the basic side-force contribution (ft^2/deg) per degree sideslip due to a symmetrical pair of external-store installations, calculated in Step 1 below. Since the empirical equations and figures for Y_{B_β} are based on a pair of symmetrical-store installations, Y_{B_β} must be divided by 2 before summing over the total number of installations, thus allowing for the inclusion of asymmetrical loading cases.



SKETCH (a)

Y_{A_β} is the side-force contribution (ft^2/deg) per degree sideslip due to interference effects from a pair of adjacent external-store installations, calculated in Step 2 below.

ΔC_{Y_β} is computed by using the following steps:

1. Compute Y_{B_β} for each installation.
2. Compute Y_{A_β} for each pair of adjacent installations.
3. Compute ΔC_{Y_β}.

Step 1. Compute Y_{B_β} for each installation:

The various loading configurations are assigned reference numbers in Table 3.4-B.

TABLE 3.4-B

CONFIGURATION SUMMARY

Mounting \ Carriage	Empty	Single	Empty MER	Full MER	Empty TER	Full TER
Wing-Pylon	1	2	3	4	5	6
Fuselage-Tangent	–	7	8	9	10	11
Fuselage-Pylon	12	13	14	15	16	17

$$Y_{B_\beta} = -(B_P + B_R + B_N + B_X + B_Y)\, K_M \qquad 3.4\text{-b}$$

where

B_P is the pylon contribution given by

$$B_P = \frac{K_{PC}\, h_p^{\,2}}{144} \qquad 3.4\text{-c}$$

where

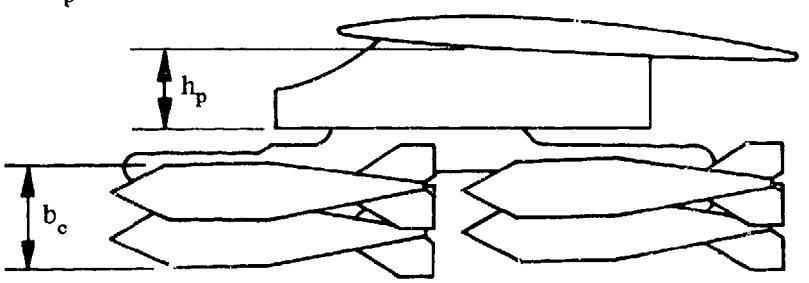
K_{PC} is a pylon constant obtained from Table 3.4-C.

TABLE 3.4-C

PYLON CONSTANT

Configuration	1	2	3	4	5	6	7-11	12	13	14	15	16	17
K_{PC}	.10	.15	.14	.14	.12	.12	0	.10	.15	.14	.14	.12	.12

h_p is the average pylon height (in.). (See Sketch (b).)



SKETCH (b)

B_R is the rack contribution.

For Configurations 2, 7, and 13 the store contribution is included and

$$B_R = K_F \frac{b_F^2}{144} + \frac{(0.09)\, d_S^2}{144} \qquad 3.4\text{-d}$$

where

K_F is a fin constant given by

K_F = 0.082 for + and X fins

K_F = 0.107 for V fins

b_F is the store-fin span (in.). (Total span measured tip-to-tip. For V fins, the total span of the actual fin and its mirror image.)

d_S is the store maximum diameter (in.).

For other configurations, B_R is given by Table 3.4-D.

TABLE 3.4-D

RACK CONTRIBUTION

Configuration	1	3	4	5	6	8	9	10	11	12	14	15	16	17
B_R	0	.325	.325	.183	.183	.325	.325	.183	.183	0	.325	.325	.183	.183

B_N is the store contribution

For Configurations 1, 3, 5, 8, 10, 12, 14, and 16 $B_N = 0$.

For single-store installations (Configurations 2, 7, and 13), B_N is included in the B_R computation.

For Configurations 4, 6, 9, 11, 15, 17

$$B_N = 0.0666 \left(\frac{b_c}{12}\right)^2 \left(\frac{b_F}{d_S}\right)^3 (R_D + 1) \qquad 3.4\text{-e}$$

where

b_c is the maximum vertical span (in.) of the side projection of the store cluster in a vertical plane, excluding protruding fins. (See Sketch (b).)

R_D is a correlation factor given by Figure 3.4-12 for Configurations 4, 9, and 15. $R_D = 0$ for Configurations 6, 11, and 17. All other terms in Equation 3.4-e have been previously defined.

B_X is the contribution due to pylon longitudinal location.

For fuselage-mounted configurations (Configurations 7-17) $B_X = 0$.

For wing-pylon-mounted configurations (Configurations 1-6), B_X is given by

$$B_X = (B_P + B_R + B_N)(K_{XP} - 1) \qquad 3.4\text{-f}$$

where B_P, B_R, B_N were previously defined and

$$K_{XP} = (1 + A_2)(A_1) \left(\begin{array}{c} K_{XP} \text{ has a maximum} \\ \text{value of 1.0} \end{array}\right) \qquad 3.4\text{-g}$$

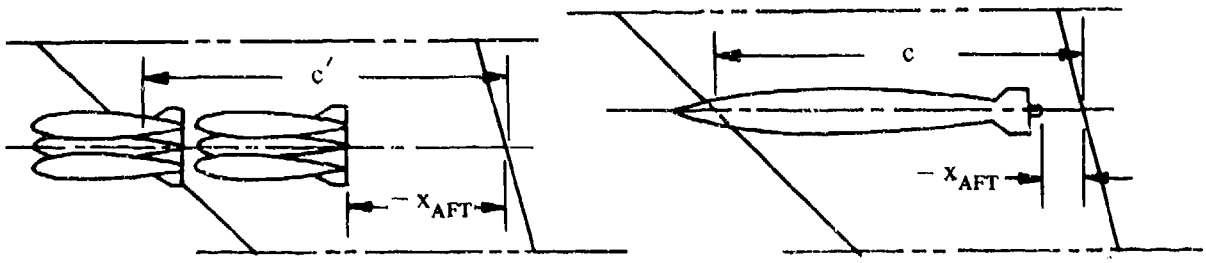
where

A_2 is a store-size correlation factor obtained from Figure 3.4-13 as a function of the maximum store diameter, d_S. For Configurations 1, 3, and 5, the value of A_2 is zero.

A_1 is a longitudinal-location correlation factor obtained from Figure 3.4-14 as a function of x_{AFT}/c where

x_{AFT} is the longitudinal distance (in.) from the local wing trailing edge to the trailing edge of pylon, rack, or store as appropriate (i.e., the most aft component), positive in the aft direction. (See Sketch (c).)

c is the local wing chord at the store installation (in.). (See Sketch (c).)



MULTIPLE STORES SINGLE STORE

SKETCH (c)

B_Y is the contribution due to spanwise location of the pylon installation.

For fuselage-mounted configurations (Configurations 7-17),

$$B_Y = 0 \qquad 3.4\text{-h}$$

For wing-pylon-mounted configurations (Configurations 1-6) on low-wing aircraft,

$$B_Y = K_y \left(\frac{y_i}{b_W/2} - 0.350 \right) \qquad 3.4\text{-i}$$

For wing-pylon-mounted configurations on high-wing aircraft,

$$B_Y = K_y \left(\frac{y_i'}{b_e/2} - 0.350 \right) \qquad 3.4\text{-j}$$

where

K_y is a store-installation-depth factor obtained from Figure 3.4-15 as a function of z, the maximum depth (in.) of the store installation.

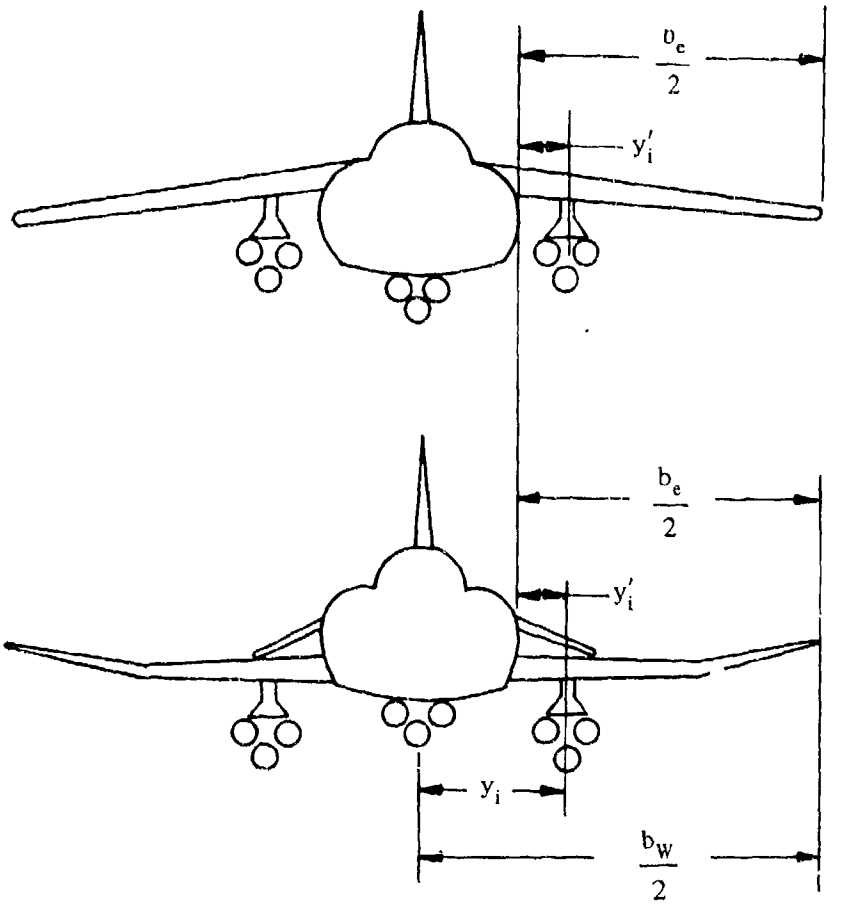
y_i is the spanwise distance from the fuselage centerline to the location of installation i (illustrated in Sketch (d)).

b_W is the wing span.

y_i' is the spanwise distance from the outboard edge of the fuselage to the location of installation i (illustrated in Sketch (d)).

b_e is the exposed wing span (illustrated in Sketch (d)).

K_M is a side-force Mach-effect factor obtained from Figure 3.4-16 as a function of Mach number and $\frac{y_i'}{b/2}$ where $b = b_W$ for low-wing aircraft, $b = b_e$ for high-wing aircraft, and y_i', b_W, and b_e were previously defined.



SKETCH (d)

Step 2. Compute Y_{A_β} for each pair of adjacent installations.

Determine the number of pairs of adjacent installations (see Sketch (a)).

Compute Y_{A_β} for each adjacent pair:

$$Y_{A_\beta} = -\left[\left(Y_{B_\beta}\right)_1 + \left(Y_{B_\beta}\right)_2\right] R_{NEG} \qquad 3.4\text{-k}$$

where

$\left(Y_{B_\beta}\right)_1$ is obtained from Equation 3.4-b for the first of the pair of installations.

$\left(Y_{B_\beta}\right)_2$ is obtained from Equation 3.4-b for the second of the pair of installations.

R_{NEG} is an adjacent-store interference factor obtained from Figure 3.4-17 as a function of $(X_F + X_A)/(\ell_1 + \ell_2)$ and Mach number where

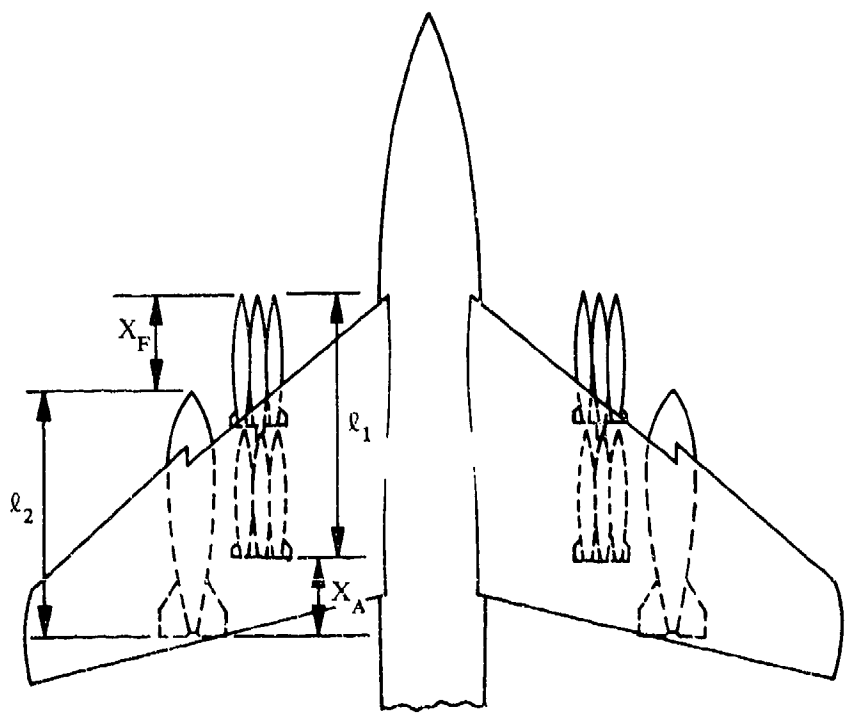
X_F is the absolute longitudinal distance from the nose of one store installation to the nose of the adjacent installation. (See Sketch (e).)

X_A is the absolute longitudinal distance from the trailing edge of one store installation to the trailing edge of the adjacent installation. (See Sketch (e).)

ℓ_1 and ℓ_2 are the lengths of the two store installations. (See Sketch e).)

For no adjacent store installations,

$$Y_{A_\beta} = 0 \qquad 3.4\text{-}\ell$$



SKETCH (e)

Step 3. Compute ΔC_{Y_β}

ΔC_{Y_β} is computed from Equation 3.4-a by summing the Y_{B_β} values obtained in Step 1 for each installation and the Y_{A_β} values obtained from Step 2 for each pair of adjacent installations.

Reference 1 states that the method nominally results in prediction errors of 10 to 15 percent. A comparison of test data with results calculated by this method is provided in Table 3.4E. Additional comparisons of test and calculated results are found in Reference 1.

Sample Problem

Given: A swept-wing subsonic-fighter aircraft from Reference 2 with one 300-gal tank, pylon mounted on each wing.

Aircraft Data:

$S_W = 260\ ft^2$ Low-wing configuration

Store Data:

$d_S = 26.5$ in. $b_F = 35.06$ in. + type fins

Installation Data:

$h_p = 11.2$ in. $\frac{y_1}{b_W/2} = 0.320$ $\frac{x_{AFT}}{c} = 0.288$ $z = 37.3$ in.

Additional Data:

$M = 0.6$

Compute:

Step 1. Compute Y_{B_β} for each installation. (Since the installations are symmetrical, only one side need be computed). This is Configuration 2 (Table 3.4-B)

$K_{PC} = 0.15$ (Table 3.4-C)

$$B_P = \frac{K_{PC}\, h_P^{\,2}}{144} = \frac{(0.15)(11.2)^2}{144} = 0.1307 \qquad \text{(Equation 3.4-c)}$$

$K_F = 0.082$ (+ type fins)

$$B_R = K_F \frac{b_F^{\,2}}{144} + \frac{(0.09) d_S^{\,2}}{144} \qquad \text{(Equation 3.4-d)}$$

$$= \frac{(0.082)(35.06)^2}{144} + \frac{(0.09)(26.5)^2}{144}$$

$= 1.1389$

B_N is included in the B_R computation (Configuration 2)

$A_2 = 0.365$ (Figure 3.4-13)

$A_1 = 0.77$ (Figure 3.4-14, single store)

$K_{XP} = (1 + A_2)(A_1)$ (maximum value of 1.0) (Equation 3.4-g)

$= (1 + 0.365)(0.77) = 1.05$; use $K_{XP} = 1.0$

$B_X = (B_P + B_R + B_N)(K_{XP} - 1)$ (Equation 3.4-f)

$= (0.1307 + 1.1389 + 0)(1.0 - 1)$

$= 0$

$K_Y = 1.95$ (Figure 3.4-15)

$B_Y = K_Y \left(\frac{y_i}{b_W/2} - 0.350\right)$ (Equation 3.4-i)

$= 1.95\,(0.320 - 0.350) = -0.0585$

$K_M = 1.0$ (Figure 3.4-16)

$Y_{B_\beta} = -(B_P + B_R + B_N + B_X + B_Y)K_M$ (Equation 3.4-b)

$= -(0.137 + 1.1389 + 0 - 0 - 0.0585)(1.0)$

$= -1.211$

Step 2. Compute Y_{A_β} for each pair of adjacent installations. In this case there are no adjacent installations, and $Y_{A_\beta} = 0$.

Step 3. Compute ΔC_{Y_β}:

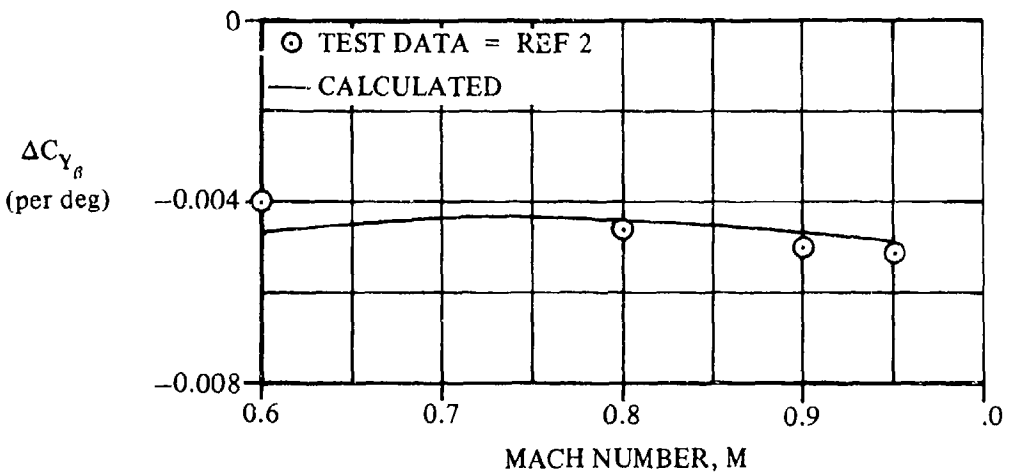
$$\Delta C_{Y_\beta} = \frac{1}{S_W}\left[\sum_{i=1}^{N_I} \frac{1}{2}\left(Y_{B_\beta}\right)_i + \sum_{j=1}^{N_P}\left(Y_{A_\beta}\right)_j\right] \quad \text{(Equation 3.4-a)}$$

$$= \frac{1}{S_W}\left[\sum_{i=1}^{2} \frac{1}{2}\left(Y_{B_\beta}\right)_i + 0\right]$$

$$= \frac{1}{260}\left[\frac{1}{2}(-1.211) + \frac{1}{2}(-1.211)\right]$$

$= -0.0047$ per deg

Values of ΔC_{Y_β} at other Mach numbers have been calculated and are shown in comparison to test data from Reference 2 in Sketch (c).



SKETCH (c)

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The user is cautioned that the expected accuracy of the method is less than that expected in the subsonic speed range. A comparison of test data with results calculated by this method at transonic speed is presented in Table 3.4-E.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range up to a Mach number of 1.6 to 2.0 as indicated in Table 3.4-A. The maximum Mach number provided in the figures should indicate the level to which the method is substantiated by Reference 1. Caution should be used when extrapolating the data beyond the Mach-number range provided in the figures. A comparison of test data with results calculated by this method at supersonic speeds is presented in Table 3.4-E.

3.5 EFFECT OF EXTERNAL STORES ON AIRCRAFT YAWING MOMENT

A method is presented in this section for estimating the increment in aircraft yawing moment due to external-store installations. For symmetrically-loaded configurations, the increment is primarily due to sideslip. The incremental yawing moment due to asymmetrical loading is composed of a moment due to sideslip and a moment due to drag differential. The moment due to drag differential can be estimated by multiplying the incremental drag coefficient due to the store installation (which may be computed from Section 3.2) by the moment arm from the c.g. to the spanwise location of the installation. The method presented in this section predicts an incremental change in the yawing-moment-due-to-sideslip derivative, ΔC_{n_β}, which can be added to the clean aircraft C_{n_β} to obtain the aircraft-with-stores C_{n_β}.

The Datcom Method is taken from Reference 1 and is empirical in nature. The method requires that the incremental side-force data be provided by the user or computed by the method of Section 3.4. The method is limited to the store-loading configurations and Mach-number ranges presented in Table 3.5-A.

The Datcom Method is applicable to mixed loading configurations obtained by combining two or more loadings specified in Table 3.5-A. The method was developed from symmetrically-loaded-stores data and is therefore limited primarily to symmetrically-loaded configurations. However, certain asymmetric configurations can be treated by the method.

The prediction method was developed from data based on an angle of attack of 5^o. No method is provided to account for the effect of angle-of-attack change on yawing moment, but the method is considered to be valid throughout the normal cruise angle-of-attack range.

TABLE 3.5-A

LOADING AND MACH-NUMBER LIMITATIONS

Mounting Location	Carriage Mode	Mount/Loading	Mach-Number Range
Wing	Single	Pylon – Empty	0.6 → 2.0
		Pylon – Store	
	Multiple	Pylon – Fully-Loaded MER	0.6 → 1.6
		Pylon – Fully-Loaded TER	
Fuselage	Single	Tangent	0.6 → 2.0
		Pylon – Store	
	Multiple	Pylon – Fully-Loaded MER	0.6 → 1.6

The method is subject to the following additional general limitations and assumptions:

1. The method has been verified for the Mach-number ranges given in Table 3.5-A. Caution should be used in extrapolating the empirical curves beyond the given Mach-number ranges.

2. The method has not been verified for configurations in which flaps, slats, or other flow-disrupting devices are deployed.

3. The store shape is essentially symmetrical with no major shape protuberances.

4. The data base used in deriving the method relied heavily on swept-wing tactical-combat-aircraft wind-tunnel data.

5. No tail effects are included.

6. The method is applicable for sideslip angles less than 8^{o}.

The method is based on the premise that yawing moment is the product of the side force and a moment arm from the point of force application to a reference point. Lift and drag effects are neglected. The method is applicable to asymmetric configurations for which the sidewash change due to angle of attack is zero and fuselage effects are negligible.

The yawing-moment-derivative increment is composed of a basic contribution due to the store installations and a contribution due to interference between adjacent installations (when separation distance is small).

A. SUBSONIC

DATCOM METHOD

The increment in C_{n_β} (based on wing reference area and span) due to external stores is given by

$$\Delta C_{n_\beta} = \frac{1}{S_W b_W} \left\{ \sum_{i=1}^{N_I} \left(\frac{1}{2} Y_{B_\beta} \frac{\ell_m}{12} \right)_i + \sum_{j=1}^{N_P} \left[\frac{1}{2} Y_{A_\beta} \left(\frac{\ell_{m_1}}{12} + \frac{\ell_{m_2}}{12} \right) \right]_j \right\} \qquad 3.5\text{-a}$$

where

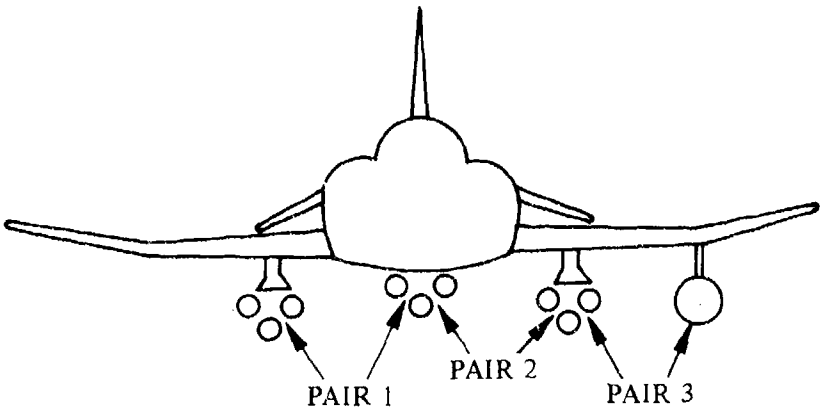
S_W is the wing reference area (ft^2).

b_W is the wing span (ft).

N_I is the total number of store installations on the aircraft.

Y_{B_β} is the basic side-force contribution (ft^2/deg) per degree sideslip due to a symmetrical pair of external-store installations, obtained from Section 3.4.

N_P is the total number of pairs of adjacent-store installations carried. (See Sketch (a).)



SKETCH (a)

Y_{A_β} is the side-force contribution (ft^2/deg) per degree sideslip due to interference effects from a pair of adjacent-external store installations, obtained from Section 3.4. This term should only be used for single-store installations placed at approximately equal distances below the wing, with minimum lateral separation of 25 to 60 inches between store surfaces of adjacent installations.

ℓ_m, ℓ_{m_1}, ℓ_{m_2} are moment arms (in.) from the moment reference point to the effective point of application of the side-force increment due to external stores, positive in the aft direction. The moment arm for the first of the pair of adjacent installations is ℓ_{m_1}, the second of the pair is ℓ_{m_2}. The value of ℓ_m is given by

$$\ell_m = (FS)_{ref} - [(FS)_{LE} + \ell_x] \qquad 3.5\text{-b}$$

where

$(FS)_{ref}$ is the fuselage station (in.) of the moment reference point.

$(FS)_{LE}$ is the fuselage station (in.) of the nose of the most forward store on the installation or the leading edge of the pylon for the empty pylon case.

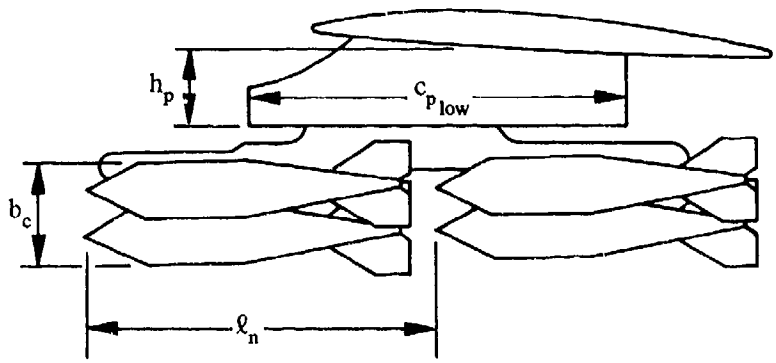
ℓ_x is the longitudinal distance (in.) from $(FS)_{LE}$ to the point of side-force application, positive aft. This term is a function of installation type, and is calculated below for various configurations.

Case 1: Wing-Mounted Empty Pylon

$$\ell_x = 0.25\, c_{p_{low}} \qquad 3.5\text{-c}$$

where

$c_{p_{low}}$ is the bottom-pylon-chord length (in.). (See Sketch (b).)



SKETCH (b)

Case 2: Wing- or Fuselage-Pylon-Mounted Single Store

$$\ell_x = \frac{\ell_P B_P + \ell_{SB} B_{SB} + \ell_{SF} B_{SF}}{B_P + B_{SB} + B_{SF}} \qquad 3.5\text{-d}$$

where

ℓ_P is the pylon moment arm (in.) given by

$$\ell_P = 0.25\, c_{p_{low}} \qquad 3.5\text{-e}$$

where $c_{p_{low}}$ is defined above for Case 1.

B_P is the pylon contribution given by

$$B_P = 0.15 \left(\frac{h_p}{12}\right)^2 \qquad 3.5\text{-f}$$

where

h_p is the average pylon height (in.) shown in Sketch (b).

ℓ_{SB} is the store-body moment arm (in.) given by

$$\ell_{SB} = 0.15\, \ell_S \qquad 3.5\text{-g}$$

where

ℓ_S is the store-body length (in.).

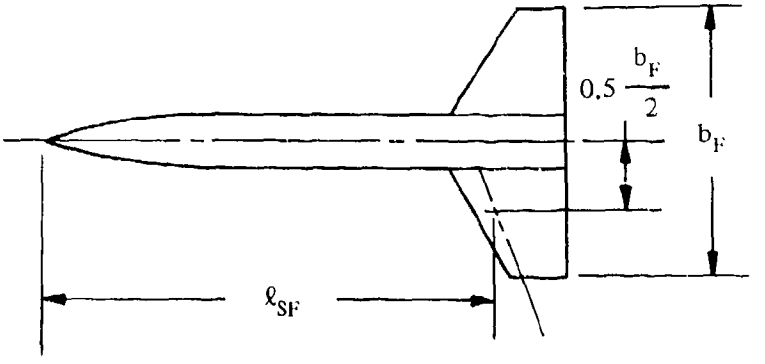
B_{SB} is the store-body contribution given by

$$B_{SB} = 0.09\left(\frac{d_S}{12}\right)^2 \qquad 3.5\text{-h}$$

where

d_S is the maximum store diameter (in.).

ℓ_{SF} is the longitudinal distance (in.) from the store nose to the intersection of the store-fin quarter chord and the store-fin 50-percent semispan. (See Sketch (c).)



SKETCH (c)

B_{SF} is the store-fin contribution given by

$$B_{SF} = 0.082\left(\frac{b_F}{12}\right)^2 \quad \text{for + or x type fins} \qquad 3.5\text{-i}$$

or

$$B_{SF} = 0.107\left(\frac{b_F}{12}\right)^2 \quad \text{for V type fins} \qquad 3.5\text{-j}$$

where

b_F is the store-fin span (ft) shown in Sketch (c). (For V fins, the total span of the actual fin and its mirror image.)

Case 3: Wing- or Fuselage-Pylon-Mounted Fully-Loaded MER

$$\ell_x = \frac{(0.933)\,\ell_P B_P + 0.5\,\ell_{EM}\,(0.0325) + 0.5\,\ell_S B_{FSC} + \ell_{ASC} B_{ASC}}{B_P + 0.325 + B_{FSC} + B_{ASC}} \qquad 3.5\text{-k}$$

where

ℓ_P is given by Equation 3.5-e.

B_P is given by Equation 3.5-f.

ℓ_{EM} is the length of the empty MER (in.).

ℓ_S is the store-body length (in.).

B_{FSC} is the forward-store-cluster contribution given by

$$B_{FSC} = 0.0666 \left(\frac{b_c}{12}\right)^2 \left(\frac{b_f}{d_S}\right)^2 \qquad 3.5\text{-}\ell$$

where

b_c is the maximum vertical span (in.) of the side projection of the store cluster in a vertical plane, excluding protruding fins. (See Sketch (b).)

b_F and d_S are defined above in Case 2.

ℓ_{ASC} is the aft-store-cluster moment arm given by

$$\ell_{ASC} = 0.5\,\ell_S + \ell_n \qquad 3.5\text{-}m$$

where

ℓ_n is the longitudinal distance (in.) from the store nose of the forward cluster to the store nose of the aft cluster. (See Sketch (b).)

B_{ASC} is the aft-store-cluster contribution given by

$$B_{ASC} = R_{LC} B_{FSC} \qquad 3.5\text{-}n$$

where

B_{FSC} is given by Equation 3.5-ℓ.

R_{LC} is an aft-store-cluster lateral-clearance factor obtained from Figure 3.5-12 as a function of d_S the maximum store diameter.

Case 4: Wing-Pylon-Mounted Fully-Loaded TER

$$\ell_x = \frac{(0.80)\,\ell_P B_P + 0.5\,\ell_{ET}\,(0.182) + 0.5\,\ell_S B_{FSC}}{B_P + 0.182 + B_{FSC}} \qquad 3.5\text{-o}$$

where

ℓ_P is given by Equation 3.5-e.

B_P is given by Equation 3.5-f.

ℓ_{ET} is the length of the empty TER (in.).

B_{FSC} and ℓ_S are defined above in Case 3.

Case 5: Fuselage-Tangent-Mounted Single Store

$$\ell_X = \frac{\ell_{SB} B_{SB} + \ell_{SF} B_{SF}}{B_{SB} + B_{SF}} \qquad 3.5\text{-p}$$

where

ℓ_{SB} is given by Equation 3.5-g.

B_{SB} is given by Equation 3.5-h.

ℓ_{SF} is defined previously in Case 2.

B_{SF} is given by Equations 3.5-i and 3.5-j.

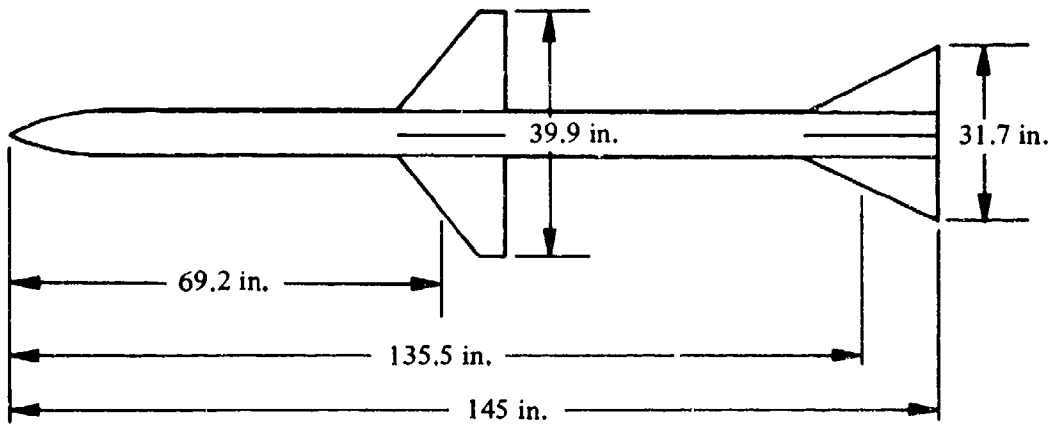
Reference 1 indicates that the method nominally results in average prediction errors of 20 percent from the actual yawing-moment increment. The percent error is highly dependent upon the distance from the aircraft center of gravity to the point of side-force application. When the side force acts through a point near the center of gravity, the percent error may be large even though the moment error is small. A comparison of test data with results calculated by this method is presented in Table 3.5-B. Additional comparisons of test and calculated results are found in Reference 1.

Sample Problem

Given: A swept-wing fighter aircraft from Reference 3 with single pylon-mounted air-to-air missiles mounted on each wing.

Aircraft Data:

$S_W = 530\ ft^2$ $\quad b_W = 38.67\ ft$ $\quad (FS)_{ref} = 317.0\ in.$



Store Data:

d_S = 8 in. $\quad \ell_S$ = 145 in. $\quad b_F$ (FWD) = 39.9 in.

b_F (AFT) = 31.7 in. $\quad \ell_{SF}$ (FWD) = 69.2 in. $\quad \ell_{SF}$ (AFT) = 135.5 in.

Installation Data:

$c_{p_{low}}$ = 113.8 in. $\quad h_p$ = 18 in. $\quad (FS)_{LE}$ = 182.0 in.

Additional Data:

M = 0.6 $\quad \alpha = 5^o$ $\quad \Delta C_{Y_\beta}$ = –0.0015 per deg

Compute:

Find ℓ_x for each installation. (Only one side need be computed since the installations are symmetrical.) For a wing-pylon-mounted single store:

$$\ell_P = 0.25\, c_{p_{low}} = (0.25)(113.8) = 28.45 \text{ in.} \qquad \text{(Equation 3.5-e)}$$

$$B_P = 0.15\left(\frac{h_p}{12}\right)^2 = (0.15)\left(\frac{18}{12}\right)^2 = 0.3375 \qquad \text{(Equation 3.5-f)}$$

$$\ell_{SB} = 0.15\, \ell_S = (0.15)(145) = 21.75 \text{ in.} \qquad \text{(Equation 3-5-g)}$$

$$B_{SB} = 0.09\left(\frac{d_S}{12}\right)^2 = (0.09)\left(\frac{8}{12}\right)^2 = 0.0400 \qquad \text{(Equation 3.5-h)}$$

Since there are two sets of fins on this store, both sets are accounted for in the computation.

For the forward set of fins,

ℓ_{SF} = 69.2 in.

$$B_{SF} = (0.082)\left(\frac{b_F}{12}\right)^2 = (0.082)\left(\frac{39.9}{12}\right)^2 = 0.907 \text{ ft}^2 \qquad \text{(Equation 3.5-i)}$$

For the aft set of fins,

ℓ_{SF} = 135.5 in.

$$B_{SF} = (0.082)\left(\frac{b_F}{12}\right)^2 = (0.082)\left(\frac{31.7}{12}\right)^2 = 0.572 \qquad \text{(Equation 3.5-i)}$$

$$\ell_x = \frac{\ell_P B_P + \ell_{SB} B_{SB} + \ell_{SF} B_{SF}}{B_P + B_{SB} + B_{SF}} \qquad \text{(Equation 3.5-d).}$$

$$= \frac{(28.45)(0.338) + (21.75)(0.0400) + (69.2)(0.907) + (135.5)(0.572)}{0.338 + 0.0400 + 0.907 + 0.572}$$

= 81.2 in.

Find ℓ_m:

$\ell_m = (FS)_{ref} - [(FS)_{LE} + \ell_x]$ (Equation 3.5-b)

= 317.0 − [182.0 + 81.2]

= 53.8 in.

Since there are no pairs of adjacent store installations, ℓ_{m_1} and ℓ_{m_2} are not computed.

Find Y_{B_β} and Y_{A_β}:

Y_{B_β} and Y_{A_β} are estimated by the method of Section 3.4.

Y_{A_β} = 0 (no adjacent store installations)

Since ΔC_{Y_β} is given, Y_{B_β} can be computed from Equation 3.4-a.

$$\Delta C_{Y_\beta} = \frac{1}{S_W}\left[\sum_{i=1}^{N_I} \frac{1}{2}\left(Y_{B_\beta}\right)_i + \sum_{j=1}^{N_P}\left(Y_{A_\beta}\right)_j\right] \qquad \text{(Equation 3.4-a)}$$

Recalling that $Y_{A_\beta} = 0$ and that there are two installations symmetrically placed,

$$\Delta C_{Y_\beta} = \frac{1}{S_W}(2)\left(\frac{1}{2}\right)Y_{B_\beta}$$

$$Y_{B_\beta} = S_W \Delta C_{Y_\beta}$$

$$= (-0.0015)(530)$$

$$= -0.795 \text{ ft}^2/\text{deg}$$

Find ΔC_{n_β}:

$$\Delta C_{n_\beta} = \frac{1}{S_W b_W}\left\{\sum_{i=1}^{N_I}\left(\frac{1}{2} Y_{B_\beta}\frac{\ell_m}{12}\right)_i + \sum_{j=1}^{N_P}\left[\frac{1}{2} Y_{A_\beta}\left(\frac{\ell_{m_1}}{12} + \frac{\ell_{m_2}}{12}\right)\right]_j\right\} \quad \text{(Equation 3.5-a)}$$

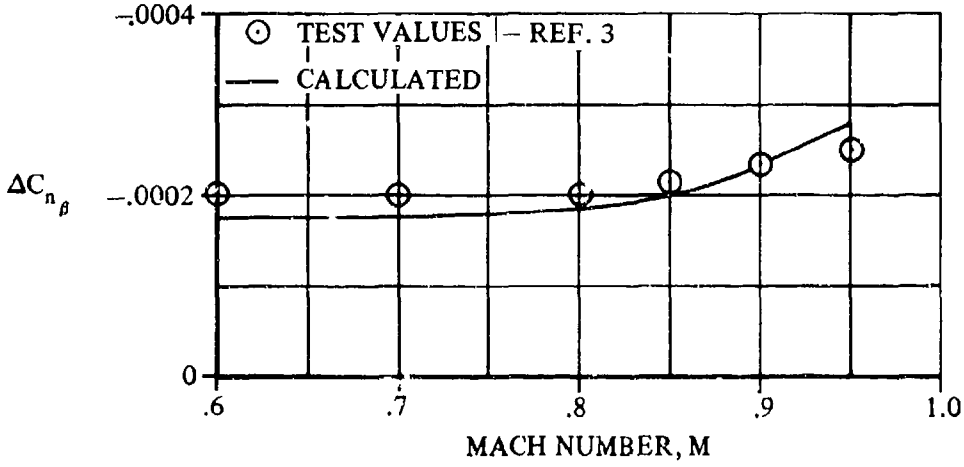
Since $Y_{A_\beta} = 0$, the second term in the above equation drops out. Since the store installations are symmetrical, the above equation reduces to

$$\Delta C_{n_\beta} = (2)\frac{1}{S_W b_W}\left(\frac{1}{2} Y_{B_\beta}\frac{\ell_m}{12}\right)$$

$$= \frac{2}{(530)(38.67)}\frac{1}{2}(-0.795)\left(\frac{53.8}{12}\right)$$

$$= -0.000174 \text{ per deg}$$

Additional values of ΔC_{n_β} at other Mach numbers are shown in comparison to test data from Reference 1 in Sketch (d).



SKETCH (d)

B. TRANSONIC

The method presented in Paragraph A of this section is also valid in the transonic speed range. The user is cautioned that the expected accuracy of the method is less than that expected in the subsonic speed range. A comparison of test data with results calculated by this method at transonic speeds is presented in Table 3.5-B.

C. SUPERSONIC

The method presented in Paragraph A of this section is also valid in the supersonic speed range up to a Mach number of 1.6 to 2.0 as indicated in Table 3.5-A. The maximum Mach numbers provided in the figures of Section 3.4 should indicate the levels to which the method is substantiated by Reference 1. Caution should be used when extrapolating the data beyond the Mach-number range provided in the figures. A comparison of test data with results calculated by this method at supersonic speeds is presented in Table 3.5-B.

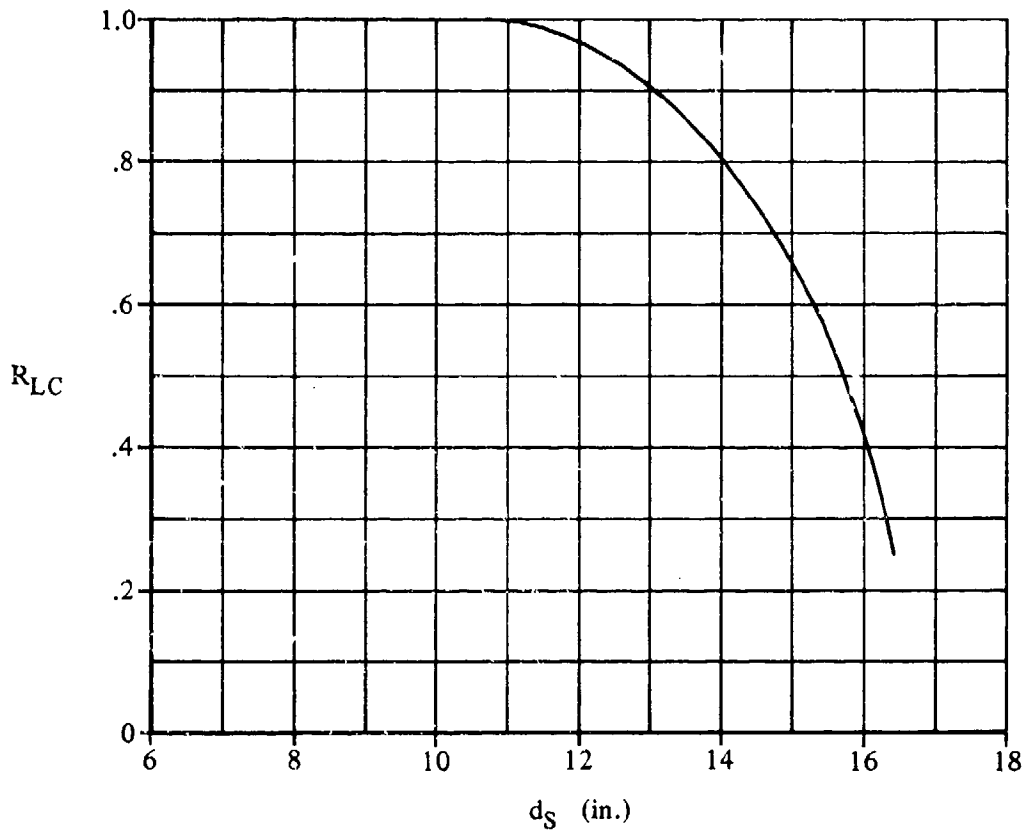

FIGURE 3.5-12 AFT-STORE-CLUSTER LATERAL-CLEARANCE FACTOR

3.6 EFFECT OF EXTERNAL STORES ON AIRCRAFT ROLLING MOMENT

No Datcom Method is provided to estimate the effect of external stores on aircraft rolling moment. No suitable general methods have been developed which provide satisfactory results for a wide range of loading configurations. The user may consult the references cited in Section 3 for available information on prediction of rolling moments.

4.1 WINGS AT ANGLE OF ATTACK

A great deal of theoretical and experimental work has been done toward the development of airfoil sections. Theoretical airfoil design is hampered by the existence of viscous effects in the form of a "boundary layer" of low-energy air between the airfoil surface and the free stream. This boundary layer affects chiefly the section drag and maximum lift characteristics but also has minor effects on lift-curve slope, angle of attack for zero lift, and section pitching-moment coefficient.

Since the boundary layer is influenced by surface roughness, surface curvature, pressure gradient, heat transfer between the surface and the boundary layer, and viscous interaction with the free stream, it is apparent that no simple theoretical considerations can accurately predict all the airfoil characteristics. For these reasons, experimental data are always preferable to theoretical calculations.

Airfoils have been optimized for many specific characteristics, including: high maximum lift, low drag at low lift coefficients, low drag at high lift coefficients, low pitching moments, low drag in the transonic region, and favorable lift characteristics beyond the critical Mach number. Optimization of an airfoil in one direction usually compromises it in another. Thus, low-drag airfoils have poor high-lift characteristics, and high-lift airfoils have low critical Mach numbers.

It is apparent from the above that any generalized charts for airfoil section characteristics, including the ones in this handbook, must be used with caution.

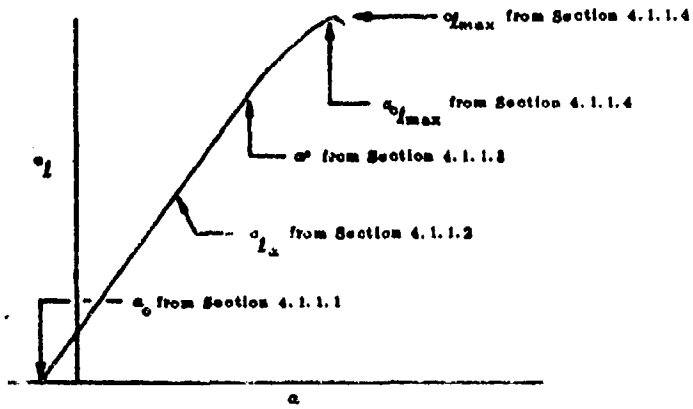
Included in this Section are tabulated NACA experimental and theoretical data that are used and discussed in detail in Sections 4.1.1.1, 4.1.1.2, 4.1.1.3, 4.1.1.4, 4.1.2.1, and 4.1.2.2.

Table 4.1.1-A summarizes experimental data for the NACA four- and five-digit airfoils. Table 4.1.1-B gives corresponding data for the NACA 6-series airfoils. The data, from reference 1, are for smooth-leading-edge conditions and 9×10^6 Reynolds number.

Information is presented on the following airfoil characteristics:

1. angle of attack at zero lift, α_0
2. lift-curve slope, c_{ℓ_α}
3. angle of attack at which the lift curve deviates from linear variation, α^*
4. maximum lift coefficient, $c_{\ell_{max}}$
5. angle of attack for maximum lift coefficient, $\alpha_{c_{\ell_{max}}}$
6. design lift coefficient c_{ℓ_i}
7. angle of attack at design lift coefficient, α_i

From these first five quantities the approximate section lift-curve shape can be synthesized, as illustrated in the following figure:



Experimental data for a large number of additional airfoils are available in the literature. These airfoils may be located with the aid of table 4.1.1-C.

Table 4.1.1-D presents theoretical aerodynamic characteristics of various airfoil mean lines. This theoretical information is used to approximate characteristics of NACA-type airfoils for which experimental data are not available.

0.9	1.0	0.90	-0.225	
1.0	1.0	0	-0.250	

* "Corresponding" cambers are those for which the chordwise position of maximum camber is the same.

** Lift coefficient is based on airfoil chord.

4.1.1.1 SECTION ZERO-LIFT ANGLE OF ATTACK

Reynolds number and roughness have a small effect on section zero-lift angle of attack. Reference 1 shows that variations due to these causes are usually restricted to less than 1°.

Up to the critical Mach number the effect of compressibility on the zero-lift angle of attack is negligible. Above the critical Mach number, however, compressibility effects can cause large changes in this parameter. Reference 2 presents Mach number effects on some cambered sections.

For supersonic Mach numbers it is advisable to use the method of characteristics or the generalized shock-expansion method (reference 3). The charts and tables of this Section, however, are restricted to low speeds.

HANDBOOK METHOD

Experimental data from reference 4 on the zero-lift angle of attack for NACA four- and five-digit and 6-series airfoils are presented in tables 4.1.1-A and 4.1.1-B, respectively. Data on many additional airfoils may be located in the literature with the help of table 4.1.1-C.

For airfoil series not included in this summary, the theoretical characteristics tabulated in table 4.1.1-D may be used in conjunction with the aforementioned experimental data to derive the zero-lift angle of attack according to the following method. The zero-lift angle of attack is given by the equation (assuming a lift-curve slope of 2π)

$$\alpha_o = k\left(\alpha_i - \frac{57.3}{2\pi} c_{\ell_i}\right) \qquad \text{4.1.1.1-a}$$

$$= k\left(\alpha_i - 9.12\, c_{\ell_i}\right)$$

where c_{ℓ_i} and α_i are the design lift coefficient and angle of attack for the design lift coefficient, respectively. The factor K is empirical (reference 4) and depends upon the airfoil series. For NACA airfoil sections the values are:

K = 0.93 NACA Four-Digit Series
1.08 NACA Five-Digit Series
0.74 NACA 6-Series

Theoretical section design lift coefficients and corresponding angles of attack for NACA four- and five-digit and 6-series airfoils are given in table 4.1.1-D. For airfoils other than those included in table 4.1.1-D, the tabulated values of α_i and c_{ℓ_i} may be linearly scaled, as indicated in the sample problems below and in table 4.1.1-D. The zero-lift angle of attack so obtained may be adjusted by judicious use and comparison with the experimental data of related airfoils. Wherever possible, however, experimental data should be used. The accuracy of this method as compared to experimental data is shown in table 4.1.1.1-A.

SAMPLE PROBLEM

Example 1: Find the theoretical α_o for the NACA 2415 section. The calculation of the theoretical α_o for this section should be based on the NACA 64 mean line, for which

$\alpha_i = 0.74°$ and $c_{l_i} = .76$ (Table 4.1.1-D)

$\alpha_i = (.74)\ 2/6$

$= 0.25°$

$c_{\ell_i} = (.76)\ 2/6$

$= 0.25$

From equation 4.1.1.1-a

$$\alpha_o = .93\left(.25 - \frac{57.3 \times .25}{2\pi}\right)$$

$= -1.91°$

This result compares to $\alpha_o = -2.0°$ experimentally.

Example 2: Find the theoretical α_o for the NACA 65_2 - 415, a = 0.5 airfoil. ($c_{l_i} = .4$)

The NACA a = 0.5 mean line serves as a base in this case, for which the tabulated data of table 4.1.1-D indicate that $\alpha_i = 3.04°$ when $c_{l_i} = 1.0$. The desired value of α_i for the given airfoil is then

$$\alpha_i = 3.04 \times \frac{.4}{1.0}$$

$= 1.22°$

Substitution into equation 4.1.1.1-a yields

$$\alpha_o = .74\left(1.22 - \frac{57.3 \times .4}{2\pi}\right)$$

$= -1.80°$

TABLE 4.1.1.1 A

SUBSONIC ZERO-LIFT ANGLE OF ATTACK

4.1.1.2 SECTION LIFT-CURVE SLOPE

The theoretical incompressible lift-curve slope (based on the Kutta-Joukowski hypothesis of finite velocity at the trailing edge) may be approximated by the equation (for angles of attack below α^* as given in Section 4.1.1).

$$c_{\ell_\alpha} = 6.28 + 4.7\ t/c \left[1 + .00375\ \phi_{TE}\right] \text{ (per rad)}$$

where ϕ_{TE} is the total trailing-edge angle in degrees. However, boundary-layer effects cause the actual lift-curve slopes to fall considerably below the theoretical values.

On thin wings the loss in lift-curve slope due to Reynolds-number effects is approximately 15 percent at $R_\ell = 10^6$. For thicker wings the losses are further aggravated by the adverse pressure gradient over the rear section due to thickness distribution. To a certain extent this can be correlated with trailing-edge angle. Very thin wings with leading-edge bubble-type separation also suffer additional lift-curve-slope losses. Reference 1 discusses viscous effects on the aerodynamic characteristics of wing sections.

The effects of leading-edge roughness on lift-curve slope can be very severe in some cases. Losses as large as 30 percent, due to the effects of the standard NACA leading-edge roughness, are shown in reference 7.

Up to the critical Mach number of the airfoil section, lift-curve slope follows the Prandtl-Glauert compressibility rule. Beyond the critical Mach number, thick conventional sections suffer large lift-slope changes due to local shock formation on first the upper and then the lower airfoil surfaces. References 2, 3, and 4 show these effects for a series of thick airfoils. An example of Mach-number effects on the lift-curve slope of a thin airfoil is contained in reference 5. Certain airfoils, notably the NACA 8-series (reference 6), are specifically designed to avoid these transonic effects.

Two methods are presented in this section for estimating the airfoil section lift-curve slope at speeds up to the critical Mach number. One uses the large body of available experimental section data, while the other is based on the semiempirical method of reference 8.

No specific methods are presented in the transonic and supersonic speed regimes. Transonic airfoil section characteristics are highly variable with airfoil section, and it is suggested that reference be made to experimental data on the particular airfoil in question. At supersonic speeds theoretical pressure distribution about an arbitrary section can be calculated by generalized shock-expansion theory, second-order theory, or the method of characteristics (see reference 3 of Section 4.1.1.1).

A. SUBSONIC

DATCOM METHODS

1. Method 1

Experimental lift-curve-slope data from reference 7 are presented in table 4.1.1-A for the NACA four- and five-digit airfoils and in table 4.1.1-B for the NACA 6-series airfoils. The effect of the NACA standard roughness on these data is indicated in figure 4.1.1.2-7. The NACA standard roughness is obtained by the use of 0.011-inch carborundum grains applied over the first 8 percent of the 24-inch-chord test models. Experimental lift-curve slopes for many other airfoils may be found in the literature with the aid of table 4.1.1-C.

Low-speed values of c_{ℓ_α} obtained from Section 4.1.1 may be corrected for compressibility effects up to the critical Mach number by application of the Prandtl-Glauert compressibility correction; i.e., $\left(c_{\ell_\alpha}\right)_M = c_{\ell_\alpha}/\beta$.

2. Method 2

This method is basically the semiempirical method of reference 8. The method accounts for the development of the boundary layer for airfoils with transition fixed at the leading edge and with maximum thickness less than approximately 20 percent. The airfoil section lift-curve slope at Mach numbers up to the critical Mach number is given by

$$c\ell_\alpha = \frac{1.05}{\beta}\left[\frac{c\ell_\alpha}{\left(c\ell_\alpha\right)_{\text{theory}}}\right]\left(c\ell_\alpha\right)_{\text{theory}} \qquad 4.1.1.2\text{-a}$$

where

$\left[\frac{\left(c\ell_\alpha\right)}{\left(c\ell_\alpha\right)_{\text{theory}}}\right]$ is an empirical correction factor obtained from figure 4.1.1.2-8a. This factor accounts for the development of the boundary layer towards the airfoil trailing edge. It is related to the Reynolds number with transition fixed at the airfoil leading edge, and the trailing-edge angle defined as the angle between straight lines passing through points at 90 and 99 percent of the chord on the upper and lower airfoil surfaces.

$\left(c\ell_\alpha\right)_{\text{theory}}$ is the theoretical airfoil section lift-curve slope obtained from figure 4.1.1.2-8b. The values of $\left(c\ell_\alpha\right)_{\text{theory}}$ have been determined using the Kutta-Joukowski hypothesis. Since $\left(c\ell_\alpha\right)_{\text{theory}}$ is relatively insensitive to the exact value of the trailing-edge angle, a value of $\phi_{TE} = 20^o$, representing the upper limit of the method, has been chosen as a constant in evaluating this parameter. Consequently, $\left(c\ell_\alpha\right)_{\text{theory}}$ is presented as a function only of airfoil thickness ratio.

β is the Prandtl-Glauert compressibility correction factor $\sqrt{1 - M^2}$.

The constant 1.05 of equation 4.1.1.2-a is an empirical correlation factor based on a large body of test data.

The method is limited to attached flow conditions and must therefore be applied with caution to airfoils with maximum thickness exceeding approximately 0.20c, airfoils with trailing-edge angles greater than approximately 20^o, and airfoils at high angles of attack.

Although the position of transition is important in determining the boundary-layer thickness at the trailing edge, no attempt has been made to estimate the effect of variation of transition position. The available experimental data do not clearly define the behavior of the transition-position movement; consequently, development of general design charts to predict the variation in section lift-curve slope with transition-position movement does not appear feasible. The transition will occur at or near the leading edge on both the upper and lower surfaces of the airfoil for most full-scale practical cases.

A comparison of test data with $c\ell_\alpha$ calculated by this method is presented as table 4.1.1.2-A.

Sample Problem

Method 2

Given: Airfoil tested in reference 9.

NACA 0006 airfoil $\quad M = 0.15; \beta = 0.99 \quad R_\ell = 4.5 \times 10^6 \quad t/c = 0.06$

$$\frac{Y_{90}}{2} = 0.720 \qquad \frac{Y_{99}}{2} = 0.130 \qquad \text{(Y in percent chord)}$$

Compute:

$$\tan\frac{1}{2}\phi'_{TE} = \frac{\frac{Y_{90}}{2} - \frac{Y_{99}}{2}}{9} = 0.066$$

$$\frac{c\ell_\alpha}{(c\ell_\alpha)_{theory}} = 0.880 \text{ (figure 4.1.1.2-8a)}$$

$$(c\ell_\alpha)_{theory} = 6.58 \text{ per rad (figure 4.1.1.2-8b)}$$

Solution:

$$c\ell_\alpha = \frac{1.05}{\beta}\left[\frac{c\ell_\alpha}{(c\ell_\alpha)_{theory}}\right](c\ell_\alpha)_{theory} \quad \text{(equation 4.1.1.2-a)}$$

$$= \frac{1.05}{0.99}\ (0.880)\ (6.58)$$

$$= 6.14 \text{ per rad}$$

$$= 0.107 \text{ per deg}$$

This compares with a test value of 0.103 per degree obtained from reference 9.

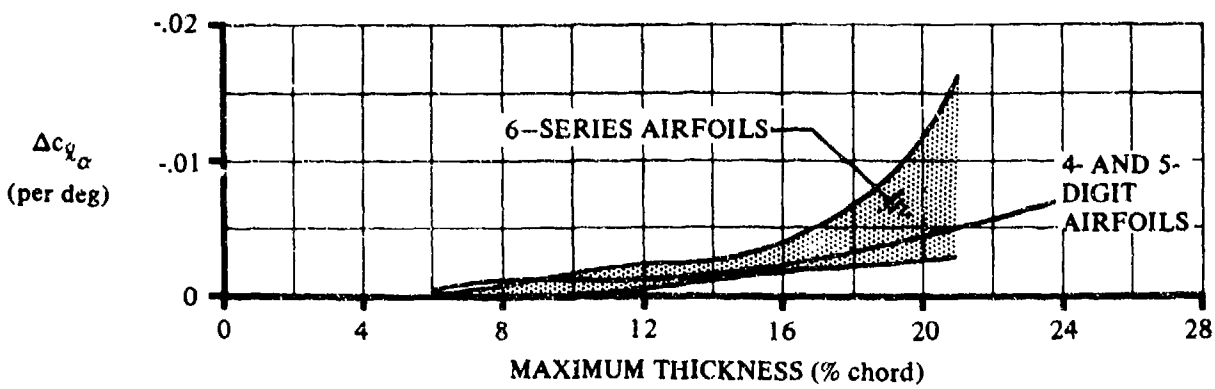

FIGURE 4.1.1.2-7 EFFECT OF NACA ROUGHNESS ON SECTION LIFT-CURVE SLOPE

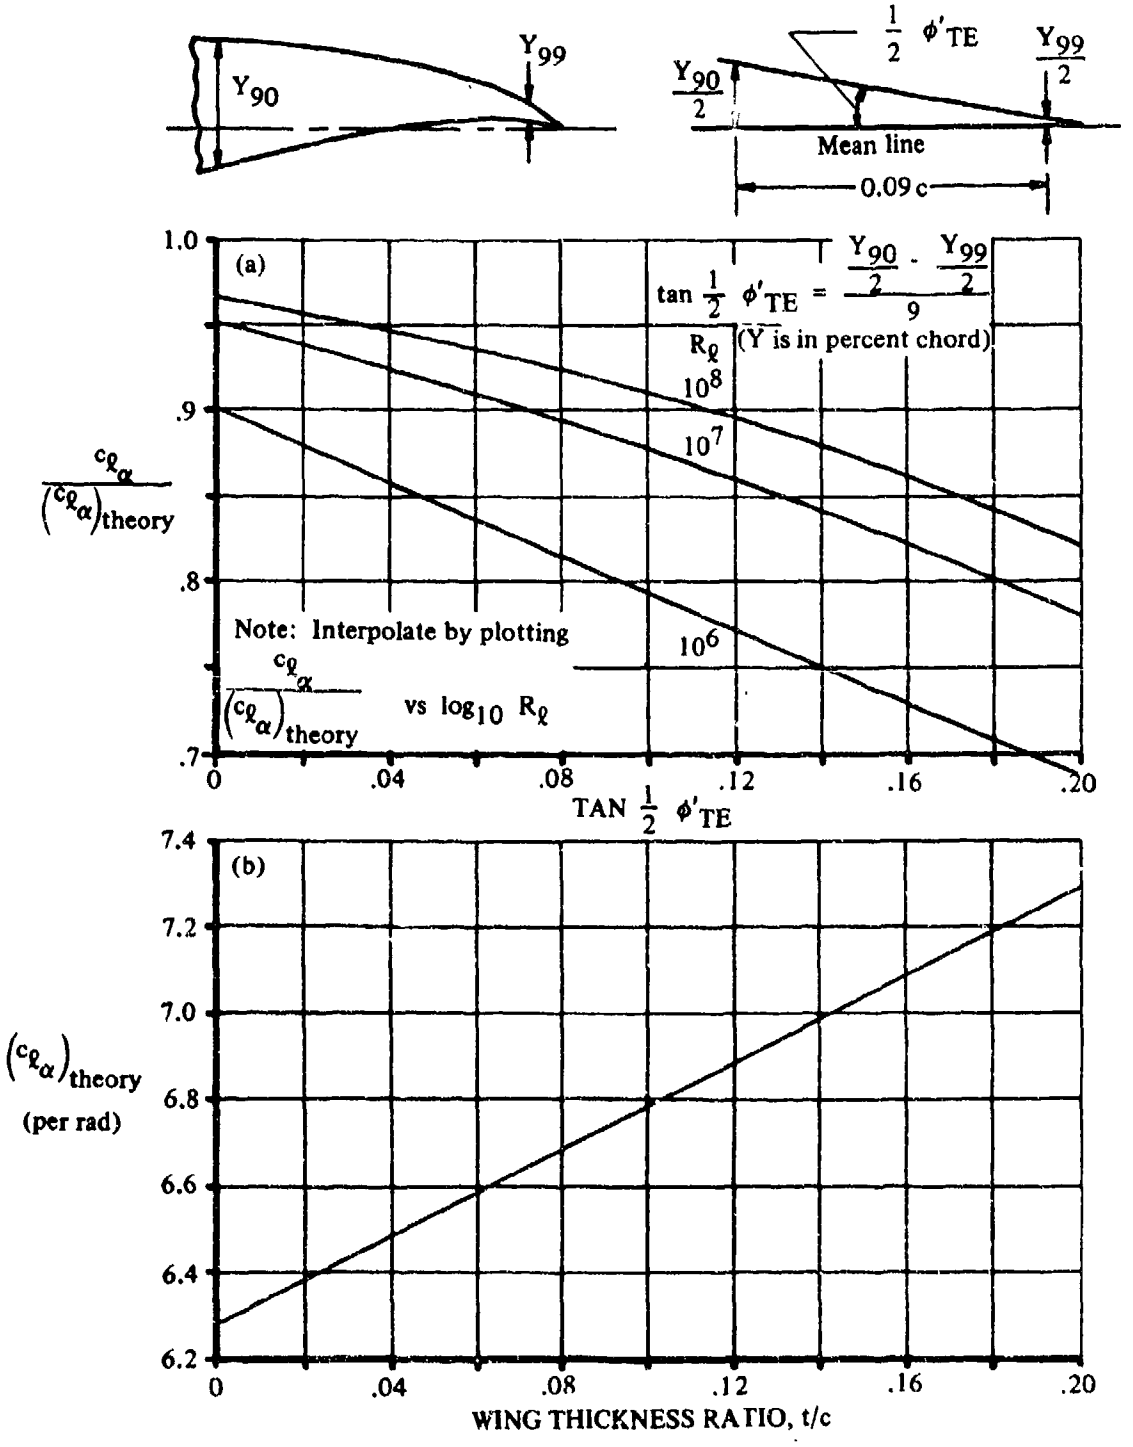

FIGURE 4.1.1.2-8 TWO-DIMENSIONAL LIFT-CURVE SLOPE METHOD 2

4.1.1.3 SECTION LIFT VARIATION WITH ANGLE OF ATTACK NEAR MAXIMUM LIFT

Flow-separation patterns, which determine the stall characteristics of airfoil sections, are due to the effects of viscosity. These flow separation patterns can be classified into three types:

1. Separation near the trailing edge.
2. Separation of the short-bubble type near the leading edge.
3. Separation of the long-bubble type near the leading edge.

A complete discussion of these types of flow separation, as they affect airfoil stall characteristics, is contained in reference 1. They are also discussed in Section 4.1.1.4 with respect to their effect on section maximum lift. Some of the more pertinent factors affecting these stall types are discussed below.

Trailing-Edge Stall

Trailing-edge stall occurs on wings of thickness-to-chord ratios of approximately 12 percent and greater. It is characterized by a gradual separation starting at the section trailing edge and progressing forward with increasing angle of attack. When the separation has moved forward to about the section midchord, maximum lift is reached. The stall for these sections is mild, with a gradual rounding of the lift and moment curves near $c_{l_{max}}$.

Leading-Edge Stall

As the thickness ratio of airfoils decreases, the nose shape becomes progressively sharper. At some point the increasingly severe adverse pressure gradients behind the nose pressure peak cause the lift of the airfoil to be limited by separation starting at the airfoil nose.

Local leading-edge separation on the airfoil upper surface may occur at angles of attack well below those for maximum lift. At these lower angles, the separated laminar boundary layer changes to turbulent and reattaches to the airfoil, leaving a bubble of trapped low-energy air between the separated boundary layer and the airfoil surface. The mechanism of the reattachment is discussed in references 2 and 3. Transition of the boundary layer must precede reattachment, and for this reason the relative stability of the boundary layer at separation is very important. If the boundary-layer Reynolds number based on the displacement thickness is greater than about 450, then transition and reattachment take place in a very short distance, giving rise to a "short bubble". If, on the other hand, the boundary-layer Reynolds number is less than 450, transition and reattachment are considerably delayed, with a resulting "long bubble". The different characteristics of these two bubbles and their effects on stall are discussed below.

. . . . Short-Bubble Leading-Edge Stall

The short bubble is characteristically one percent of the airfoil chord in length and decreases in size with increasing angle of attack. Because of its small size, the bubble has little effect on the section pressure distribution until at some angle of attack the flow abruptly ceases to reattach, thereby separating the flow over the entire upper surface of the airfoil. For this airfoil the lift and pitching-moment curves are quite linear right up to stall. The stall itself is violent, with large changes in lift and pitching moment.

. . . . Long-Bubble Leading-Edge Stall

The long bubble, like the short bubble, consists of a laminar separation followed by a turbulent reattachment. However, as the angle of attack increases, the size of the long bubble also increases until, at maximum lift, the bubble covers the entire upper surface of the airfoil.

For the long-bubble type of separation, the maximum lift achieved is, in general, lower than that for either the short-bubble type or the trailing-edge type. The stall for the long bubble is mild, with gradual rounding of the lift and moment curves.

Reynolds Number Effects

Since the type of bubble formed depends on the Reynolds number of the boundary layer at the point of separation, it is apparent that changes in free-stream Reynolds number can cause the stall of an airfoil to change from one type to another. If the Reynolds number is high enough, boundary-layer transition may take place before the point where laminar separation would occur, and no bubble will be formed at all. The tables and charts pertaining to this section are based primarily on a Reynolds number of 9×10^6. For other Reynolds numbers, reference 4 may be used, which contains a summary of the types of stall to be expected as a function of Reynolds number.

HANDBOOK METHOD

The shape of the section lift curve just below the stall angle of attack can be approximated from a knowledge of the angle of attack at which the lift curve begins to deviate from the linear slope, the maximum lift, angle of attack for maximum lift, and the lift-curve slope. The lift curve just before the stall can then be constructed with acceptable accuracy, as illustrated schematically in Section 4.1.1.

The parameters $c_{\ell_{max}}$, $\alpha_{c_{\ell_{max}}}$, and α_0 are discussed in Sections 4.1.1.4 and 4.1.1.1. The angle of attack α^* at which the lift curve deviates from the linear is tabulated for the NACA four-and five-digit and 6-series airfoils in tables 4.1.1-A and 4.1.1-B, respectively. The data, from reference 5, are for smooth surfaces, 9×10^6 Reynolds number, and low speeds.

4.1.1.4 SECTION MAXIMUM LIFT

Subsonic section maximum lift is sensitive to many parameters, including airfoil thickness, location of maximum thickness, camber, position of maximum camber, Mach number, Reynolds number, free-stream turbulence, and airfoil surface condition (roughness). These parameters influence section maximum lift by determining the type of flow separation that limits the lift. Broadly speaking, the separation patterns may be classified into three types:

1. Trailing-edge separation.
2. Leading-edge separation of the short-bubble type.
3. Leading-edge separation of the long-bubble type.

The distinctive features of each of these types of separation are discussed in section 4.1.1.3.

For airfoils that stall as a result of flow separation from the leading edge (thin airfoils), the section maximum lift may be correlated with airfoil-leading-edge geometry. The leading-edge parameter that best correlates the section maximum lift is the Δy-parameter, the difference between the upper-surface ordinates at the 6-percent-chord and 0.15-percent-chord stations, respectively. This parameter is presented as a function of airfoil thickness for several standard airfoils in Section 2.2.1.

For thicker symmetrical airfoils, i.e., those that stall as a result of separation from the trailing edge, a relatively local leading-edge parameter is no longer sufficient. The maximum lift of these sections is correlated by using the position of maximum thickness in addition to the Δy-parameter.

Reference 1 indicates that for thin airfoils there is a maximum lift increment due to camber when the pressure distribution near the nose is identical to that of the corresponding uncambered airfoil. The procedure used in the Handbook is to add an increment of lift, accounting for the effect of camber, to the symmetrical-airfoil maximum lift. Empirically, the increment is a function of maximum-thickness position as well as position and magnitude of maximum camber.

Reynolds number and free-stream turbulence are analogous in their effects on section maximum lift. For thin airfoils an increase in Reynolds number or turbulence causes boundary-layer transition earlier, changing a long-bubble to a short-bubble separation. This increases lift. Roughness, if it causes transition early enough, has the same effect. For thicker airfoils roughness merely decreases the energy of the boundary layer, thus lowering maximum lift.

Mach number effects are very severe on thick airfoils. Maximum lift coefficient begins to drop, starting at $M \approx 0.2$, as illustrated typically in figure 4.1.1.4-8b.

For supersonic speeds, maximum lift can be calculated by the method of reference 2, which makes the assumptions that the upper-surface limit pressure is 70 percent of vacuum and the lower-surface pressure is a function of the total pressure behind a normal shock wave at the free-stream Mach number and the projected area of the lower surface perpendicular to the free-stream direction. Section maximum-lift values obtained by this procedure appear to be slightly low.

HANDBOOK METHOD

In this Section two-dimensional-airfoil maximum-lift information is presented in two forms: tabulated data for specific NACA airfoils and generalized design charts from which the maximum lift of nonstandard airfoils may be approximated. Actual test data should be used whenever possible, however.

Section data for maximum lift and angle of attack for maximum lift for the NACA four- and five-digit airfoils are presented in table 4.1.1-A for smooth-leading-edge conditions, a Reynolds number of 9×10^6, and low speeds. Corresponding information for the NACA 6-series airfoils is presented in table 4.1.1-B. Additional airfoils may be located in the literature with the aid of table 4.1.1-C.

The generalized design charts of this Section are empirically derived from experimental data of references 3, 4, 5, and 6. The section maximum lift coefficient is determined by the equation

$$c_{\ell_{max}} = (c_{\ell_{max}})_{base} + \Delta_1 c_{\ell_{max}} + \Delta_2 c_{\ell_{max}} + \Delta_3 c_{\ell_{max}} + \Delta_4 c_{\ell_{max}} + \Delta_5 c_{\ell_{max}} \qquad 4.1.1.4\text{-a}$$

where the various contributions are obtained as follows:

1. $(c_{\ell_{max}})_{base}$ is obtained from figure 4.1.1.4-5 as a function of Δy and position of maximum thickness. The Δy-parameter for a cambered airfoil is the same as that of the corresponding uncambered airfoil, that is, the uncambered airfoil having the same thickness distribution. This reference value is for uncambered airfoils with smooth leading edges, at 9×10^6 Reynolds number and low speed.

2. $\Delta_1 c_{\ell_{max}}$ accounts for the effect of camber for airfoils having the maximum thickness at 30-percent chord. Figure 4.1.1.4-6 gives $\Delta_1 c_{\ell_{max}}$ as a function of percent camber and maximum-camber location. The percent camber and position of maximum camber for standard NACA airfoils are discussed in Section 2.2.1.

3. $\Delta_2 c_{\ell_{max}}$ amounts to an increment by which $\Delta_1 c_{\ell_{max}}$, the "camber" term for airfoils having their maximum thickness at 30-percent chord, must be modified for airfoils having their maximum thickness at some other position. This increment is obtained from figure 4.1.1.4-7a. (If the maximum thickness is at 30-percent chord, $\Delta_2 c_{\ell_{max}}$ is zero).

4. $\Delta_3 c_{\ell_{max}}$, presented in figure 4.1.1.4-7b, gives the lift increment due to Reynolds number for Reynolds numbers other than 9×10^6.

5. $\Delta_4 c_{\ell_{max}}$, shown in figure 4.1.1.4-8a, gives the lift increment due to roughness. The roughness in this case is the standard NACA roughness and is represented by 0.011-inch grit applied over the first 8-percent chord. This curve is given only as an indication of roughness effects. Actual airplane roughnesses vary considerably and their effects may be quite different from those shown in figure 4.1.1.4-8a.

6. $\Delta_5 c_{\ell_{max}}$ is a correction for Mach numbers greater than approximately 0.2. No generalized charts are presented for Mach number effects. The lift increment due to Mach number should be obtained from test data of similar airfoils when available. Figure 4.1.1.4-8b shows representative effects on particular airfoils.

Table 4.1.1.4-A compares experimental data with results obtained by the use of this method.

SAMPLE PROBLEM

Given:

66_2-415 Airfoil section

$R = 6 \times 10^6$

$M = .10$

Airfoil surface in smooth condition

Compute:

t/c = 15-percent chord*

Position of maximum thickness: 45-percent chord*

Position of maximum camber: 50-percent chord*

Amount of camber: 2.2-percent chord*

$\Delta y = 2.75$ (from Section 2.2.1)

$(c_{\ell_{max}})_{base} = 1.34$ (from figure 4.1.1.4-5)

$\Delta_1 c_{\ell_{max}} = .16$ (from figure 4.1.1.4-6)

$\Delta_2 c_{\ell_{max}} = .08$ (from figure 4.1.1.4-7a)

$\Delta_3 c_{\ell_{max}} = -.02$ (from figure 4.1.1.4-7b)

$\Delta_4 c_{\ell_{max}} = 0$

$\Delta_5 c_{\ell_{max}} = 0$

*See Section 2.2.1 for airfoil description

Solution:

$$c_{\ell_{max}} = (c_{\ell_{max}})_{base} + \Delta_1 c_{\ell_{max}} + \Delta_2 c_{\ell_{max}} + \Delta_3 c_{\ell_{max}} + \Delta_4 c_{\ell_{max}} + \Delta_5 c_{\ell_{max}}$$

$$= 1.56$$

$c_{\ell_{max}} = 1.60$ from test data of reference 4.

4.1.2 SECTION PITCHING MOMENT

4.1.2.1 SECTION ZERO-LIFT PITCHING MOMENT

The zero-lift pitching-moment coefficient is included for various NACA four- and five-digit and NACA 6-series airfoil sections in tables 4.1.1-A and 4.1.1-B. These data should be used wherever possible in preference to theoretical data in stability and control calculations.

These tables are applicable to Mach numbers below the critical. Above the critical Mach number, appreciable changes in zero-lift pitching moment may be present because of compressibility effects.

Additional section data may be located in the literature with the aid of table 4.1.1-C.

The theoretical pitching-moment coefficients of the various airfoil mean lines at the design lift coefficients are proportional to the section design lift coefficient or mean-line ordinate (camber) and may be scaled up or down as shown in the sample problems below or in table 4.1.1-D. Since the theoretical thin-airfoil aerodynamic center is at the quarter-chord point, the theoretical zero-lift pitching moment is identical to the theoretical pitching moment about the quarter-chord point at the design lift coefficient, shown in table 4.1.1-D.

Sample Problems

Example 1: Find the theoretical c_{m_0} about the quarter-chord point for the 2415 airfoil. Using the 64 mean line as a base, for which $c_{m_0} = -0.157$(table 4.1.1-D), the required pitching-moment coefficient is

$$c_{m_0} = -.157 \times 2/6$$
$$= -.052$$

The experimental value for this section is -.049 (table 4.1.1-A).

Example 2: Find the c_{m_0} about the quarter-chord point for the NACA 65_3-215, $a = 0.5$ airfoil. The design lift coefficient for this airfoil is 0.2. Using the 6-series mean line for $a = 0.5$, for which $c_{m_0} = -.139$ (table 4.1.1-D), gives the desired pitching-moment coefficient:

$$c_{m_0} = -.139 \times .2$$
$$= -.028$$

4.1.2.2 SECTION PITCHING-MOMENT VARIATION WITH LIFT

A. SUBSONIC

The aerodynamic center of thin airfoil sections is theoretically located at the quarter-chord point. Experimentally, the aerodynamic-center location is a function of section thickness ratio and trailing-edge angle. Experimental data should always be used in preference to the theory.

The summary of experimental aerodynamic characteristics of various NACA four- and five-digit and 6-series airfoil sections given in tables 4.1.1-A and 4.1.1-B includes aerodynamic-center location.

Figure 4.1.2.2-3 presents the generalized aerodynamic center for the useful range of airfoil thickness ratios and trailing-edge angles. Trailing-edge angles, as defined on figure 4.1.2.2-3 are given for standard NACA airfoils in Section 2.2.1. A comparison of experimental data with results based on these charts is shown in table 4.1.2.2-A.

B. SUPERSONIC

Section pitching-moment variation with lift at supersonic speeds is primarily a function of section thickness, thickness distribution, and camber. For conditions where there is no flow separation, shock-expansion theory gives results that are in good agreement with experimental data.

At the higher angles of attack, especially for the thicker sections, flow separation takes place on the upper rear portion of the airfoil. Under these circumstances the experimental center of pressure is farther forward than that predicted by theory.

At very high angles of attack, the shock detaches from the section leading edge. The center of pressure then tends toward the 50-percent-chord point as the angle of attack increases toward 90°

Figure 4.1.2.2-4 gives the position of the center of pressure for three airfoil sections as a function of Mach number, angle of attack, and thickness ratio. These results are calculated from shock-expansion theory (reference 1) and are strictly applicable only when the flow is everywhere attached.

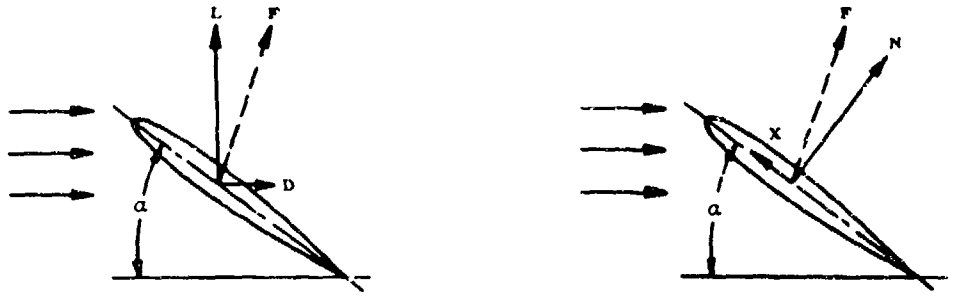
4.1.3 WING LIFT

In the following group of Sections, (4.1.3.1 through 4.1.3.4), methods are presented for calculating the lift and normal force on wings at any angle of attack and any speed. An accurate determination of wing lift characteristics is important, since many other calculations are based on the wing-alone properties, e.g., all wing-body lift estimates and wing and wing-body rolling-moment calculations.

For this reason the approximations that are made in calculating wing lift in certain of the following Sections must be clearly understood in terms of their effect on the accuracy of the resulting numerical values.

The aerodynamic forces acting on a wing may be represented by a single force vector. This vector is conventionally resolved into two orthogonal components. The directions of the components are defined by the axis system selected. The two axis systems used most often are illustrated in the sketch below.



LIFT AXIS SYSTEM NORMAL-FORCE AXIS SYSTEM

In the lift axis system, the force vector F is resolved into components perpendicular and parallel to the free stream. These components are called lift and drag, respectively. In the normal-force axis system, the force vector is resolved into components perpendicular to and parallel to the wing chord, called the normal force and the chord force, respectively.

The equations relating the lift, drag, normal-force, and chord-force coefficients are

$$C_N = C_L \cos \alpha + C_D \sin \alpha \qquad \text{4.1.3-a}$$

$$C_X = - C_D \cos \alpha + C_L \sin \alpha \qquad \text{4.1.3-b}$$

$$C_L = C_N \cos \alpha + C_X \sin \alpha \qquad \text{4.1.3-c}$$

$$C_D = C_N \sin \alpha - C_X \cos \alpha \qquad \text{4.1.3-d}$$

If the resultant force vector is nearly normal to the wing surface, the chordwise force component can be neglected and

$$F \approx N \quad X \approx 0$$

$$C_L \approx C_N \cos \alpha \qquad \text{4.1.3-e}$$

$$C_D \approx C_N \sin \alpha \qquad \text{4.1.3-f}$$

The resultant force vector is nearly normal to the wing surface for all low-aspect-ratio wings and for high-aspect-ratio wings at angles of attack beyond the stall at subsonic speeds. It is also nearly normal to the wing surface for all wings at supersonic speeds. However, for high-aspect-ratio wings at angles of attack below the stall, the resultant force vector is more nearly perpendicular to the free-stream direction than normal to the wing surface.

For purposes of continuity through the complete speed and angle-of-attack envelope it is convenient to introduce a pseudonormal force C_N', defined by the equation

$$C_{N'} = \frac{C_L}{\cos \alpha} \qquad \text{4.1.3-g}$$

As indicated by the discussion above, this $C_{N'}$ is essentially the true normal force for all situations except that of high-aspect-ratio wings at angles of attack below the stall.

In the following Sections $C_{N'}$ is used for C_N throughout. Sample problems in Section 4.1.3.3 show comparisons between experimental C_N values and calculated $C_{N'}$ values, and between experimental and calculated C_L values for several configurations.

4.1.3.1 WING ZERO-LIFT ANGLE OF ATTACK

The method presented in this section is restricted to subsonic speeds. In the transonic and supersonic speed regimes it is suggested that reference be made to experimental data.

A. SUBSONIC

The effect of planform geometry on the zero-lift angle of attack of untwisted, constant-section wings is relatively small. Therefore, the method applied to such planforms is based on airfoil section properties.

For untwisted, constant-section wings the zero-lift angle of attack, taken from reference 1, is

$$(\alpha_0)_{\theta=0} = \alpha_i - \frac{c_{\ell_i}}{c_{\ell_\alpha}} \quad \text{(degrees)} \qquad 4.1.3.1\text{-a}$$

where c_{ℓ_i}, α_i, and c_{ℓ_α} are the section design lift coefficient, angle of attack for design lift coefficient, and section lift-curve slope, respectively. These data may be obtained from Section 4.1.1.

Equation 4.1.3.1-a is applicable to swept wings if the airfoils are defined parallel to the free stream.

If definition of the airfoil section parallel to the free stream is not available for a particular swept wing, then α_0 may be approximated by

$$(\alpha_0)_{\substack{\theta=0 \\ \Lambda}} = \tan^{-1}\left[\tan (\alpha_0)_{\substack{\theta=0 \\ \Lambda=0}} \frac{1}{\cos \Lambda}\right] \quad \text{(degrees)} \qquad 4.1.3.1\text{-b}$$

where

Λ is the sweepback of some constant-percent chord line.

$(\alpha_0)_{\substack{\theta=0 \\ \Lambda=0}}$ is the zero-lift angle of attack of an untwisted, constant-section wing of zero-degree sweepback obtained by using equation 4.1.3.1-a. Values of c_{ℓ_i}, α_i, and c_{ℓ_α} used in equation 4.1.3.1-a are based on the airfoil section in a plane normal to the particular constant-percent chord line.

For wings with constant airfoil sections and linear twist, lifting-line theory may be used as in reference 2 to obtain α_0 as a function of planform geometry. This method uses the equation

$$\alpha_0 = (\alpha_0)_{\theta=0} + \left(\frac{\Delta\alpha_0}{\theta}\right)\theta \quad \text{(degrees)} \qquad 4.1.3.1\text{-c}$$

where

$(\alpha_0)_{\theta=0}$ is the zero-lift angle of attack of the untwisted, constant-section wing, given by equation 4.1.3.1-a.

$\frac{\Delta\alpha_0}{\theta}$ is the change in wing zero-lift angle of attack due to a unit change in linear wing twist. This parameter is obtained from figure 4.1.3.1-4.

θ is the twist of the wing tip with respect to the root section, in degrees (negative for washout). A linear spanwise twist distribution is assumed (all constant-percent points of the local chords lie in straight lines along the span).

Test data have indicated that if the airfoil is cambered the zero-lift angle of attack varies with Mach number, particularly above the critical Mach number. A Mach number correction to be applied to cambered airfoils is presented as figure 4.1.3.1-5. This chart gives the ratio of the zero-lift angle of attack at any subsonic Mach number to the corresponding value at M = 0.3. This chart is based on the data of references 3, 4, and 5 and is to be considered as a first-order approximation only.

Unfortunately, there are not enough data to substantiate the theoretical results as applied to either untwisted or twisted wings. Consequently, experimental data should be used whenever possible.

Sample Problem

Given: An untwisted, constant-section wing.

$A = 6.0 \qquad \Lambda_{c/4} = 6.34^o \qquad \lambda = 0.50 \qquad \theta = 0$

NACA 23012 airfoil (streamwise) $\qquad \frac{Y_{90}}{2} = 1.455 \qquad \frac{Y_{99}}{2} = 0.265$

Low speed; $\beta = 1.0 \qquad R_\ell = 1 \times 10^6$ (based on MAC)

Compute:

$\left.\begin{array}{l} \alpha_i = 1.65^o \\ c_{\ell_i} = 0.30 \end{array}\right\}$ (table 4.1.1-D)

Determine c_{ℓ_α} (Section 4.1.1.2)

$$\tan \frac{1}{2}\phi'_{TE} = \frac{\frac{Y_{90}}{2} - \frac{Y_{99}}{2}}{9} = \frac{1.455 - 0.265}{9} = 0.132$$

$$\frac{c_{\ell_\alpha}}{(c_{\ell_\alpha})_{theory}} = 0.760 \quad \text{(figure 4.1.1.2-8a)}$$

$$(c_{\ell_\alpha})_{theory} = 6.89 \text{ per rad} \quad \text{(figure 4.1.1.2-8b)}$$

$$c_{\ell_\alpha} = \frac{1.05}{\beta}\left[\frac{c_{\ell_\alpha}}{(c_{\ell_\alpha})_{theory}}\right](c_{\ell_\alpha})_{theory} \quad \text{(equation 4.1.1.2-a)}$$

$$= \frac{1.05}{1.0}\ [0.760]\ (6.89) = 5.50 \text{ per rad}$$

$$= 0.096 \text{ per deg}$$

Solution:

$$(\alpha_0)_{\theta=0} = \alpha_i - \frac{c_{\ell_i}}{c_{\ell_\alpha}} \quad \text{(equation 4.1.3.1-a)}$$

$$= 1.65 - \frac{0.30}{0.096}$$

$$= -1.48 \text{ deg}$$

4.1.3.2 WING LIFT-CURVE SLOPE

The lift on a wing at angle of attack results from the distributed pressures over the surface of the wing. At subsonic speeds, most of the lift on a wing is derived from a region of low pressure on the upper surface near the leading edge. The magnitude and distribution of this pressure field is such that its integrated value over the wing surface results in a force vector that is very nearly perpendicular to the free-stream direction. This is the well-known lift-force vector. The rate of change of this vector with angle of attack is the lift-curve slope $dC_L/d\alpha$, usually written as C_{L_α}.

At supersonic speeds the pressure distribution over the wing is quite different. The pressure integration results in a force vector that is more nearly perpendicular to the wing-chord plane rather than to the free-stream direction. This is called the normal force and its variation with angle of attack in coefficient form is $dC_N/d\alpha$, or C_{N_α}.

For small angles of attack, C_{L_α} is interchangeable with C_{N_α}. At higher angles of attack the distinction is important.

For finite, three-dimensional wings, the free-stream direction with reference to the wing local-airfoil sections is determined by the free-stream angle of attack decreased by the local induced angle of attack. The lift vector is tilted back by an angle equal to the local induced angle. This force vector can be resolved into two components -- one perpendicular to and one parallel to the free-stream direction.

For high-aspect-ratio wings there is a certain justification in using C_{L_α} as C_{N_α} below stall angles, since the induced angle is small. For angles of attack beyond the stall, the total-force vector is essentially normal to the wing chord. For very low-aspect-ratio wings at high angles of attack, the induced effects are large and the local-force vector is tilted back through a large angle.

A. SUBSONIC

Theories for calculating the subsonic lift on three-dimensional wings fall into two general classes, lifting-surface theories and lifting-line theories. Lifting-surface theories, such as those of References 1 and 2, give highly accurate results for both wing lift and pitching moment. Since they are rather difficult to apply, however, they are usually reserved for detailed analyses of specific wings, particularly low-aspect-ratio wings, where the induced-camber and induced-angle-of-attack effects are important.

Lifting-line theories are widely used for calculating the lift-curve slopes of high-aspect-ratio wings, where chord-loading effects are less important. Certain modified lifting-line theories (References 3 and 4) give lift-curve slopes (but not pitching moments) that are quite accurate, even for very low aspect ratios. The explanation for this unexpected accuracy is given in Reference 5.

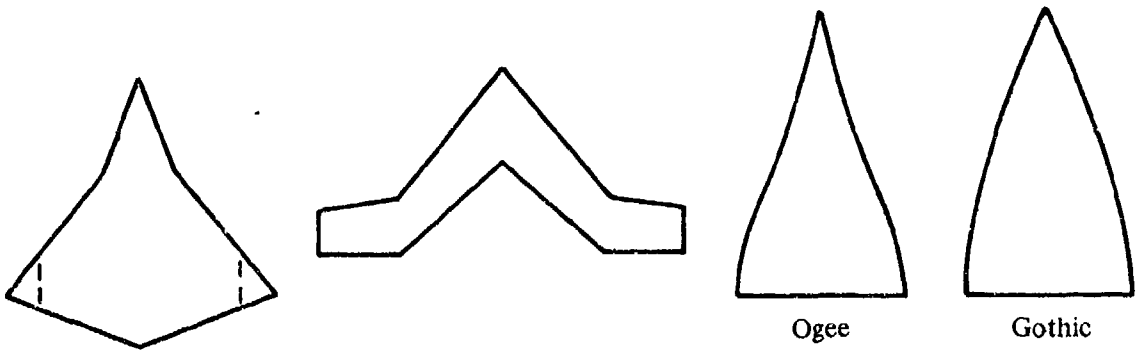
At subsonic speeds methods are presented for determining the lift-curve slope of the following two classes of wing planforms:

Straight-Tapered Wings (conventional, fixed trapezoidal wings)

Non-Straight-Tapered Wings

Double-delta wings (composite wings with A ≈ 3 or less)
Cranked wings (composite wings with A ≈ 3 or greater)
Curved (Gothic and ogee) wings

These three general categories of non-straight-tapered wings are illustrated in Sketch (a), and their wing-geometry parameters are presented in Section 2.2.2.



SKETCH (a)

Two separate methods are presented for straight-tapered wings. Method 1, taken from Reference 3, is applicable to the majority of configurations. In this method, the wing taper ratio has been eliminated as a parameter by the use of the midchord sweep angle rather than the conventional quarter-chord or leading-edge sweep angle. This permits a considerable simplification in the presentation of wing-lift-curve-slope information. Because of this simplification, the method of Reference 3 has been chosen for presentation in this section for estimating the lift-curve slope of straight-tapered wings. It gives results that agree with slender-wing theory (Reference 6) at very low aspect ratios and with two-dimensional section data at infinite aspect ratios.

Method 2, taken from Reference 7, is applicable only at M = 0.2 for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with large thickness ratios; i.e., $0.10 \leqslant t/c \leqslant 0.30$. The unique feature of this method is its consideration of the vortex-induced lift. In contrast to the conventional constant lift-curve slope, this method allows for one or two breaks in the lift-curve slope to account more accurately for the vortex-induced lift contribution.

The lift-curve slopes of non-straight-tapered wings are treated in Reference 8. The planforms investigated include double delta, cranked, and curved (Gothic and ogee). Methods for predicting the lift-curve slope near zero lift for these planforms are based on the work of Spencer in Reference 9. This work consists of an extension of the results presented for conventional wings in Reference 3 to include wings having variation in sweep along the span. Since lift curves of double-delta and curved wings are considered nonlinear throughout the lift range, the lift-curve slope near zero lift is of little significance by itself. On the other hand, experimental results show

that the lift curves for cranked wings (defined as composite wings with aspect ratios approximately three or greater) exhibit a linear range up to approximately eight degrees angle of attack. Consequently, the method of Reference 9, as modified by an empirical correlation factor, is used for the prediction of C_{L_α} for cranked wings with round-nosed airfoils.

DATCOM METHODS

Straight-Tapered Wings

Method 1

The three-dimensional lift-curve slope of conventional wings is presented in Figure 4.1.3.2-49 as a function of wing aspect ratio, midchord sweep angle, Mach number, and section (defined parallel to the free stream) lift-curve slope. The factor κ of Figure 4.1.3.2-49 is the ratio of the two-dimensional lift-curve slope (per radian) at the appropriate Mach number to $2\pi/\beta$; i.e., $(c_{\ell_\alpha})_M / (2\pi/\beta)$. Section lift-curve slope (per degree) is obtained from Section 4.1.1.2.

A sweep-conversion formula is given in Section 2.2.2, from which the midchord sweep for any straight-tapered wing may be determined.

Application of the method is illustrated in the sample problem following the non-straight-tapered-wing methods of this paragraph, and in the sample problems following the straight-tapered-wing methods for transonic speeds in Paragraph B.

Method 2

This semiempirical method is taken from Reference 7, ignoring the small wing-planform nose-radius effects. The semiempirical method was developed by using the test results of Reference 7, correlated with the theoretical predictions based on lifting-surface theory. Because of its semiempirical nature, the method should be restricted to M = 0.2 conditions for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with the following geometric characteristics:

$$0.58 \leq A \leq 2.55$$

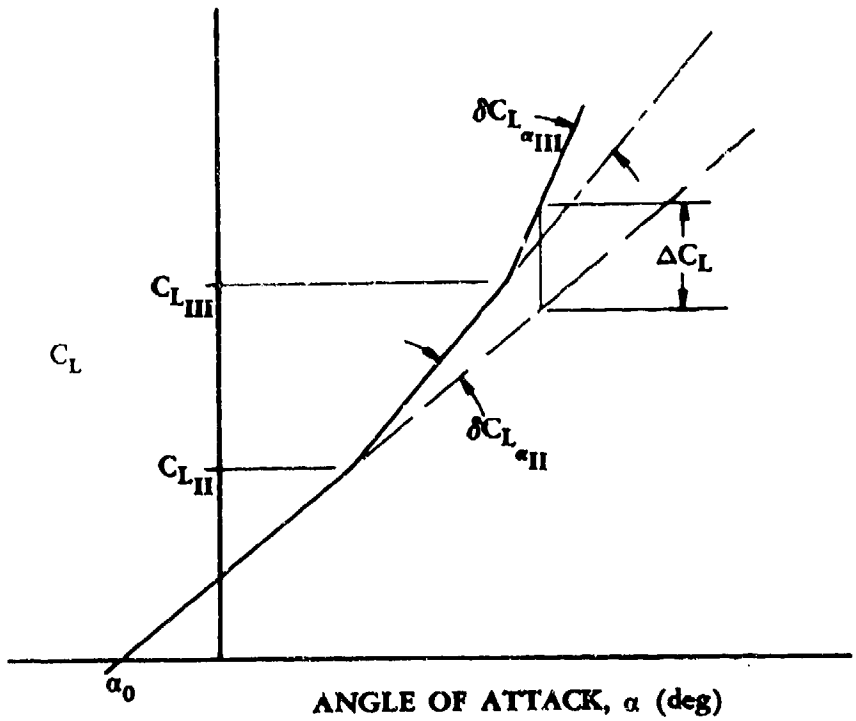
$$0 \leq \lambda \leq 0.3$$

$$63^\circ \leq \Lambda_{LE} \leq 80^\circ$$

$$0.10 \leq t/c \leq 0.30$$

$$\Lambda_{TE} = 0$$

The determination of the breaks in the lift-curve slope ($C_{L_{II}}$ and $C_{L_{III}}$ in Sketch (b)), is contingent upon the availability of section upper-surface pressure data for the particular airfoil section being considered. In the method formulation of Reference 7, the pressure data were derived by means of a computer-program solution for the potential flow equations for two-dimensional incompressible flow, by the method of conformal transformation according to Imai (Reference 10). However, test data from Reference 11 or any other source of valid experimental data will satisfy the requirement.



SKETCH (b)

For round-nosed-planform configurations, the reader is referred to Reference 7, where three different planform nose-radius models were tested. Although a procedure was developed to account for the incremental nose-radius effects, it requires a computer-program lifting-surface theory as a basis.

The lift-curve slope for a low-aspect-ratio, delta or clipped-delta wing may be approximated by the following procedure:

Step 1. Determine the low-lift-region lift-curve slope uncorrected for thickness effects by

$$\left(C_{L_\alpha}\right)_{\text{theory}} = 8 \tan^{-1} \frac{\pi A}{16 + \pi A/(1 + 2\lambda \tan \Lambda_{LE})} \qquad 4.1.3.2\text{-a}$$

where

A is the wing aspect ratio.

λ is the wing taper ratio.

Λ_{LE} is the wing leading-edge sweep.

Step 2. Determine the low-lift-region lift-curve slope, based on the wing planform area, by correcting the theoretical value in Step 1 for thickness effects.

$$\left(C_{L_\alpha}\right)_{basic} = \left(C_{L_\alpha}\right)_{theory} \left[\frac{C_{L_\alpha}}{\left(C_{L_\alpha}\right)_{theory}}\right] \qquad 4.1.3.2\text{-b}$$

where

$\left(C_{L_\alpha}\right)_{theory}$ is from Step 1 above.

$\frac{C_{L_\alpha}}{\left(C_{L_\alpha}\right)_{theory}}$ is from Figure 4.1.3.2-50a as a function of aspect ratio, taper ratio, and thickness ratio.

Step 3. Plot the maximum negative upper-surface section pressure coefficient C_{p_u} and its corresponding section lift coefficient c_ℓ on Figure 4.1.3.2-50b for three or four different section lift coefficients. These pressure data are supplied by the user and may be theoretical or taken from a source of experimental data such as Reference 11. When a sufficient number of points have been plotted, fair a smooth line through the points. Now determine where the faired line intersects the value of $\left(C_{L_\alpha}\right)_{theory}$ as determined above in Step 1. The point of intersection determines the value of $C_{L_{II}}$, read on the abscissa scale of the figure. The value for $C_{L_{II}}$ is the lift coefficient where the vortex lift component necessitates the first change in the lift-curve slope (see Sketch (b)). The point of intersection also defines the maximum negative upper-surface section pressure coefficient C_{p_u} used in the next step.

Step 4. Plot the maximum negative upper-surface section pressure coefficient C_{p_u} versus its corresponding nondimensional chordwise location x/c. (These pressure data are supplied by the user as above in Step 3.) Read the chordwise location x/c corresponding to the value of C_{p_u} determined in Step 3.

Step 5. Determine the value of $C_{L_{III}}$ from Figure 4.1.3.2-51 as a function of taper ratio, sweep, thickness ratio, and the chordwise location of C_{p_u}. The value for $C_{L_{III}}$ is the lift coefficient where the vortex lift component necessitates a second change in the lift-curve slope (see Sketch (b)).

Step 6. Determine the value of $\left(C_{L_\alpha}\right)_{limit}$ from the following:

$$\left(C_{L_\alpha}\right)_{limit} = 0.0467 \left(\sin \Lambda_c\right)^{1/4} \text{ (per deg)} \qquad 4.1.3.2\text{-c}$$

where

Λ_c is the complement of the leading-edge sweep angle Λ_{LE}; i.e., $\Lambda_c = 90^\circ - \Lambda_{LE}$.

Step 7. Determine the incremental increase in lift-curve slope $\delta C_{L_{\alpha_{II}}}$ starting at $C_{L_{II}}$ according to the following criteria:

If	Then
$\left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic} \geq 0.0067$;	$\delta C_{L_{\alpha_{II}}} = 0.0067$ per deg
$\left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic} < 0.0067$;	$\delta C_{L_{\alpha_{II}}} = \left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic}$
$\left(C_{L_\alpha}\right)_{limit} \leq \left(C_{L_\alpha}\right)_{basic}$;	$\delta C_{L_{\alpha_{II}}} = 0$

Step 8. Determine the total lift-curve slope in the region between $C_{L_{II}}$ and $C_{L_{III}}$ using

$$\left(C_{L_\alpha}\right)_{II} = \left(C_{L_\alpha}\right)_{basic} + \left(\delta C_{L_\alpha}\right)_{II} \qquad 4.1.3.2\text{-d}$$

where

$\left(C_{L_\alpha}\right)_{basic}$ is from Step 2.

$\left(\delta C_{L_\alpha}\right)_{II}$ is from Step 7.

Step 9. Determine the incremental increase in lift-curve slope $\delta C_{L_{\alpha_{III}}}$ starting at $C_{L_{III}}$ according to the following criteria:

If	Then
$\left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic} \geq 0.012$;	$\left(\delta C_{L_\alpha}\right)_{III} = 0.012$ per deg
$\left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic} < 0.012$;	$\left(\delta C_{L_\alpha}\right)_{III} = \left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic}$
$\left(C_{L_\alpha}\right)_{limit} \leq \left(C_{L_\alpha}\right)_{basic}$;	$\left(\delta C_{L_\alpha}\right)_{III} = 0$

Step 10. Determine the total lift-curve slope in the region beyond $C_{L_{III}}$ using

$$\left(C_{L_\alpha}\right)_{III} = \left(C_{L_\alpha}\right)_{basic} + \left(\delta C_{L_\alpha}\right)_{III} \qquad 4.1.3.2\text{-e}$$

where

$\left(C_{L_\alpha}\right)_{basic}$ is from Step 2.

$\left(\delta C_{L_\alpha}\right)_{III}$ is from Step 9.

The entire lift-curve slope may now be constructed as shown in Sketch (b). (Note that the wing zero-lift angle of attack α_0 is determined by using Section 4.1.3.1.)

No substantiation of this method is possible because of the lack of low-aspect-ratio test data having wing thickness ratios of $0.10 \leqslant t/c \leqslant 0.30$. Application of this method is illustrated in the sample problem on Page 4.1.3.2-8.

Non-Straight-Tapered Wings

Double-Delta Wings

Although the lift-curve slope near zero lift of double-delta wings is of little significance by itself, this C_{L_α} is used in the correlation of nonlinear lift of double-delta wings at subsonic speeds in Section 4.1.3.3.

This method, taken from Reference 9, consists of an extension of the method of Reference 3 by use of an effective value of $\cos \Lambda_{c/2}$, which is defined as the area-weighted average of the local value of $\cos \Lambda_{c/2}$.

The subsonic lift-curve slope of double-delta wings is obtained from the procedure outlined in the following steps:

Step 1. Divide the wing into n sections, each section being assumed to have constant sweep angles within its boundary. (See Section 2.2.2 for wing-geometry parameters.)

Step 2. Using the wing geometry determined in Step 1, obtain $(\cos \Lambda_{c/2})_{eff}$ by

$$\left(\cos \Lambda_{c/2}\right)_{eff} = \frac{1}{S_W} \sum_{j=1}^{j=n} (\cos \Lambda_{c/2})_j \, S_j \qquad 4.1.3.2\text{-f}$$

where

S_W is the total wing area.

j denotes one section of n sections having constant sweep angles within its boundary.

S_j is the total area of one section of n sections.

$(\cos \Lambda_{c/2})_j$ is the cosine of the sweep angle of the half-chord line of one section of n sections

Step 3. Obtain the lift-curve slope by application of the method used to determine C_{L_α} of straight-tapered wings, but with $(\Lambda_{c/2})_{eff}$ used in place of $\Lambda_{c/2}$ in the design chart (Figure 4.1.3.2-49).

Application of this technique is illustrated in the sample problem on Page 4.1.3.2-10.

Cranked Wings

The subsonic lift-curve slope of cranked wings with round-nosed airfoils is obtained by applying an empirical correlation to the method of Reference 9.

The equation for C_{L_α} of cranked wings, taken from Reference 8, is

$$C_{L_\alpha} = \left(C_{L_\alpha}\right)_{pred} \frac{\left(C_{L_\alpha}\right)_{test}}{\left(C_{L_\alpha}\right)_{pred}} \qquad 4.1.3.2\text{-g}$$

where

$\left(C_{L_\alpha}\right)_{pred}$ is the lift-curve slope of the cranked wing, predicted by the method outlined above for the double-delta planform.

$\frac{\left(C_{L_\alpha}\right)_{test}}{\left(C_{L_\alpha}\right)_{pred}}$ is the empirical correlation factor of subsonic lift-curve slope for cranked wings. It is presented as a function of wing aspect ratio and Mach number in Figure 4.1.3.2-52. (All cranked wings analyzed in Reference 8 had round leading edges, and the use of Figure 4.1.3.2-52 is restricted accordingly.)

A comparison of test data for 12 configurations with C_{L_α} of cranked wings having round-nosed airfoils calculated by this method is presented as Table 4.1.3.2-A (taken from Reference 8). The test data are for four wing-alone and eight wing-body configurations. Three of the wing-alone configurations have two breaks in the leading edge. Although no attempt has been made to define the effects of wing thickness ratio, poor accuracy generally results for $t/c > 0.09$. It should also be noted that the calculated accuracy deteriorates as Mach number exceeds 0.80. No configuration had a body-diameter-to-wing-span ratio greater than 0.147 and, consequently, the wing-body interference is considered to be negligible. It is suggested that this method be restricted to values of $M \leq 0.80$ and $t/c \leq 0.10$.

It is suggested that the subsonic lift-curve slope of cranked wings with sharp-nosed airfoils be obtained by direct application of the method outlined for double-delta planforms.

Curved Wings

No method is presented for estimating the subsonic lift-curve slope of curved wings because of their nonlinear lift characteristics.

Sample Problems

1. Method 2

Given: The following straight-tapered, constant-section, low-aspect-ratio, clipped-delta configuration.

$A = 0.823$ $\lambda = 0.18$ $\Lambda_{LE} = 73.5^\circ$ NACA 2412 airfoil

$M = 0.2$

Compute:

$$\left(C_{L_\alpha}\right)_{theory} = 8 \tan^{-1} \frac{\pi A}{16 + \pi A/(1 + 2\lambda \tan \Lambda_{LE})} \quad \text{(Equation 4.1.3.2-a)}$$

$$= 8 \tan^{-1} \frac{0.823\pi}{16 + 0.323\,\pi/[1 + 2(0.18)(3.376)]}$$

$$= 1.195 \text{ per rad} = 0.0209 \text{ per deg}$$

$$\frac{1}{3 + A}\left(\frac{1 - \lambda}{1 + 2\lambda}\right)^2 = \frac{1}{3 + 0.823}\left[\frac{1 - 0.18}{1 + 2(0.18)}\right]^2 = 0.0951$$

$$\frac{C_{L_\alpha}}{\left(C_{L_\alpha}\right)_{theory}} = 0.98 \quad \text{(Figure 4.1.3.2-50a)}$$

$$\left(C_{L_\alpha}\right)_{basic} = \left(C_{L_\alpha}\right)_{theory} \frac{C_{L_\alpha}}{\left(C_{L_\alpha}\right)_{theory}} \quad \text{(Equation 4.1.3.2-b)}$$

$$= (0.0209)(0.98)$$

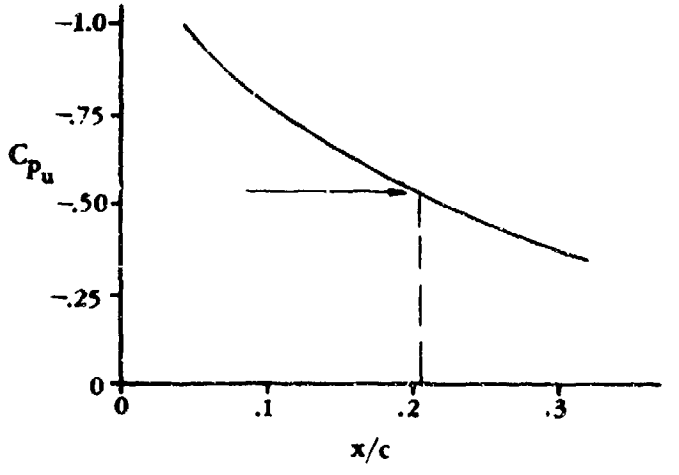
$$= 0.0205 \text{ per deg} \quad (\text{valid for } C_L < C_{L_{II}})$$

The following pressure data for a NACA 2412 airfoil are (Reference 11):

c_ℓ	C_{P_u}	x/c
0	−0.37	0.30
0.253	−0.56	0.19
0.5	−0.95	0.05

The above data are now plotted on Figure 4.1.3.2-50b. From Figure 4.1.3.2-50b we now obtain a value of 0.222 for $C_{L_{II}}$ at a value of −0.53 for C_{P_u}.

Plot C_{P_u} versus x/c



From the above plot x/c = 0.204 for C_{P_u} = −0.53.

$$\frac{x/c}{(1+\lambda)(1-x/c)\tan\Lambda_{LE}} = \frac{0.204}{(1+0.18)(1-0.204)(3.376)} = 0.0643$$

$C_{L_{III}} = 0.467$ (Figure 4.1.3.2-51)

$\Lambda_c = 90^o - \Lambda_{LE} = 90^o - 73.5^o = 16.5^o$

$\left(C_{L_\alpha}\right)_{limit} = 0.0467 (\sin \Lambda_c)^{1/4}$ (Equation 4.1.3.2-c)

$= 0.0467 (\sin 16.5^o)^{1/4}$

$= 0.0342$ per deg

$\left(C_{L_\alpha}\right)_{limit} - \left(C_{L_\alpha}\right)_{basic} = 0.0342 - 0.0205 = 0.0137$

Since $0.0137 > 0.0067$, $\left(\delta C_{L_\alpha}\right)_{II} = 0.0067$ (Step 7)

$\left(C_{L_\alpha}\right)_{II} = \left(C_{L_\alpha}\right)_{basic} + \left(\delta C_{L_\alpha}\right)_{II}$ (Equation 4.1.3.2-d)

$= 0.0205 + 0.0067$

$= 0.0272$ per deg (valid for $0.222 \leq C_L \leq 0.467$)

Since $0.0137 > 0.012$, $\delta C_{L_{\alpha III}} = 0.012$ per deg (Step 9)

$\left(C_{L_\alpha}\right)_{III} = \left(C_{L_\alpha}\right)_{basic} + \left(\delta C_{L_\alpha}\right)_{III}$ (Equation 4.1.3.2-e)

$= 0.0205 + 0.012$

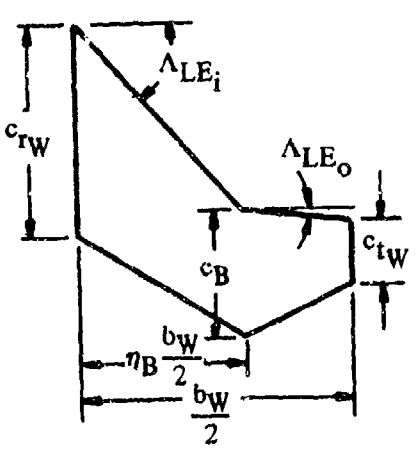
$= 0.0325$ per deg (valid for $C_L > 0.467$)

Solution:

The entire lift curve can now be constructed assuming the wing zero-lift angle of attack α_0 has been determined using Section 4.1.3.1.

2. Non-Straight-Tapered Wings

Given: The cranked-wing planform of Reference 29. (See Section 2.2.2 for wing-planform geometry.)



$A_W = 4.0$ $S_W = 2.25$ sq ft $b_W/2 = 18.0$ in.

$\eta_B = 0.6$ $S_i = 1.641$ sq ft $S_o = 0.609$ sq ft

$c_{r_W} = 13.85$ in. $c_B = 8.03$ in. $c_{t_W} = 4.15$ in.

$\lambda_W = 0.30$ $\lambda_i = 0.58$ $\lambda_o = 0.517$

$\Lambda_{LE_i} = 48.6^o$ $\Lambda_{LE_o} = 7.7^o$

$\Lambda_{c/2_i} = 40.9^o$ $\Lambda_{c/2_o} = -7.7^o$

NACA 65A006 airfoil $M = 0.80$; $\beta = 0.60$

Compute:

$$(\cos \Lambda_{c/2})_{eff} = \frac{1}{S_W} \sum_{j=1}^{j=n} (\cos \Lambda_{c/2})_j S_j = \frac{1}{S_W} \left[(\cos \Lambda_{c/2})_i S_i + (\cos \Lambda_{c/2})_o S_o \right]$$

(Equation 4.1.3.2-f)

$$= \frac{1}{2.25} \left[(0.756)(1.641) + (0.991)(0.609) \right] = 0.820$$

$$(\Lambda_{c/2})_{eff} = 34.9^o \; ; \tan (\Lambda_{c/2})_{eff} = 0.6976$$

$$c_{\ell_\alpha} = 6.00 \text{ per rad (Section 4.1.1)}$$

$$c_{\ell_{\alpha_M}} = \frac{c_{\ell_\alpha}}{\beta} = \frac{6.00}{0.6} = 10.0 \text{ per rad}$$

$$\kappa = \frac{c_{\ell_{\alpha_M}}}{(2\pi/\beta)} = \frac{10.0\,(0.6)}{2\pi} = 0.955$$

$$\frac{A}{\kappa} \left[\beta^2 + \tan^2 (\Lambda_{c/2})_{eff} \right]^{1/2} = \frac{4.0}{0.955} \left[0.36 + 0.4866 \right]^{1/2} = 3.85$$

$$\frac{(C_{L_\alpha})_{pred}}{A} = 1.00 \text{ per rad (Figure 4.1.3.2-49)}$$

$$(C_{L_\alpha})_{pred} = 4.00 \text{ per rad}$$

$$\beta A = (0.6)(4.0) = 2.40$$

$$\frac{(C_{L_\alpha})_{test}}{(C_{L_\alpha})_{pred}} = 1.081 \text{ (Figure 4.1.3.2-52)}$$

Solution:

$$C_{L_\alpha} = (C_{L_\alpha})_{pred} \frac{(C_{L_\alpha})_{test}}{(C_{L_\alpha})_{pred}} \text{ (Equation 4.1.3.2-g)}$$

$$= (4.00)(1.081)$$

$$= 4.324 \text{ per rad}$$

$$= 0.0755 \text{ per deg}$$

This compares with a test value of 0.075 per degree from Reference 29.

B. TRANSONIC

The transonic characteristics of wings are very difficult to predict. The current status of the problem is summarized in Reference 12. It is pointed out in this reference that although transonic theory gives results of surprisingly good accuracy in many cases, the mathematical difficulties in solving nonlinear partial differential equations of the mixed elliptic-hyperbolic type have limited its application to a few simple configurations.

On the other hand, wind-tunnel tests cover a wide variety of configurations but are of questionable accuracy because of wall-interference effects. These interference effects are both difficult to determine analytically and difficult to eliminate. Simply testing smaller models is not always sufficient, even in slotted-wall tunnels (Reference 12).

In spite of the uncertainties in test data, the straight-tapered-wing design charts of this section are based largely on experimental data from wind-tunnel tests. This is done because of certain important flow-separation effects not accounted for by theory and because of the limited scope of existing solutions for transonic theory. The limited experimental data for non-straight-tapered wings preclude development of design methods for those planforms at transonic speeds. However, a chart is presented that indicates the trend of transonic data for double-delta wings and for cranked wings with an aspect ratio of approximately three.

Thick, unswept, straight-tapered wings show increases in lift-curve slope with Mach number up to Mach numbers slightly beyond the critical. The slope then drops abruptly to a low value followed by a rise near Mach=1.0 to a value almost as high as the value at the critical Mach number (see Sketch (c), for type "A" wings). This behavior for two-dimensional sections is illustrated in References 13, 14, and 15. Reducing either the aspect ratio or the wing-thickness ratio or both reduces the magnitude of these effects. For very thin wings and for wings of very low aspect ratio these transonic nonlinearities do not exist (see Sketch (c) for type "B" wings). Increasing the sweep angle raises the wing critical Mach number. However, the increase is never as large as that predicted by simple sweep theory. Reference 16 shows that three-dimensional effects in the regions of the wing root and tip prevent the full benefits of sweep from being realized.

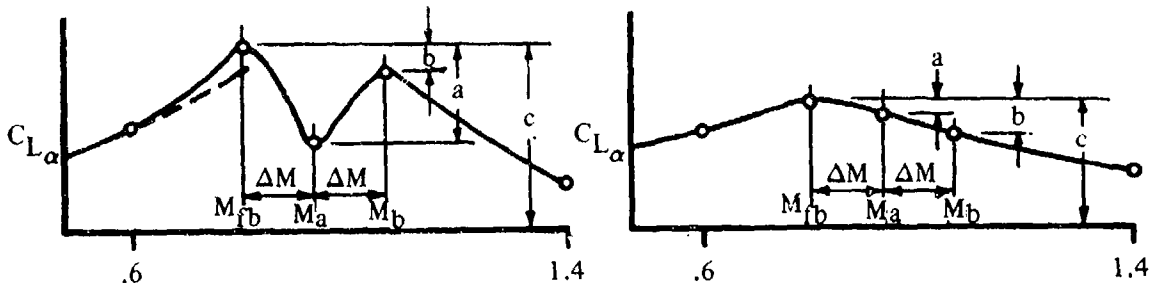
The transonic nonlinearities in lift-curve slope are related to the appearance of local shocks located asymmetrically on the upper and lower surfaces of the wing. Prediction of the exact shock-wave location is somewhat involved, since there is an interaction between the shocks on the upper and lower surfaces (Reference 17). Camber, thickness ratio, and thickness distribution all have pronounced effects on section transonic lift characteristics. Proper combination of the above geometric parameters can prevent transonic lift losses even for quite thick sections (Reference 18). Wings that do have large transonic lift losses at zero angle of attack show marked recovery at higher angles of attack (Reference 19).

DATCOM METHODS

Straight-Tapered Wings

The procedure for constructing the transonic lift-curve slope of conventional planforms is outlined in the following steps. In following this procedure, reference should be made to the schematic sketch below. The method is based on data for the untwisted and uncambered wings of References 19 and 47 through 51. These data are compared in Table 4.1.3.2-B with the values calculated from the charts.

The charts are limited to wings having symmetrical airfoils of conventional thickness distribution and are for zero angle of attack only.



SKETCH (c)

Step 1. Calculate the force-break Mach number M_{fb}. This is obtained from Figure 4.1.3.2-53a for zero wing sweep. A correction for sweep effects is provided by Figure 4.1.3.2-53b.

Step 2. Compute the theoretical lift-curve slope at the force-break Mach number by the method of paragraph A.

Step 3. The actual lift-curve slope at the force-break Mach number is found by means of the ratio $\left(C_{L_\alpha}\right)_{fb}/\left(C_{L_\alpha}\right)_{theory}$ obtained from Figure 4.1.3.2-54a.

Step 4. The abrupt decrease in lift-curve slope above the force-break Mach number is described by the ratio a/c (see Sketch (c)). This ratio is given in Figure 4.1.3.2-54b. The Mach number M_a at which the lift-curve slope reaches its minimum value is

$$M_a = M_{fb} + 0.07$$

The lift-curve slope at M_a is

$$\left(C_{L_\alpha}\right)_a = \left(1 - \frac{a}{c}\right)\left(C_{L_\alpha}\right)_{fb}$$

For wings that do not exhibit large transonic lift losses (Sketch (c)), the lift-curve slope at M_a may still be obtained from the ratio a/c as given in Figure 4.1.3.2-54b. In all cases, c is the lift-curve slope at the force-break Mach number as obtained in Step 3.

Step 5. The subsequent rise in C_{L_α} (Sketch (b)) is given by the ratio b/c as presented in Figure 4.1.3.2-54c. The Mach number at this point is

$$M_b = M_{fb} + 0.14$$

The lift-curve slope is

$$\left(C_{L_\alpha}\right)_b = \left(1 - \frac{b}{c}\right)\left(C_{L_\alpha}\right)_{fb}$$

An identical procedure is used for wings of type "B."

Step 6. The lift-curve slope at M = 0.6 is calculated by the straight-tapered-wing method of Paragraph A of this section.

Step 7. The lift-curve slope at M = 1.4 is calculated by the straight-tapered-wing method of Paragraph C of this section.

Step 8. The complete transonic lift-curve slope between Mach numbers 0.6 and 1.4 can now be constructed by fairing a curve through the points obtained by means of Steps 1 through 7.

Non-Straight-Tapered Wings

During the course of the program reported in Reference 8 an empirical correlation of the lift-curve slope of double-delta and cranked wings at M = 1.0 was achieved. This correlation is presented herein as Figure 4.1.3.2-55. It is suggested that it be used as a guide for fairing between subsonic and supersonic values of C_{L_α} of composite wings with an aspect ratio of three or less.

The configurations used in the correlation vary in aspect ratio from 1.33 to 3.0. The inboard-panel sweepback is 78° for the lower correlation points and 60° for the upper correlation points. Spanwise positions of the leading-edge break η_B vary from approximately 0.30 to 0.70.

Sample Problems

1. Straight-Tapered Wing of Type "A."

Given: Wing tested in Reference 48.

A = 4.0 $\quad \lambda = 1.0 \quad \Lambda_{LE} = 0$ NACA 63A010 airfoil

Compute:

M_{fb} = 0.842 (Figure 4.1.3.2-53a)

$\left(C_{L_\alpha}\right)_{theory}$ at M_{fb}

c_{ℓ_α} = 6.02 per rad (Section 4.1.1)

$$c_{\ell_{\alpha_M}} = \frac{c_{\ell_\alpha}}{\beta}$$

$$\kappa = \frac{c_{\ell_{\alpha_M}}}{(2\pi/\beta)} = \frac{\left(c_{\ell_\alpha}/\beta\right)}{(2\pi/\beta)} = \frac{c_{\ell_\alpha}}{2\pi} = 0.958$$

$$\frac{A}{\kappa}\left[\beta^2_{fb} + \tan^2 \Lambda_{c/2}\right]^{1/2} = \frac{4.0}{0.958}(0.291)^{1/2} = 2.25$$

$$\frac{\left(C_{L_\alpha}\right)_{theory}}{A} = 1.25 \text{ per rad (Figure 4.1.3.2-49)}$$

$$\left(C_{L_\alpha}\right)_{theory} = 5.0 \text{ per rad}$$

$$\frac{\left(C_{L_\alpha}\right)_{fb}}{\left(C_{L_\alpha}\right)_{theory}} = 0.96 \text{ (Figure 4.1.3.2-54a)}$$

$$\left(C_{L_\alpha}\right)_{fb} = 4.80 \text{ per rad}$$

$$\frac{a}{c} = 0.35 \text{ (Figure 4.1.3.2-54b)}$$

$$M_a = M_{fb} + 0.07 = 0.912$$

$$\left(C_{L_\alpha}\right)_a = \left(1 - \frac{a}{c}\right)\left(C_{L_\alpha}\right)_{fb} = 3.12 \text{ per rad}$$

$$\frac{b}{c} = 0.15 \text{ (Figure 4.1.3.2-54c)}$$

$$M_b = M_{fb} + 0.14 = 0.982$$

$$\left(C_{L_\alpha}\right)_b = \left(1 - \frac{b}{c}\right)\left(C_{L_\alpha}\right)_{fb} = 4.08 \text{ per rad}$$

$\left(C_{L_\alpha}\right)_{M=0.6}$ (Paragraph A)

$$\frac{A}{\kappa}\left[\beta^2 + \tan^2 \Lambda_{c/2}\right]^{1/2} = \frac{4.0}{0.958}(0.64)^{1/2} = 3.34$$

$$\frac{\left(C_{L_\alpha}\right)_{M=0.6}}{A} = 1.065 \text{ per rad (Figure 4.1.3.2-49)}$$

$$\left(C_{L_\alpha}\right)_{M=0.6} = 4.26 \text{ per rad}$$

$\left(C_{L_\alpha}\right)_{M=1.40}$ (Paragraph C)

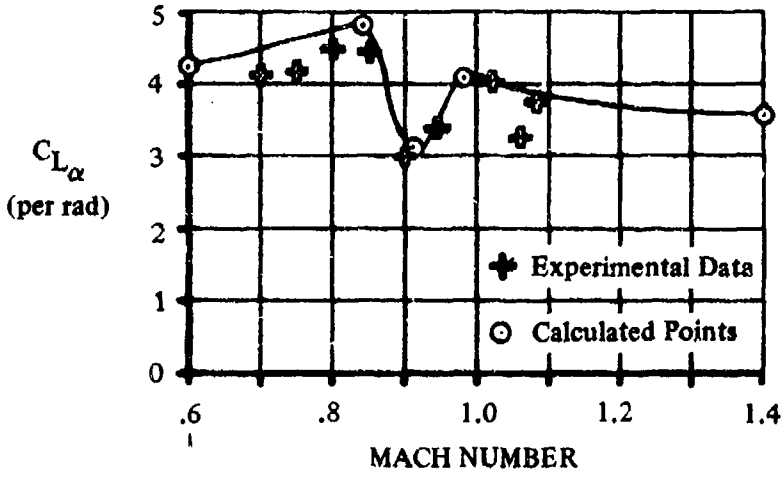
$$1/(\beta A) = 0.255$$

βC_{N_α} = 3.50 per rad (Figure 4.1.3.2-56g)

$\left(C_{N_\alpha}\right)_{M=1.4}$ = 3.57 per rad

Solution:

The complete lift-curve slope as a function of Mach number may now be constructed as shown in the following diagram.



2. Straight-Tapered Wing of Type "B"

Given: Wing tested in Reference 47.

A = 2.67 λ = 0.2 Λ_{LE} = 45° NACA 63A004 airfoil

Compute:

$(M_{fb})_{\Lambda=0}$ = 1.00 (Figure 4.1.3.2-53a)

$\Lambda_{c/2}$ = 26.6°

$(M_{fb})_\Lambda$ = 1.00 (Figure 4.1.3.2-53b)

$\left(C_{L_\alpha}\right)_{theory}$ at $(M_{fb})_\Lambda$

c_{ℓ_α} = 6.47 per rad (Section 4.1.1.2)

$$c_{\ell_{\alpha_M}} = \frac{c_{\ell_\alpha}}{\beta}$$

$$\kappa = \frac{c_{\ell_{\alpha_M}}}{(2\pi/\beta)} = \frac{\left(c_{\ell_\alpha}/\beta\right)}{(2\pi/\beta)} = \frac{c_{\ell_\alpha}}{2\pi} = 1.03$$

$$\frac{A}{\kappa}\left[(\beta_{fb})\Lambda^2 + \tan^2 \Lambda_{c/2}\right]^{1/2} = \frac{2.67}{1.03}(0.251)^{1/2} = 1.30$$

$$\frac{\left(C_{L_\alpha}\right)_{theory}}{A} = 1.435 \text{ per rad (Figure 4.1.3.2-49)}$$

$$\left(C_{L_\alpha}\right)_{theory} = 3.83 \text{ per rad}$$

$$\frac{\left(C_{L_\alpha}\right)_{fb}}{\left(C_{L_\alpha}\right)_{theory}} = 1.085 \text{ (Figure 4.1.3.2-54a)}$$

$$\left(C_{L_\alpha}\right)_{fb} = 4.16 \text{ per rad}$$

$$\frac{a}{c} = 0.005 \text{ (Figure 4.1.3.2-54b)}$$

$$M_a = M_{fb} + 0.07 = 1.07$$

$$\left(C_{L_\alpha}\right)_a = \left(1 - \frac{a}{c}\right)\left(C_{L_\alpha}\right)_{fb} = 4.14 \text{ per rad}$$

$$\frac{b}{c} = 0.075 \text{ (Figure 4.1.3.2-54c)}$$

$$M_b = M_{fb} + 0.14 = 1.14$$

$$\left(C_{L_\alpha}\right)_b = \left(1 - \frac{b}{c}\right)\left(C_{L_\alpha}\right)_{fb} = 3.85$$

$\left(C_{L_\alpha}\right)_{M=0.6}$ (Paragraph A)

$$\frac{A}{\kappa}\left[\beta^2 + \tan^2 \Lambda_{c/2}\right]^{1/2} = \frac{2.67}{1.03}\left[0.64 + 0.251\right]^{1/2} = 2.45$$

$$\frac{\left(C_{L_\alpha}\right)_{M=0.6}}{A} = 1.22 \text{ per rad (Figure 4.1.3.2-49)}$$

$$\left(C_{L_\alpha}\right)_{M=0.6} = 3.26 \text{ per rad}$$

$\left(C_{L_\alpha}\right)_{M=1.4}$ (Paragraph C)

$\beta/\tan \Lambda_{LE}$ = 0.98; A $\tan \Lambda_{LE}$ = 2.67

$\tan \Lambda_{LE} \left(C_{N_\alpha}\right)_{theory}$ = 3.55 per rad (Figure 4.1.3.2-56b)

$\left(C_{N_\alpha}\right)_{theory}$ = 3.55 per rad

Δy = 0.88 (Figure 2.2.1-8)

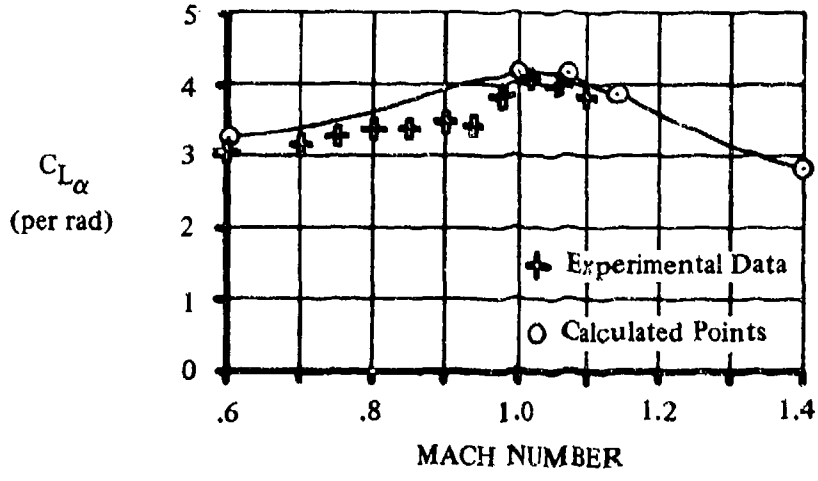
$\Delta y_\perp = \dfrac{\Delta y}{\cos \Lambda_{LE}}$ = 1.245

$\dfrac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}}$ = 0.795 (Figure 4.1.3.2-60)

$\left(C_{N_\alpha}\right)_{M=1.4}$ = 2.82 per rad

Solution:

The complete lift-curve slope as a function of Mach number may now be constructed as shown in the following diagram.



C. SUPERSONIC

Methods are presented for determining the wing normal-force-curve slope of the following two classes of wing planforms:

Straight-Tapered Wings (conventional, fixed trapezoidal wings)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

These three general categories of non-straight-tapered wings are illustrated in Sketch (a) (paragraph A). Their wing-geometry parameters are presented in Section 2.2.2.

At supersonic speeds, the normal-force-curve slope C_{N_α} of conventional, double-delta, and cranked wings is adequately predicted by theoretical calculations except where the effects of thickness become important.

The design charts pertaining to these wing planforms are based on the following references:

Reference 20 – in the region of supersonic leading and trailing edges

Reference 21 – in the region of subsonic leading edges and supersonic trailing edges

Reference 22 – in the regions of tip-root interaction and tip-tip interaction

Reference 23 – in the region of subsonic leading and trailing edges

Reference 6 – for values of $A\beta \leq 1/4$ and $\sigma \leq 1.0$ where $\sigma = 1/4[A(1+\lambda)\tan \Lambda_{LE}]$

References 24 and 25 – for values of $A\beta \leq 1/4$ and $\sigma \geq 1.0$

In addition, an empirically determined "lift-interference factor" from Reference 8 is applied to correlate the results for double-delta and cranked wings. The theoretical results are based on linear theory with the exception of the region where $A\beta \leq 1/4$, which is based on slender-wing theory. Thin airfoils have been assumed in these theories. Thickness effects are not important except for conditions where the Mach lines lie on or near the wing leading edge. Under these conditions the wing-leading-edge shock position is displaced forward from its theoretical position by the finite thickness effects of the leading edge. This displacement results in substantial losses in normal-force-curve slope.

For straight-tapered wings with sharp leading edges, the airfoil nose semiwedge angle (measured perpendicular to the wing leading edge) determines the shock position relative to the wing and hence the normal-force-curve slope. Experimental data indicate that the parameter corresponding to the nose semiwedge angle of the supersonic airfoil is $\Delta y/\cos \Lambda_{LE}$, where Δy is the difference between the upper-surface ordinates expressed in percent chord at the 6-percent- and 0.15-percent-chord stations (Figure 2.2.1-8). This is the same Δy discussed in Section 4.1.3.4 with regard to

airfoil maximum lift. It can be shown that for double-wedge and biconvex airfoils there is a linear relationship between Δy and the leading-edge semiwedge angle, given by

$$\Delta y_{\perp} = 5.85 \tan \delta_{\perp}$$

where

$$\Delta y_{\perp} = \frac{\Delta y}{\cos \Lambda_{LE}}$$

and $\delta_{\perp}$ is the semiwedge angle normal to the leading edge. Either $\delta_{\perp}$ or $\Delta y_{\perp}$, whichever is more convenient, may be used to calculate thickness effects for straight-tapered wings with sharp-nosed airfoils.

Figure 4.1.3.2-60 presents the leading-edge-thickness effect on the normal-force-curve slope of straight-tapered wings in the form of a ratio of actual normal-force-curve slope to theoretical normal-force-curve slope. This chart is empirically derived from the experimental data of Reference 26 of this section and References 11 through 17, 26, and 45, of Section 4.1.3.3.

For double-delta and cranked wings empirical correlation factors for round-nosed and sharp-nosed airfoils (from Reference 8) are applied, which account for leading-edge effects.

The method presented for determining the normal-force-curve slope of curved (Gothic and ogee) wings consists of a semiempirical correlation based on the theoretical results of Squire in Reference 27.

Because of the nonlinear nature of the normal-force curve at high angles of attack, the methods presented for estimating C_{N_α} are limited to low angles of attack.

Wings with inverse taper ($\lambda > 1$) have not been considered. Wings with swept-forward leading edges are included through the use of the reversibility theorem (Reference 28). The reversibility theorem states that the normal-force-curve slope of the wing in forward flight equals the normal-force-curve slope of the same wing in reverse flight at the same Mach number.

DATCOM METHODS

Straight-Tapered Wings

The supersonic normal-force-curve slope of conventional wings is obtained as outlined in the following steps:

Step 1. Obtain the theoretical normal-force-curve slope from Figures 4.1.3.2-56a through 4.1.3.2-56f, except for rectangular wings. The theoretical normal-force-curve slope for rectangular wings must be obtained from Figure 4.1.3.2-56g. These charts should be used for $M \geq 1.4$. For Mach numbers less than 1.4 the transonic method of Paragraph B should be used.

Step 2. For wings approaching the sonic-leading-edge condition, the theoretical C_{N_α} value obtained from Step 1 should be multiplied by the empirical thickness correction factor from Figure 4.1.3.2-60.

Non-Straight-Tapered Wings

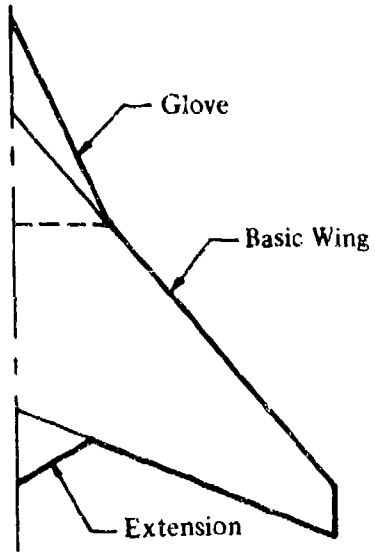
Double-Delta Wings

This method, taken from Reference 8, uses the linear-theory design charts of the straight-tapered-wing method with appropriate empirical correction factors. Application of the method requires that the wing planform be broken down as follows (see Sketch (d)):

Basic Wing – the outboard leading and trailing edges extended to the center line.

Glove – a delta wing superimposed over the basic wing. The glove leading edge is that of the inboard panel.

Extension – that portion of the wing behind the trailing edge of the basic wing for wings with broken trailing edges.



SKETCH (d)

The method is applicable to double-delta wings having breaks in the leading- and/or trailing-edge sweep at only one spanwise station.

The normal-force-curve slope of the total wing is

$$C_{N_\alpha} = K_L \left[\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} \left(C_{LE}\right)_{bw} + \left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} \left(C_{LE}\right)_g + \left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} \right] \qquad 4.1.3.2\text{-n}$$

where

K_L is an empirically derived "lift-interference factor" obtained from Figure 4.1.3.2-61.

$\frac{S_{bw}}{S_W}, \frac{S_g}{S_W}, \frac{S_E}{S_W}$ are the ratios of the areas of the basic wing, glove, and trailing-edge extension, respectively, to the total wing area. (See Section 2.2.2 for wing-geometry parameters.)

$(C_{N_\alpha})_{bw}, (C_{N_\alpha})_g$ are the normal-force-curve slopes of the basic wing and glove, respectively. $(C_{N_\alpha})_{bw}$ is obtained from Figures 4.1.3.2-56a through 4.1.3.2-56f. $(C_{N_\alpha})_g$ is obtained from either Figure 4.1.3.2-56a or Figure 4.1.3.2-63.

$(C_{LE})_{bw}, (C_{LE})_g$ are empirically derived "leading-edge-effect factors" obtained from Figure 4.1.3.2-62 as functions of Mach number and the respective planform leading-edge sweepback.

$(C_{N_\alpha})_E$ is the normal-force-curve slope of the trailing-edge extension, shown schematically in Sketch (e), and is given by

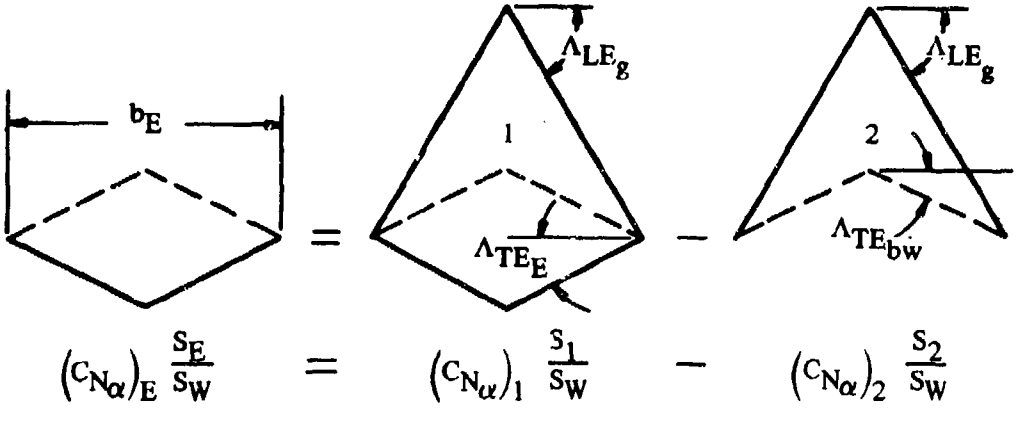
$$(C_{N_\alpha})_E = \frac{(C_{N_\alpha})_1 \frac{S_1}{S_W} - (C_{N_\alpha})_2 \frac{S_2}{S_W}}{S_E/S_W} \qquad 4.1.3.2\text{-i}$$

where

$(C_{N_\alpha})_1$ is the normal-force-curve slope of a zero-taper-ratio wing with $\Lambda_{LE} = \Lambda_{LE_g}$ and $\Lambda_{TE} = \Lambda_{TE_E}$, obtained from Figure 4.1.3.2-56a or Figure 4.1.3.2-63.

$(C_{N_\alpha})_2$ is the normal-force-curve slope of a zero-taper-ratio wing with $\Lambda_{LE} = \Lambda_{LE_g}$ and $\Lambda_{TE} = \Lambda_{TE_{bw}}$, obtained from Figure 4.1.3.2-56a or Figure 4.1.3.2-63.

$\frac{S_1}{S_W}, \frac{S_2}{S_W}$ are the ratios of the areas of the two zero-taper planforms to the total wing area.



SKETCH (e)

It is recommended that Figure 4.1.3.2-63 be used to obtain the normal-force-curve slopes of the zero-taper-ratio wings rather than Figure 4.1.3.2-56a because of the upper limit of the parameter A tan Λ_{LE} of Figure 4.1.3.2-56a. The use of Figure 4.1.3.2-63 is very convenient since the normal-force-curve slope is presented in the form C_{N_α}/A, which eliminates the necessity of calculating the area of each individual panel.* All that is required to solve Equation 4.1.3.2-i is the total wing planform area S_W and the span b_E of the trailing-edge extension. Using values of C_{N_α}/A from Figure 4.1.3.2-63, Equation 4.1.3.2-i becomes

$$\left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} = \left[\left(\frac{C_{N_\alpha}}{A}\right)_1 - \left(\frac{C_{N_\alpha}}{A}\right)_2\right] \frac{b_E^2}{S_W} \qquad 4.1.3.2\text{-j}$$

Application of this method is illustrated in Sample Problem 1 on Page 4.1.3.2-29.

A comparison of test data for 26 configurations with C_{N_α} of double-delta wings calculated by this method is presented as Table 4.1.3.2-C (taken from Reference 8). All but two of the configurations listed in the table are wing-body combinations, All predictions were made by using the theoretical planform (leading and trailing edges extended to the center line) for the total planform area and neglecting body effects. No configuration had a ratio of body diameter to wing span greater than 0.15; consequently, the wing-body interference is considered to be negligible. The wing-thickness-ratio range covered (0.02 to 0.07) is consistent with current practice and no significant effects of wing thickness ratio are evident.

It should be noted that the maximum error generally occurs on wing-body configurations with large inboard sweep angles ($\Lambda_{LE_i} > 78^\circ$). This can conceivably result from two sources. Configurations with large inboard sweep have a large portion of the theoretical glove planform submerged in the body, making the assumption of negligible wing-body interference effects less valid; and the "leading-edge-effect factors" presented in Figure 4.1.3.2-62 are not well defined for sharp-nosed airfoils at low values of $\beta/\tan \Lambda_{LE}$.

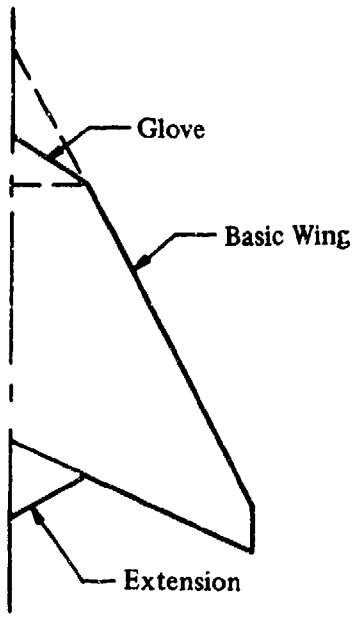
It is recommended that this method be restricted to the Mach-number range, $1.2 \leq M \leq 3.0$ For $M = 1.0$ the empirical correlation presented in Paragraph B should be used.

Another class of double-delta wings of practical interest are those with the outboard wing sweep greater than the inboard wing sweep. No configuration with $\Lambda_{LE_o} > \Lambda_{LE_i}$ was analyzed during the investigation reported in Reference 8; however, a method of approach for treating such configurations is suggested.

Defining the basic-wing breakdown as before results in some additional basic-wing area created forward of the wing sweep break as illustrated in Sketch (f).

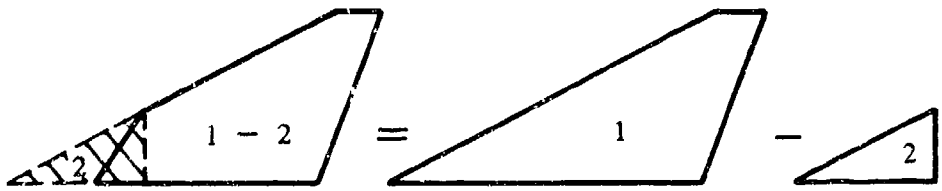
*Figure 4.1.3.2-63 may also be applied with equal facility to obtain normal-force-curve slope of the glove. Using $(C_{N_\alpha}/A)_g$ from Figure 4.1.3.2-63

$$\left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} = \left(\frac{C_{N_\alpha}}{A}\right)_g \frac{b_g^2}{S_W}$$



SKETCH (f)

For this class of double-delta wings the normal-force-curve slope of the basic wing is determined by extending the basic-wing leading edge to the configuration center line, calculating the normal-force-curve slope of the extended basic-wing panel, and calculating and subtracting the normal-force-curve slope of the section of the basic-wing panel forward of the wing sweep break. This is shown schematically in Sketch (g).



$$\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} = \left(C_{N_\alpha}\right)_1 \frac{S_1}{S_W} - \left(C_{N_\alpha}\right)_2 \frac{S_2}{S_W}$$

SKETCH (g)

Based on this definition of the normal-force-curve slope of the basic wing, the total wing normal-force-curve slope is given by Equation 4.1.3.2-h with the "lift-interference factor" K_L replaced by K.

$$C_{N_\alpha} = K \left[\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} (C_{LE})_{bw} + \left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} (C_{LE})_g + \left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} \right] \qquad 4.1.3.2\text{-k}$$

where

K is an empirical correlation factor which corresponds to the "lift-interference factor" K_L. Not enough force data are available to allow correlation of this parameter; however, based on a limited amount of experimental rolling-moment data, K appears to be approximately one.

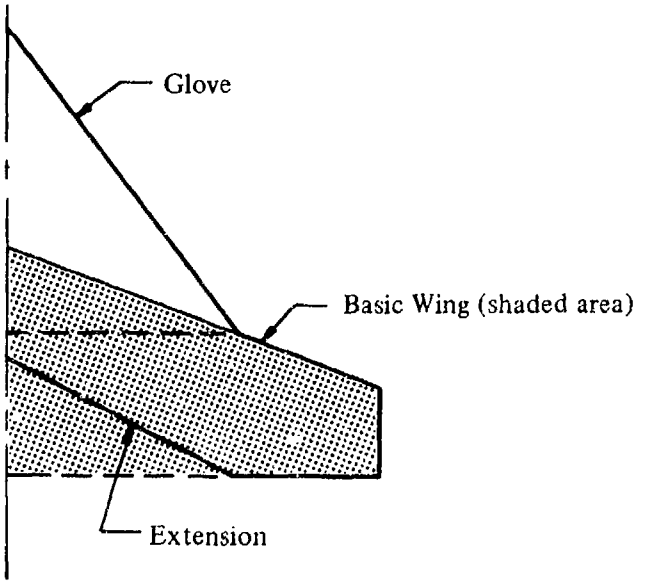
The remaining parameters are defined as before.

Although not enough data are available to substantiate application of the foregoing analysis to double-delta planforms with $\Lambda_{LE_o} > \Lambda_{LE_i}$, it can be concluded that the method will become less valid for wings employing sharp-nosed airfoils and large outboard sweep angles, since the "leading-edge-effect factors" are not well defined for wings with sharp-nosed airfoils at low values of $\beta/\tan \Lambda_{LE}$.

Application of this method is illustrated in Sample Problem 2 on Page 4.1.3.2-32.

Cranked Wings

The method used to predict the normal-force-curve slope of double-delta wings is also applicable to cranked wings. However, for cranked wings with broken trailing edges the inboard trailing-edge sweep angle may be greater than the outboard trailing-edge sweep angle. Since the basic wing is defined as in the double-delta wing breakdown, this results in some additional area being created behind the inboard trailing edge as illustrated in Sketch (h).



Cranked wing with $\Lambda_{TE_i} > \Lambda_{TE_o}$

SKETCH (h)

This additional area is considered to be the trailing-edge extension. Defining $(C_{N_\alpha})_1$ and $(C_{N_\alpha})_2$ exactly as for the double-delta wing results in a negative normal-force-curve increment for the trailing-edge extension.

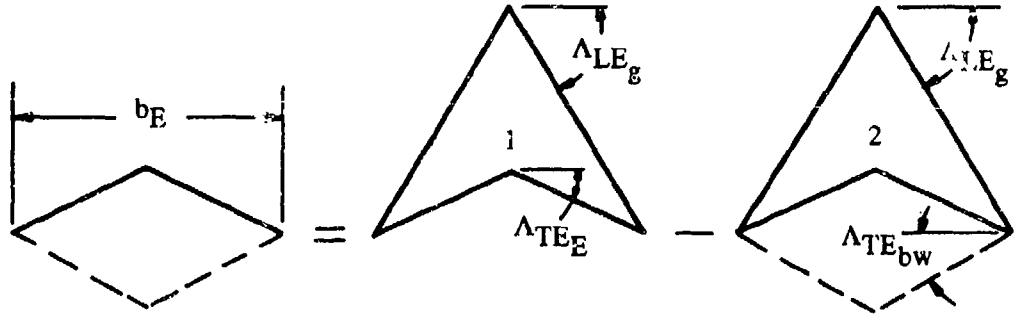
This method is applicable to cranked wings having breaks in the leading- and/or trailing-edge sweep at only one spanwise station.

The normal-force-curve slope of the total wing is given by Equation 4.1.3.2-h; i.e.,

$$C_{N_\alpha} = K_L \left[\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} (C_{LE})_{bw} + \left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} (C_{LE})_g + \left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} \right]$$

where all the parameters are defined under Equation 4.1.3.2-h of the double-delta-wing method.

The normal-force-curve slope of the trailing-edge extension for the case where the inboard trailing-edge sweep angle is greater than the outboard trailing-edge sweep angle is shown schematically in Sketch (i).



$$\left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} = \left(C_{N_\alpha}\right)_1 \frac{S_1}{S_W} - \left(C_{N_\alpha}\right)_2 \frac{S_2}{S_W}$$

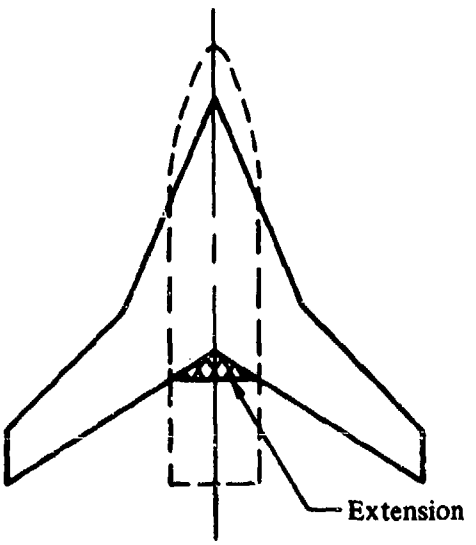
SKETCH (i)

Application of this technique is illustrated in Sample Problem 3 on Page 4.1.3.2-34.

A comparison of test data for seven configurations with C_{N_α} of cranked wings calculated by this method is presented as Table 4.1.3.2-D (taken from Reference 8). The configurations listed in the table are either wing-body combinations or wing-body combinations with nacelles included in the body. The inboard leading-edge sweep angles are generally lower than those on the double-delta wings, which would tend to alleviate the body effects on the glove discussed under the

double-delta-wing method. The wing thickness-ratio range covered (0.02 to 0.08) is consistent with current practice and no significant effects of wing thickness ratio are evident.

Five of the configurations had small ratios of body diameter to wing span and the predictions for those configurations were based on the theoretical planform extended to the body center line. The configurations of References 65 and 66 had nacelles included in the body, and an effective extension was included as part of the planform as shown in Sketch (j). Since the definition of the extension was somewhat arbitrary, this technique should not be considered as a general wing-body prediction technique.



SKETCH (j)

Although all the configurations investigated had round-nosed airfoils, the application of the method to cranked wings with sharp-nosed airfoils should give equally good results except in the low supersonic Mach-number range. The "leading-edge-effect factors" are not well defined for sharp-nosed airfoils at low values of $\beta/\tan \Lambda_{LE}$ and must be considered as a possible source of error at low supersonic Mach numbers.

It is recommended that this method be restricted to the Mach number range, $1.2 \leq M \leq 3.0$. For $M = 1.0$ the empirical correlation presented in Paragraph B can be used for cranked wings with aspect ratios of approximately three.

Curved Wings

This method, taken from Reference 8, is based on the theoretical results of Squire in Reference 27.

The supersonic normal-force-curve slope of curved (Gothic and ogee) planforms is obtained from the procedure outlined in the following steps:

Step 1. Using the given wing geometry calculate the aspect ratio A, the planform shape parameter p, and the wing slenderness parameter $b_W/(2\ell)$. (See Section 2.2.2 for wing-geometry parameters.)

Step 2. At the desired value of $\frac{\beta b_W}{2\ell}$ obtain $\left(\frac{C_{N_\alpha}}{A}\right)\left(\frac{1+p}{p}\right)$ from Figure 4.1.3.2-64.

Step 3. Calculate the supersonic normal-force-curve slope by

$$C_{N_\alpha} = \left[\left(\frac{C_{N_\alpha}}{A}\right)\left(\frac{1+p}{p}\right)\right] A \left(\frac{p}{1+p}\right) \qquad 4.1.3.2\text{-}l$$

Application of this method is illustrated in Sample Problem 4 on Page 4.1.3.2-36.

A comparison of test data for 18 configurations with C_{N_α} of curved wings calculated by this method is presented as Table 4.1.3.2-E (taken from Reference 8). Four of the configurations listed in the table are wing-body combinations with small ratios of body diameter to wing span. The calculations for these configurations were made by using the theoretical planform extended to the body center line and neglecting body effects. All models employed thin wings ($0.008 \leqslant t/c \leqslant 0.06$) with sharp leading edges.

The method provides satisfactory results for low supersonic Mach numbers and may be applied over the Mach number range, $1.0 \leqslant M \leqslant 3.0$.

On some ogee-wing-body configurations the leading-edge sweep becomes very large near the wing-body juncture. For such configurations, unrealistic values of p will be obtained if "good engineering judgment" is not exercised in extending the planform to the center line. The error that could result is illustrated by the somewhat analogous cases of wings W_1, W_4, and W_7 of Reference 79 (see Table 4.1.3.2-E). These configurations are ogee wings with very slender apexes and, consequently, low values of p. It is believed that the slender apex behaves more as a body than as part of the lifting surface. For these wings the method underestimates the normal-force-curve slope from 6.5 to 21.7 percent.

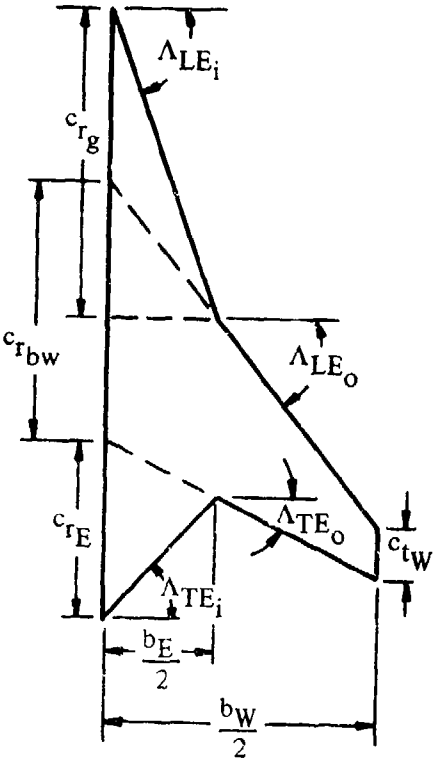
The calculated results for the configuration of Reference 81 are as much as 22 percent in error. However, the model is a sonic-design, blended wing-body configuration with unusual bumps in the wing surface near the wing-body juncture, and it is suspected that the bumps significantly affect the pressure distribution at supersonic speeds. It is significant that at subsonic speeds, test data for this configuration correlate quite well with the predicted lift at angle of attack (see results for Reference 43 in Table 4.1.3.3-D).

The authors of Reference 8 note that moderately low-aspect-ratio wings ($1.5 \leqslant A \leqslant 3.0$) have linear lift-curve slopes up to approximately eight degrees angle of attack at supersonic speeds. However, the low-aspect-ratio-wing ($A \leqslant 1.3$) data of Reference 79 show a break in the lift curve at approximately two degrees angle of attack. Unfortunately, the program reported in Reference 8 did not include an investigation of the supersonic wing-lift variation with angle of attack for irregular-shaped wings.

Sample Problems

1. Double-Delta Wing

Given: Double-delta wing of Reference 58.



Total Wing

$A_W = 2.42$ $\quad \lambda_W = 0.086$ $\quad b_W = 24.0$ in.

$\Lambda_{LE_i} = 70.67^o$ $\quad \Lambda_{LE_o} = 51.63^o$

$S_W = 238$ sq in. $\quad \eta_B = 0.40$

$\Lambda_{TE_i} = -47.37^o$ $\quad \Lambda_{TE_o} = 26.62^o$

Basic Wing

$A_{bw} = 3.50$ $\quad \lambda_{bw} = 0.20$ $\quad S_{bw} = 164.6$ sq in.

$\Lambda_{LE_{bw}} = \Lambda_{LE_o} = 51.63^o$ $\quad \Lambda_{TE_{bw}} = \Lambda_{TE_o} = 26.62^o$

Glove

$A_g = 1.402$ $\lambda_g = 0$ $\Lambda_{LE_g} = \Lambda_{LE_i} = 70.67^o$ $S_g = 65.7$ sq in.

Extension

$\frac{b_E}{2} = \eta_B \frac{b_W}{2} = 4.8$ in. $\Lambda_{TE_E} = \Lambda_{TE_i} = -47.37^o$

Additional Characteristics:

Sharp-nosed airfoil $M = 2.01; \beta = 1.744$

Compute:

$(C_{N_\alpha})_{bw}$

$\tan \Lambda_{LE_{bw}}/\beta = 0.724$; $(A \tan \Lambda_{LE})_{bw} = 4.421$

$\beta(C_{N_\alpha})_{bw} = 4.24$ per rad (Figure 4.1.3.2-56b)

$(C_{N_\alpha})_{bw} = 2.43$ per rad

$\beta/\tan \Lambda_{LE_{bw}} = 1.38$

$(C_{LE})_{bw} = 0.993$ (Figure 4.1.3.2-62)

$(C_{N_\alpha})_g$ (Since $\lambda = 0$, either Figure 4.1.3.2-56a or 4.1.3.2-63 can be used.) (See footnote on Page 4.1.3.2-23.)

$\beta/\tan \Lambda_{LE_g} = 0.612$; $(A \tan \Lambda_{LE})_g = 3.99$

$\tan \Lambda_{LE_g}(C_{N_\alpha})_g = 4.90$ per rad (Figure 4.1.3.2-56a)

$(C_{N_\alpha})_g = 1.72$ per rad

$(C_{LE})_g = 0.995$ (Figure 4.1.3.2-62)

$(C_{N_\alpha})_E \frac{S_E}{S_W}$ (use Figure 4.1.3.2-63)

$\beta/\tan \Lambda_{LE_l} = \beta/\tan \Lambda_{LE_g} = 0.612$

$$\frac{\tan \Lambda_{TE_1}}{\tan \Lambda_{LE_1}} = \frac{\tan \Lambda_{TE_E}}{\tan \Lambda_{LE_g}} = -0.381$$

$$\left(\frac{C_{N_\alpha}}{A}\right)_1 = 1.58 \text{ (Figure 4.1.3.2-63)}$$

$$\beta/\tan \Lambda_{LE_2} = \beta/\tan \Lambda_{LE_g} = 0.612$$

$$\frac{\tan \Lambda_{TE_2}}{\tan \Lambda_{LE_2}} = \frac{\tan \Lambda_{TE_{bw}}}{\tan \Lambda_{LE_g}} = 0.176$$

$$\left(\frac{C_{N_\alpha}}{A}\right)_2 = 1.07 \text{ per rad (Figure 4.1.3.2-63)}$$

$$\left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} = \left[\left(\frac{C_{N_\alpha}}{A}\right)_1 - \left(\frac{C_{N_\alpha}}{A}\right)_2\right] \frac{b_E^2}{S_W} \text{ (Equation 4.1.3.2-j)}$$

$$= (1.58 - 1.07) \frac{(9.6)^2}{238}$$

$$= 0.197 \text{ per rad}$$

$$\frac{1}{\beta}\left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} = \frac{1}{1.744}(1.72)\left(\frac{65.7}{238}\right) = 0.272$$

$K_L = 0.830$ (Figure 4.1.3.2-61)

Solution:

$$C_{N_\alpha} = K_L\left[\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} (C_{LE})_{bw} + \left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} (C_{LE})_g + \left(C_{N_\alpha}\right)_E \frac{S_E}{S_W}\right] \text{ (Equation 4.1.3.2-h)}$$

$$= 0.830\left[(2.43)\left(\frac{164.6}{238}\right)(0.993) + (1.72)\left(\frac{65.7}{238}\right)(0.995) + 0.197\right]$$

$$= 0.830\,[1.670 + 0.472 + 0.197]$$

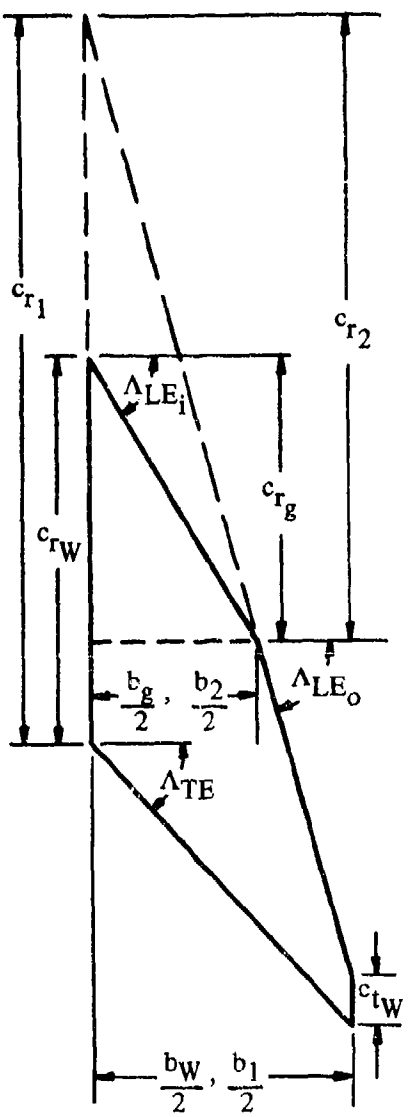
$$= 1.941 \text{ per rad}$$

$$= 0.0339 \text{ per deg}$$

This compares with a test value of 0.0351 per degree from Reference 58.

2. Double-Delta Wing $(\Lambda_{LE_o} > \Lambda_{LE_i})$

Given: The double-delta wing of Reference 75.Configuration has no trailing-edge extension.



Total Wing

$A_W = 1.86$ $\quad \lambda_W = 0.130$

$\Lambda_{LE_i} = 60^o$ $\quad \Lambda_{LE_o} = 75^o$

$S_W = 275.9$ sq in. $\quad \eta_B = 0.654$

$\Lambda_{TE} = 47.5^o$

Glove

$\frac{S_g}{S_W} = 0.346$ $\quad \lambda_g = 0$ $\quad \Lambda_{LE_g} = \Lambda_{LE_i} = 60^o$

$A_g = 2.31$

Extended Planforms

$\frac{S_1}{S_W} = 1.405$ $\quad \lambda_1 = 0.0698$

$\Lambda_{LE_1} = \Lambda_{LE_o} = 75^o$

$A_1 = 1.327$

$\frac{S_2}{S_W} = 0.745$ $\quad \lambda_2 = 0$

$\Lambda_{LE_2} = \Lambda_{LE_o} = 75^o$

$A_2 = 1.072$

Additional Characteristics

Sharp-nosed airfoil $\quad M = 3.71; \beta = 3.573$

Compute:

$(C_{N_\alpha})_g$

$\tan \Lambda_{LE_g}/\beta = 0.485$; $(A \tan \Lambda_{LE})g = 4.0$

$\beta(C_{N_\alpha})_g$ = 4.0 (Figure 4.1.3.2-56a)

$(C_{N_\alpha})_g$ = 1.12 per rad

$\beta/\tan \Lambda_{LE_g}$ = 2.06

$(C_{LE})_g$ = 1.03 (Figure 4.1.3.2-62)

$(C_{N_\alpha})_{bw} \frac{S_{bw}}{S_W}$

$(C_{N_\alpha})_1$

$\beta/\tan \Lambda_{LE_1}$ = 0.957; $(A \tan \Lambda_{LE})_1$ = 4.94

$\tan \Lambda_{LE_1} (C_{N_\alpha})_1$ = 4.40 per rad (Figures 4.1.3.2-56a through -56c, interpolated)

$(C_{N_\alpha})_1$ = 1.179 per rad

$(C_{N_\alpha})_2$

$\beta/\tan \Lambda_{LE_2}$ = 0.957; $(A \tan \Lambda_{LE})_2$ = 4.0

$\tan \Lambda_{LE_2} (C_{N_\alpha})_2$ = 4.08 (Figure 4.1.3.2-56a)

$(C_{N_\alpha})_2$ = 1.093 per rad

$$(C_{N_\alpha})_{bw} \frac{S_{bw}}{S_W} = (C_{N_\alpha})_1 \frac{S_1}{S_W} - (C_{N_\alpha})_2 \frac{S_2}{S_W}$$

$$= (1.179)(1.405) - (1.093)(0.745)$$

$$= 0.842 \text{ per rad}$$

$\beta/\tan \Lambda_{LE_{bw}}$ = 0.957

$(C_{LE})_{bw}$ = 0.94 (Figure 4.1.3.2-62)

Solution:

$$C_{N_\alpha} = K\left[\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} (C_{LE})_{bw} + \left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} (C_{LE})_g\right] \quad \text{(Equation 4.1.3.2-k)}$$

$$= 1.0\,[(0.842)(0.94) + (1.12)(0.346)(1.03)]$$

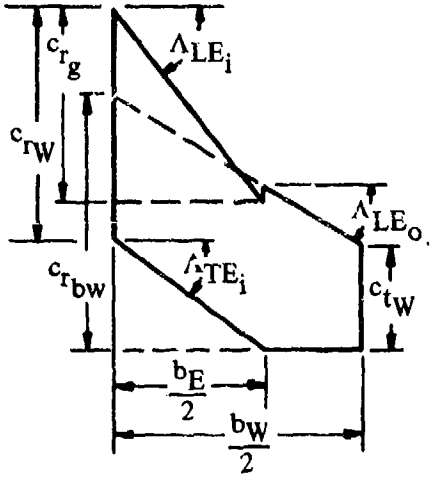
$$= 1.190 \text{ per rad}$$

$$= 0.0208 \text{ per deg}$$

This compares with a test value of 0.024 per degree from Reference 75.

3. Cranked Wing ($\Lambda_{TE_i} > \Lambda_{TE_o}$)

Given: Cranked wing of Reference 32. The inboard trailing-edge sweep angle is greater than the outboard trailing-edge sweep angle. (See Sketches (h) and (i).)



Total Wing

$A_W = 2.91$ $\quad \lambda_W = 0.44$

$\Lambda_{LE_i} = 53.13^o$ $\quad \Lambda_{LE_o} = 32.16^o$

$S_W = 40.04$ sq in. $\quad \eta_B = 0.60$

$\Lambda_{TE_i} = 37.3^o$ $\quad \Lambda_{TE_o} = 0$

Basic Wing

$A_{bw} = 2.73$ $\quad \lambda_{bw} = 0.40$ $\quad \Lambda_{LE_{bw}} = \Lambda_{LE_o} = 32.16^o$

$S_{bw} = 42.77$ sq in. $\quad b_{bw} = 10.8$ in. $\quad \Lambda_{TE_{bw}} = \Lambda_{TE_o} = 0$

Glove

$A_g = 3.0$ $\quad \Lambda_{LE_g} = \Lambda_{LE_i} = 53.13^o$ $\quad S_g = 14.00$ sq in. $\quad \lambda_g = 0$

Extension

$\frac{b_E}{2} = \eta_B \frac{b_W}{2} = 3.24$ in. $\quad \Lambda_{TE_E} = \Lambda_{TE_i} = 37.3^o$

Additional Characteristics

Round-nosed airfoil $\quad M = 1.40;\ \beta = 0.98$

Compute:

$(C_{N_\alpha})_{bw}$

$\tan \Lambda_{LE_{bw}}/\beta = 0.642$; $(A \tan \Lambda_{LE})_{bw} = 1.715$

$\beta (C_{N_\alpha})_{bw} = 3.42$ per rad (Figures 4.1.3.2-56c through -56f, interpolated)

$(C_{N_\alpha})_{bw} = 3.49$ per rad

$\beta/\tan \Lambda_{LE_{bw}} = 1.560$

$(C_{LE})_{bw} = 0.99$ (Figure 4.1.3.2-62)

$(C_{N_\alpha})_g$ (Since $\lambda = 0$, either Figure 4.1.3.2-56a or 4.1.3.2-63 can be used.)

(See footnote on Page 4.1.3.2-23.)

$\beta/\tan \Lambda_{LE_g} = 0.735$; $(A \tan \Lambda_{LE})_g = 4.0$

$\tan \Lambda_{LE_g} (C_{N_\alpha})_g = 4.575$ per rad (Figure 4.1.3.2-56a)

$(C_{N_\alpha})_g = 3.43$ per rad

$(C_{LE})_g = 0.93$ (Figure 4.1.3.2-62)

$(C_{N_\alpha})_E \frac{S_E}{S_W}$ (use Figure 4.1.3.2-63)

$\beta/\tan \Lambda_{LE_1} = \beta/\tan \Lambda_{LE_g} = 0.735$

$\frac{\tan \Lambda_{TE_1}}{\tan \Lambda_{LE_1}} = \frac{\tan \Lambda_{TE_E}}{\tan \Lambda_{LE_g}} = 0.571$

$\left(\frac{C_{N_\alpha}}{A}\right)_1 = 0.650$ per rad (Figure 4.1.3.2-63)

$\beta/\tan \Lambda_{LE_2} = \beta/\tan \Lambda_{LE_g} = 0.735$

$\frac{\tan \Lambda_{TE_2}}{\tan \Lambda_{LE_2}} = \frac{\tan \Lambda_{TE_{bw}}}{\tan \Lambda_{LE_g}} = 0$

$\left(\frac{C_{N_\alpha}}{A}\right)_2 = 1.16$ per rad (Figure 4.1.3.2-63)

$$\left(C_{N_\alpha}\right)_E \frac{S_E}{S_W} = \left[\left(\frac{C_{N_\alpha}}{A}\right)_1 - \left(\frac{C_{N_\alpha}}{A}\right)_2\right] \frac{b_E^2}{S_W} \quad \text{(Equation 4.1.3.2-j)}$$

$$= (0.650 - 1.16) \frac{(6.48)^2}{40.04}$$

$$= -0.535 \text{ per rad}$$

$$\frac{1}{\beta}\left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} = \frac{1}{0.98} (3.43) \frac{(14.00)}{(40.04)} = 1.224$$

K_L = 0.74 (Figure 4.1.3.2-61)

Solution:

$$C_{N_\alpha} = K_L\left[\left(C_{N_\alpha}\right)_{bw} \frac{S_{bw}}{S_W} (C_{LE})_{bw} + \left(C_{N_\alpha}\right)_g \frac{S_g}{S_W} (C_{LE})_g + \left(C_{N_\alpha}\right)_E \frac{S_E}{S_W}\right] \quad \text{(Equation 4.1.3.2-h)}$$

$$= 0.74\left[(3.49) \frac{(42.77)}{(40.04)} (0.99) + (3.43) \frac{(14.00)}{(40.04)} (0.93) - 0.535\right]$$

$$= 0.74\ [3.691 + 1.115 - 0.535]$$

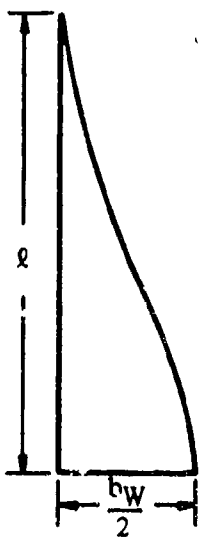
$$= 3.160 \text{ per rad}$$

$$= 0.0552 \text{ per deg}$$

This compares with a test value of 0.0563 per degree from Reference 32.

4. Curved Wing

Given: Ogee wing of Reference 80.



A_W = 1.20 b_W = 12.0 in. ℓ = 20.0 in. S_W = 120 sq in.

M = 1.82; β = 1.52

Compute:

Planform shape parameter

$$p = S_W/(b_W \ell) = (120)/[(12)(20)] = 0.50$$

Wing slenderness parameter

$$b_W/(2\ell) = (12.0)/[(2)(20)] = 0.30$$

$$\frac{\beta b_W}{2\ell} = \frac{(1.52)(12.0)}{(2)(20.0)} = 0.456$$

$$\left(\frac{C_{N_\alpha}}{A}\right)\left(\frac{1+p}{p}\right) = 4.18 \text{ per rad (Figure 4.1.3.2-64)}$$

Solution:

$$C_{N_\alpha} = \left(\frac{C_{N_\alpha}}{A}\right)\left(\frac{1+p}{p}\right) A \left(\frac{p}{1+p}\right) \text{ (Equation 4.1.3.2-}\ell\text{)}$$

$$= (4.18)(1.20)\left(\frac{0.50}{1+0.50}\right)$$

$$= 1.672 \text{ per rad}$$

$$= 0.0292 \text{ per deg}$$

This compares with a test value of 0.0285 per degree from Reference 80.

D. HYPERSONIC

The theoretical normal-force-curve slope of a flat plate at zero angle of attack approaches zero as the Mach number becomes large. The interrelated effects of viscosity, heat transfer, and detached shock waves due to blunt leading edges cause considerable deviations of the normal-force-curve slope from the theoretical values. These effects are discussed more fully in Paragraph D of Section 4.1.3.3. The magnitude of these effects on surface pressures, although large enough to be important under certain conditions, has not been determined. The method presented herein is based on linear theory and is intended only as a first-order approximation of the normal-force-curve slope of straight-tapered planforms at hypersonic speeds.

DATCOM METHOD

The hypersonic portions of Figures 4.1.3.2-56a through 4.1.3.2-56g may be used to obtain a first-order approximation of the normal-force-curve slope at zero angle of attack for conventional wings of zero thickness. For planforms with wedge airfoils an approximation of the normal-force-curve slope at zero angle of attack may be obtained by applying the results of Figure 4.1.3.2-65. This figure, based on two-dimensional supersonic slender-airfoil theory, presents the ratio of C_{N_α} of wedge airfoils to C_{N_α} of flat-plate airfoils.

(a) These models had theoretically round L.E.'s inboard but were analyzed as sharp due to small size of model and small t/c.

(b) This model had a flat plate wing with a blunt T.E.

$$\text{Average Error} = \frac{\Sigma \mid e \mid}{n} = 3.7\%$$

SKETCH (a)

The aspect-ratio-6 wing with the 64A010 airfoil reaches a maximum lift coefficient at a relatively low angle of attack. Following this, the lift drops abruptly and then stabilizes at nearly constant level for approximately the next 30° of angle of attack.

For the same wing with a sharp leading edge (represented by the wing in reverse flow) the maximum lift coefficient is not nearly as large as in the previous case, but the drop subsequent to the maximum lift is also much less. The result is that for angles of attack beyond stall, the lift on the blunt wing is not greatly different from the lift on the sharp wing.

This effect is accounted for in this section by making the drop in lift following maximum lift reflect the difference between the actual maximum lift and the maximum lift determined by the low-aspect-ratio method of Section 4.1.3.4. (This latter method gives results corresponding to those for a thin airfoil.)

For very low-aspect-ratio rectangular wings experimental data (reference 2) occasionally show a hysteresis in the normal-force curve near maximum lift, with different lift-curve shapes, depending on whether the angle of attack is increasing or decreasing. For these wings the results of this section must be applied with caution, since they do not reflect this hysteresis.

Reynolds number was not accounted for in the analysis of this method. There is a Reynolds-number effect on the lift-curve shape for the thicker wings, but within the Reynolds-number limitations listed on the charts the values predicted are of sufficient accuracy for most purposes.

DATCOM METHOD

The general method for estimating the subsonic normal force on conventional, straight-tapered uncambered wings for angles of attack from 0 to 90° is outlined in the following steps:

Step 1. Subsonic Normal Force at Angles of Attack Below the Stall.

The basic equation is

$$\frac{C_L}{\cos \alpha} = C_N' = C_{N_\alpha} \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin \alpha \, | \sin \alpha | \qquad 4.1.3.3\text{-a}$$

The normal-force-curve slope C_{N_α} is obtained from Section 4.1.3.2.* For high-aspect-ratio

*C_{L_α} is used for C_{N_α}

wings, the lift curve is based on the appropriate section lift-curve slope. For low-aspect ratios and borderline aspect ratios (defined in Section 4.1.3.4), the section lift-curve slope is assumed to be 2π ($\kappa = 1$ in figure 4.1.3.2-49).

The nonlinear coefficient $C_{N_{aa}}$ is calculated as the sum of two terms:

$$C_{N_{aa}} = \left(C_{N_{aa}}\right)_{ref} + \Delta C_{N_{aa}} \qquad 4.1.3.3\text{-b}$$

The reference nonlinear coefficient $\left(C_{N_{aa}}\right)_{ref}$ is based on C'_N at $C_{L_{max}}$ (the normal force at maximum lift), given by

$$C'_N \ @ \ C_{L_{max}} = \frac{C_{L_{max}}}{\cos a_{C_{L_{max}}}} \qquad 4.1.3.3\text{-c}$$

where $C_{L_{max}}$ and $a_{C_{L_{max}}}$ are obtained as outlined in Section 4.1.3.4 for the wing in question. Finally, $\left(C_{N_{aa}}\right)_{ref}$ is given by

$$\left(C_{N_{aa}}\right)_{ref} = \frac{C'_N \ @ \ C_{L_{max}} - C_{N_a}\left(\frac{1}{2}\right)\sin 2a_{C_{L_{max}}}}{\sin a_{C_{L_{max}}}\left|\sin a_{C_{L_{max}}}\right|} \qquad 4.1.3.3\text{-d}$$

The incremental nonlinear lift coefficient $\Delta C_{N_{aa}}$ is now read from figure 4.1.3.3-55a as a function of the parameter J and the ratio of the tangent of the angle of attack in question to the tangent of the angle of attack at $C_{L_{max}}$. The wing-shape parameter J is defined by the equation

$$J = 0.3\ (C_1 + 1)\frac{A}{\beta}\cos \Lambda_{LE}\left\{(C_1 + 1)\ (C_2 + 1) - \left[\frac{(C_2 + 1)\,A \tan \Lambda_{LE}}{7}\right]^3\right\} \qquad 4.1.3.3\text{-e}$$

The constants C_1 and C_2 are the empirical taper-ratio constants of Section 4.1.3.4.

The wing lift coefficient may now be calculated for any angle of attack up to and including the stall by substituting the appropriate values of C_{N_a} and $C_{N_{aa}}$ in equation 4.1.3.3-a.

Step 2. Subsonic Normal Force at Angles of Attack Beyond the Stall.

The equation for the nonlinear coefficient at angles of attack beyond the stall is

$$C_{N_{aa}} = \left(C_{N_{aa}}\right)_{ref} + \left[\left(C_{N_{aa}}\right)_{90^\circ} - \left(C_{N_{aa}}\right)_{ref}\right]\left[1 - \frac{\tan a_{C_{L_{max}}}}{\tan a}\right] + \beta^2 D \frac{C_{N_a}}{2.3}\left(\frac{C_{L_{max}}}{C^*_{L_{max}}}\right)^2 \qquad 4.1.3.3\text{-f}$$

where

$\left(C_{N_{aa}}\right)_{ref}$ is the reference nonlinear coefficient based on C_N' at $C_{L_{max}}$, calculated as outlined in step 1.

$\left(C_{N_{aa}}\right)_{90^o}$ is the normal-force coefficient at $\alpha = 90^o$. At 90^o, $C_{N_{aa}} = C_N'$ since $\sin^2 \alpha = 1$ and $\frac{\sin 2\alpha}{2} = 0$. The quantity C_N' is obtained from figure 4.1.3.3-55b as a function of aspect ratio (references 3 and 4).

β is the Mach number parameter, $\sqrt{1 - M^2}$.

D is an empirical nonlinear term read from the right-hand side of figure 4.1.3.3-55a.

$C_{L_{max}}$ is the maximum lift coefficient obtained as outlined in Section 4.1.3.4 for the wing in question.

$C^*_{L_{max}}$ is the maximum lift coefficient of the wing, calculated by using the low-aspect-ratio method of paragraph B of Section 4.1.3.4. If the wing in question has a low aspect ratio by the definition of Section 4.1.3.4, then $C^*_{L_{max}} = C_{L_{max}}$ and the last term in equation 4.1.3.3-f is $\beta D^2 \frac{C_{N_\alpha}}{2.3}$. If the wing in question has a high aspect ratio by the definition of Section 4.1.3.4, the value of $\left(C_{L_{max}}\right)_{base}$ is obtained from figure 4.1.3.4-23 at $(C_1 + 1)\frac{A}{\beta}\cos \Lambda_{LE} = \frac{4}{\beta}$.

Substituting values of $C_{N_{aa}}$ determined by equation 4.1.3.3-f, together with the value of C_{N_α} from figure 4.1.3.2-49$_b$ into equation 4.1.3.3-a gives the wing normal-force coefficient for angles of attack between the stall angle and 90^o.

For cambered wings the procedure outlined in steps 1 and 2 must be altered slightly. Potential theory states that the lift-curve slope of a wing is unaltered by camber. Thus the lift is defined by

$$C_L = C_{L_\alpha}(\alpha - \alpha_0)$$

where α_0 is the angle of attack for zero lift. For angles of attack below the stall an equivalent angle of attack for the cambered wing is defined as $\alpha_e = \alpha - \alpha_0$. Then, the equations for lift are

$$C_L = C_N' \cos \alpha$$

$$C_N' = C_{N_\alpha}\frac{\sin 2\alpha_e}{2} + C_{N_{aa}} \sin \alpha_e |\sin \alpha_e| \quad \text{(equation 4.1.3.3-a)}$$

where $C_{N_{aa}}$ is given by equation 4.1.3.3-b, but with $\alpha_{C_{L_{max}}}$ replaced by $(\alpha_e)_{C_{L_{max}}}$ in determining

$\left(C_{N_{aa}}\right)_{ref}$ and $\Delta C_{N_{aa}}$; i.e.,

$$\left(C_{N_{aa}}\right)_{ref} = \frac{C'_N \text{ @ } C_{L_{max}} - C_{N_a}\left(\frac{1}{2}\right)\sin 2(a_e)_{C_{L_{max}}}}{\sin (a_e)_{C_{L_{max}}} \left|\sin (a_e)_{C_{L_{max}}}\right|} \quad \text{(equation 4.1.3.3-d)}$$

$\Delta C_{N_{aa}}$ is read from figure 4.1.3.3-55a as a function of J and the ratio $\frac{\tan a_e}{\tan (a_e)_{C_{L_{max}}}}$.

For angles of attack beyond the stall, the linear term vanishes as a approaches 90^o, and the equivalent angle of attack for the cambered wing is defined as

$$a_e = a\left[1 + \frac{a_0}{90^o - a_{C_{L_{max}}}}\right] - \frac{90^o\, a_0}{90^o - a_{C_{L_{max}}}} \qquad 4.1.3.3\text{-g}$$

where a, a_0, and $a_{C_{L_{max}}}$ are measured in degrees. Then, as before,

$$C_L = C'_N \cos a$$

$$C'_N = C_{N_a}\frac{\sin 2a_e}{2} + C_{N_{aa}} \sin a_e \left|\sin a_e\right| \quad \text{(equation 4.1.3.3-a)}$$

where $C_{N_{aa}}$ is given by equation 4.1.3.3-f with $\left(C_{N_{aa}}\right)_{ref}$ calculated as outlined above for the cambered wing at angles of attack below the stall, and $a^* = a_e$.

In applying the above methods to a wing which is on the borderline between a high aspect ratio and a low aspect ratio as defined in Section 4.1.3.4, i.e., $\frac{3}{(C_1 + 1)\cos \Lambda_{LE}} \leqslant A \leqslant \frac{4}{(C_1 + 1)\cos \Lambda_{LE}}$, either the high- or the low-aspect-ratio procedure of Section 4.1.3.4 may be applied to determine the wing maximum-lift characteristics. It is suggested that the low-aspect-ratio procedure be applied as this facilitates application of equation 4.1.3.3-f, since $C^*_{L_{max}} = C_{L_{max}}$.

Three sample problems are included on pages 4.1.3.3-11 through 4.1.3.3-23 to illustrate the calculation procedure for estimating wing lift in the nonlinear angle-of-attack range of conventional, straight-tapered wings. Comparison with experimental data is presented in each case.

Sample problems 1 and 2 emphasize the high-angle-of-attack characteristics of a low-aspect-ratio and a high-aspect-ratio wing, respectively. Comparison is made between the calculated and experimental values for both lift and normal force. Agreement between the calculated and experimental values near stall is not particularly good for the high-aspect-ratio wing. However, the experimental data in this case should be viewed with caution, since it indicates a highly nonlinear lift curve prior to stall for a high-aspect-ratio wing.

Sample problem 3 illustrates the special case of a cambered wing, as well as a more representative comparison of lift at the lower angles of attack.

Non-Straight-Tapered Wings

Semiempirical methods, taken from reference 1, are presented for estimating the nonlinear lift of double-delta and cranked wings at subsonic speeds. The nonlinear lift of double-delta wings is based on the hypothesis that an expression similar to that developed by Küchemann (reference 8) for the nonlinear lift of small-aspect-ratio wings with leading-edge separation may be applied to double-delta planforms. By using such an approach, a correlation proportional to the linear lift-curve slope was developed that is strongly dependent on the inboard-panel geometry. The characteristic behavior exhibited by the experimental data of cranked wings led the authors of reference 1 to conclude that the flow field about these wings is similar to that about a low-aspect-ratio delta wing with leading-edge separation. On the basis of these observations, the nonlinear lift of cranked wings has been related to the correlation for the nonlinear lift of double-delta wings.

The nonlinear lift of curved (Gothic and ogee) wings has been correlated in reference 1 by the empirical method developed by Peckham in reference 9.

The following methods for estimating the nonlinear lift of non-straight-tapered wings are limited to angles of attack of 20° or less.

DATCOM METHODS

Double-Delta Wings

The nonlinear lift of double-delta wings at subsonic speeds is obtained from the procedure outlined in the following steps:

Step 1. Calculate the subsonic wing lift-curve slope C_{L_α} by the method presented for double-delta wings in paragraph A of Section 4.1.3.2.

Step 2. Obtain values of the parameter $\frac{C_L}{C_{L_\alpha}} \frac{A_i}{\eta_B}$ at angles of attack of 4°, 8°, 12°, 16°, and 20° from figure 4.1.3.3-56. This parameter is correlated as a function of wing aspect ratio A, the leading-edge sweepback of the inboard panel Λ_{LE_i}, and the Mach number parameter $\beta = \sqrt{1 - M^2}$. It should be noted that for angles of attack up to 8°, an aspect-ratio dependence exists at Mach numbers above 0.7. Not enough data are available at high subsonic Mach numbers to allow investigation of the aspect-ratio dependence above 8° angle of attack.

Step 3. Calculate C_L by

$$C_L = \left(\frac{C_L}{C_{L_\alpha}} \frac{A_i}{\eta_B}\right) \frac{C_{L_\alpha}}{A_i/\eta_B} \qquad 4.1.3.3\text{-h}$$

where

η_B is the spanwise location of the break in the leading edge expressed in percent of wing semispan.

A_i is the aspect ratio of the planform formed by the two inboard panels

Step 4. Plot calculated values of C_L versus α and fair a curve through the points tangent to C_{L_α} near zero lift.

Application of this technique is illustrated by sample problem 4 at the conclusion of paragraph A (page 4.1.3.3-23).

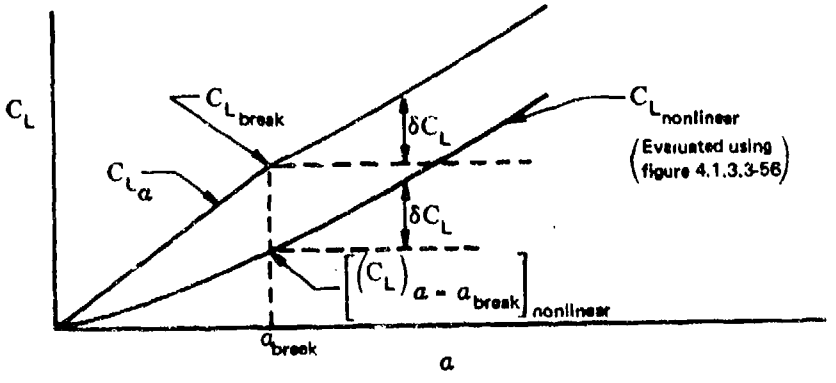
A comparison of test data for 21 configurations with the nonlinear lift of double-delta wings calculated by this method is presented as table 4.1.3.3-B (taken from reference 1). The largest errors generally occur at $\alpha = 4^{\circ}$ with the accuracy improving as the angle of attack increases. The ratio of body diameter to wing span of the models investigated varied from 0.077 to 0.149, and no apparent effects of relative body size are evident. No significant effects of thickness ratio on lift are evident over the limited thickness-ratio range covered (0.02 to 0.04). The Reynolds numbers of the test data fall into two ranges, 1.04×10^6 to 3.6×10^6 and 17.1×10^6 to 20.3×10^6. Although there are not enough data to allow a quantitative prediction of Reynolds-number effect, it is reasonable to expect that Reynolds number will influence the lift.

Although no attempt was made to define the effect of leading-edge shape on lift, even with round leading edges a highly-swept wing should be expected to have leading-edge separation at the higher angles of attack. With separated flow over the entire leading edge, the resulting vortex pattern should be equivalent to that for a wing with a sharp leading edge. Since the vortex pattern exerts a strong influence on the flow field, at the higher angles of attack the aerodynamic characteristics of wings with round and sharp leading edges should be similar.

It is difficult to assess quantitatively the validity of the aspect-ratio dependence, shown in figure 4.1.3.3-56, at Mach numbers above 0.7. This dependence is based on only nine configurations, and no data are available above 8° angle of attack.

Cranked Wings

The nonlinear lift of cranked wings at subsonic speeds is related to the correlation for the nonlinear lift of double-delta wings presented as figure 4.1.3.3-56. The prediction method consists of a construction procedure for the buildup of lift above the angle of attack at which the lift curve breaks. The break in the lift curve is defined as that point where the lift drops off from the linear value, and the curve itself also becomes nonlinear. The cranked wings examined during the analysis reported in reference 1 showed a break in the lift curve at angles of attack between 6° and 7°. The prediction method is illustrated schematically in sketch (b).



SKETCH (b)

By referring to sketch (b), the nonlinear lift of cranked wings at subsonic speeds is obtained from the procedure outlined in the following steps:

Step 1. Calculate the subsonic wing lift-curve slope C_{L_α} by the method presented for cranked wings in paragraph A of Section 4.1.3.2.

Step 2. Obtain α_{break} as a function of the leading-edge sweepback of the inboard panel from figure 4.1.3.3-57.

Step 3. Calculate $C_{L_{break}}$ by

$$C_{L_{break}} = C_{L_\alpha} \alpha_{break} \qquad 4.1.3.3\text{-i}$$

Step 4. Obtain values of the parameter $\frac{C_L}{C_{L_\alpha}} \frac{A_I}{\eta_B}$ at angles of attack of 4^o, 8^o, 12^o, 16^o, and 20^o from figure 4.1.3.3-56, and calculate $C_{L_{nonlinear}}$ using equation 4.1.3.3-h. (See double-delta-wing method of this paragraph.)

Step 5. Obtain $\left[(C_L)_{\alpha=\alpha_{break}}\right]_{nonlinear}$ by plotting $C_{L_{nonlinear}}$ versus α from step 4, and then calculate δC_L by

$$\delta C_L = \left[C_L - (C_L)_{\alpha=\alpha_{break}}\right]_{nonlinear} \qquad 4.1.3.3\text{-j}$$

Step 6. Add the δC_L values obtained in step 5 to the $C_{L_{break}}$ value obtained in step 3 to obtain the total C_L for each α above α_{break}; i.e.,

$$C_L = C_{L_{break}} + \delta C_L \qquad 4.1.3.3\text{-k}$$

Application of this technique is illustrated by sample problem 5 on page 4.1.3.3-25.

A comparison of test data for seven configurations with the nonlinear lift of cranked wings calculated by this method is presented as table 4.1.3.3-C (taken from reference 1). The ratio of body diameter to wing span of the models investigated varied from 0.062 to 0.147, and no apparent effects of relative body size are evident. No significant effects of thickness ratio on lift are evident over the limited thickness-ratio range covered (0.02 to 0.06).

Before attempting to assess the validity of the method some salient features should be pointed out. The accuracy of the method is strongly dependent on knowing α_{break}. Since the break in the lift curve is essentialy a type of stall phenomenon, Reynolds number may have a significant effect on α_{break}. Unfortunately, a lack of data prevented a detailed study of Reynolds number effects during the correlation reported in reference 1. The method also assumes a sharp discontinuity at α_{break}; however, test data show that as aspect ratio is reduced the break in the lift curve becomes less apparent, and for the lower-aspect-ratio wings the lift curve exhibits a gradual transition from the linear to the nonlinear region. Furthermore, the shape of the nonlinear lift curve is based on the correlation derived for double-delta wings, which is restricted to wings with small or zero trailing-edge sweep angles.

From the foregoing discussion it might be expected that the method would give acceptable results when applied to wings with moderate to high aspect ratios and small or zero trailing-edge sweep angles. Of the seven configurations listed in table 4.1.3.3-C, these conditions are met only by the configurations of references 37, 38, and 39. The average error for the nine calculated points of those references is 4.9 percent.

It is difficult to assess quantitatively the effect of Mach number on the accuracy of the method. However, it should be pointed out that the curves of figure 4.1.3.3-56 have been extrapolated to account for low values

of $\beta \tan \Lambda_{LE_i}$ for the configuration of reference 28 at M = 0.80, 0.85, and 0.90 and for the configurations of reference 36 at M = 0.90.

Since the configurations of references 38 and 39 had twisted and cambered wings, their lift curves were significantly displaced from the origin. In analyzing the test data for these configurations the lift curves were shifted so that $C_{L_{\alpha=0}} = 0$. The calculated results for these configurations compared well with the adjusted test values, indicating that twist and camber have a negligible effect on the shape of the lift curve in the nonlinear region.

Test data show that the lift curve tends to fall off at approximately 16° angle of attack at M = 0.80 and 0.85 for the configuration of reference 28, and at approximately 12° angle of attack throughout the Mach range tested for both configurations of reference 36. This trend indicates that the inboard panel is beginning to stall; consequently, the method should not be expected to give reliable results for these configurations at higher angles of attack.

Curved Wings

The nonlinear lift of curved (Gothic and ogee) wings at subsonic speeds was correlated in reference 1 by Peckham's method (reference 9) where the ratio of lift to the square root of the wing slenderness parameter plotted versus angle of attack converges on a single curve.

The nonlinear lift is obtained from the procedure outlined in the following steps:

Step 1. Using the given wing geometry calculate the wing slenderness parameter $\frac{b_W}{2\ell}$. (See Section 2.2.2 for wing-geometry parameters.)

Step 2. At the desired values of angle of attack obtain $C_L\sqrt{\frac{b_W}{2\ell}}$ from figure 4.1.3.3-58.

Step 3. Calculate C_L at each α by

$$C_L = \frac{C_L}{\sqrt{\frac{b_W}{2\ell}}} \sqrt{\frac{b_W}{2\ell}} \qquad 4.1.3.3\text{-}\ell$$

Application of this technique is illustrated by the sample problem on page 4.1.3.3-28.

A comparison of test data for 11 configurations with the nonlinear lift of curved wings calculated by this method is presented as table 4.1.3.3-D (taken from reference 1). The results indicate that the best accuracy is obtained at the lower Mach numbers and for configurations with aspect ratios near 1.0. Three of the configurations analyzed were wing-bodies, and for these configurations no significant wing-body interference effects were evident. However, it should be noted that no blended wing-body configurations are included in the correlation. Such configurations have a very thick cross section near the apex that should be expected to cause a loss in lift. The two blended wing-body configurations of references 43 and 44 were analyzed during the investigation reported in reference 1, and it was found that the lift predicted using figure 4.1.3.3-58 was about 10 percent higher than test data throughout the angle-of-attack range of both configurations.

Since there is no theoretical basis for this method, it should be used with caution outside the planform parameter ranges covered in the correlation. The correlation of figure 4.1.3.3-58 is based on data from sharp-edged, thin, Gothic and ogee wings with moderate trailing-edge sweep angles (±15°). The planform param-

eter ranges of the data are

$$0.75 \leqslant A \leqslant 2.00$$

$$0.45 \leqslant \frac{S_W}{b_W \ell} \leqslant 0.667$$

$$0.25 \leqslant \frac{b_W}{2\ell} \leqslant 0.54$$

Sample Problems

Conventional, Straight-Tapered Wings

1. High-Angle-of-Attack Characteristics of a Low-Aspect-Ratio Wing.

Given: Delta wing of reference 25.

$A = 2.0$ $\lambda = 0$ $\Lambda_{LE} = 63.5^{o}$ NACA 0005 airfoil (free-stream direction)

$M = 0.2$; $\beta = 0.98$ $R_\ell = 1.2$ to 2.2×10^6 (based on MAC)

$\kappa = 1.0$ (assumed) $\Lambda_{c/2} = 45.2^{o}$

Compute: Angles of attack below the stall

Find $C_{L_{max}}$ and $\alpha_{C_{L_{max}}}$ as outlined in Section 4.1.3.4 and C_{N_α} from Section 4.1.3.2.

$A < \dfrac{3}{(C_1 + 1)\cos \Lambda_{LE}}$; therefore, use low-aspect-ratio method.

$\Delta y = 1.38$ (figure 2.2.1-8)

$C_1 = 0$, $C_2 = 0$ (figure 4.1.3.4-24b)

$(C_1 + 1)\dfrac{A}{\beta}\cos \Lambda_{LE} = \dfrac{2}{0.98}(0.4462) = 0.91$

$\left(C_{L_{max}}\right)_{base} = 1.29$ (figure 4.1.3.4-23a)

$(C_2 + 1)\ A \tan \Lambda_{LE} = 2(2.006) = 4.01$

$\Delta C_{L_{max}} = 0$ (figure 4.1.3.4-24a)

$C_{L_{max}} = \left(C_{L_{max}}\right)_{base} + \Delta C_{L_{max}}$ (equation 4.1.3.4-g)

$= 1.29$

$$\left(a_{C_{L_{max}}}\right)_{base} = 34.6^{o} \text{ (figure 4.1.3.4-25a)}$$

$$A \cos \Lambda_{LE} \left[1 + (2\lambda)^2\right] = 2\,(0.4462)\,[1 + 0] = 0.8924$$

$$\Delta a_{C_{L_{max}}} = -0.1^{o} \text{ (figure 4.1.3.4-25b)}$$

$$a_{C_{L_{max}}} = \left(a_{C_{L_{max}}}\right)_{base} + \Delta a_{C_{L_{max}}} \quad \text{(equation 4.1.3.4-h)}$$

$$= 34.5^{o}$$

Find C_{L_a}

$$\frac{A}{\kappa}\left[\beta^2 + \tan^2 \Lambda_{c/2}\right]^{\frac{1}{2}} = 2.81$$

$$C_{L_a}/A = 1.15 \text{ per rad (figure 4.1.3.2-49)}$$

$$C_{L_a} = C_{N_a} = \left(\frac{C_{L_a}}{A}\right) A = (1.15)\,(2.0) = 2.30 \text{ per rad}$$

Find $\left(C_{N_{aa}}\right)_{ref}$

$$C'_N \;@\; C_{L_{max}} = \frac{C_{L_{max}}}{\cos a_{C_{L_{max}}}} \quad \text{(equation 4.1.3.3-c)}$$

$$= \frac{1.29}{0.8241} = 1.565$$

$$\left(C_{N_{aa}}\right)_{ref} = \frac{C'_N \;@\; C_{L_{max}} - C_{N_a}\left(\frac{1}{2}\right)\sin 2a_{C_{L_{max}}}}{\sin a_{C_{L_{max}}}\left|\sin a_{C_{L_{max}}}\right|} \quad \text{(equation 4.1.3.3-d)}$$

$$\frac{1.565 - 2.30\left(\frac{0.9336}{2}\right)}{(0.5664)^2} = 1.53$$

Find J

$$J = 0.3\,(C_1 + 1)\frac{A}{\beta}\cos \Lambda_{LE}\left\{(C_1 + 1)\,(C_2 + 1) - \left[\frac{(C_2 + 1)\,A \tan \Lambda_{LE}}{7}\right]^3\right\}$$

(equation 4.1.3.3-e)

$$= 0.3\,(1)\left(\frac{2}{0.98}\right)(0.4462)\left\{1 - \left[\frac{2\,(2.006)}{7}\right]^3\right\}$$

$$= 0.222$$

Solution: Angles of Attack Below the Stall

$$\frac{C_L}{\cos\alpha} = C_N' = C_{N_\alpha}\frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}}\sin\alpha\,|\sin\alpha| \quad \text{(equation 4.1.3.3-a)}$$

$$C_{N_{\alpha\alpha}} = \left(C_{N_{\alpha\alpha}}\right)_{\text{ref}} + \Delta C_{N_{\alpha\alpha}} \quad \text{(equation 4.1.3.3-b)}$$

SKETCH (c)

2. High-Angle-of-Attack Characteristics of a High-Aspect-Ratio Wing.

Given: Wing 7 of reference 25.

$A = 6.0 \quad \lambda = 0.5 \quad \Lambda_{LE} = 8.9^{\circ}$ NACA 64A010 airfoil (free-stream direction)

$M = 0.2; \quad \beta = 0.98 \quad R_{\ell} = 1.5$ to 2.2×10^6 (based on MAC)

$\kappa = 1.0$ (assumed) $\quad \Lambda_{c/2} = 2.6^{\circ}$

Compute: Angles of Attack Below the Stall

Find $C_{L_{max}}$ and $\alpha_{C_{L_{max}}}$ as outlined in Section 4.1.3.4 and C_{N_α} from Section 4.1.3.2.

$A > \dfrac{4}{(C_1 + 1) \cos \Lambda_{LE}}$; therefore, use high-aspect-ratio method

$\Delta y = 2.10$ (figure 2.2.1-8)

$c_{\ell_{max}} = 1.23$ at $R_{\ell} = 9 \times 10^6$ (table 4.1.1-B)

$\Delta_3 c_{\ell_{max}} = -0.14$ for $R_{\ell} = 2.0 \times 10^6$ (figure 4.1.1.4-7b, extrapolated)

$c_{\ell_{max}} = 1.23 - 0.14 = 1.09$ (adjusted for test R_{ℓ})

$\dfrac{C_{L_{max}}}{c_{\ell_{max}}} = 0.895$ (figure 4.1.3.4-21a)

$\Delta C_{L_{max}} = 0$ (figure 4.1.3.4-22)

$$C_{L_{max}} = \left(\frac{C_{L_{max}}}{c_{\ell_{max}}} \right) c_{\ell_{max}} + \Delta C_{L_{max}} \quad \text{(equation 4.1.3.4-d)}$$

$$= (0.895)(1.09) = 0.975$$

Find C_{L_α}

$$\frac{A}{\kappa} \left[\beta^2 + \tan^2 \Lambda_{c/2} \right]^{1/2} = 5.89$$

$C_{L_\alpha}/A = 0.76$ per rad (figure 4.1.3.2-49)

$$C_{L_\alpha} = C_{N_\alpha} = \left(\frac{C_{L_\alpha}}{A}\right) A = (0.76)(6) = 4.56 \text{ per rad}$$

$$\Delta\alpha_{C_{L_{max}}} = 1.0^{O} \text{ (figure 4.1.3.4-21b)}$$

$$\alpha_0 = \alpha_i - \frac{c_{\ell_i}}{c_{\ell_\alpha}} = 0 - \frac{0}{0.110} = 0 \text{ (equation 4.1.3.1-a)}$$

$$\alpha_{C_{L_{max}}} = \frac{C_{L_{max}}}{C_{L_\alpha}} + \alpha_0 + \Delta\alpha_{C_{L_{max}}} \text{ (equation 4.1.3.4-e)}$$

$$= \frac{0.975}{4.56/(57.3)} + 0 + 1.0 = 13.3^{O}$$

Find $\left(C_{N_{\alpha\alpha}}\right)_{ref}$

$$C'_N \text{ @ } C_{L_{max}} = \frac{C_{L_{max}}}{\cos \alpha_{C_{L_{max}}}} = \frac{0.975}{0.9732} = 1.002 \text{ (equation 4.1.3.3-c)}$$

$$\left(C_{N_{\alpha\alpha}}\right)_{ref} = \frac{C'_N \text{ @ } C^{*}_{L_{max}} - C_{N_\alpha}\left(\frac{1}{2}\right)\sin 2\alpha_{C_{L_{max}}}}{\sin \alpha_{C_{L_{max}}} \left|\sin \alpha_{C_{L_{max}}}\right|} \text{ (equation 4.1.3.3-d)}$$

$$= \frac{1.002 - 4.56\ \frac{0.4478}{2}}{(0.2300)^2} = -0.359$$

Find J

$C_1 = 0.3$, $C_2 = 1.06$ (figure 4.1.3.4-24b)

$$J = 0.3\,(C_1 + 1)\,\frac{A}{\beta}\cos\Lambda_{LE}\left\{(C_1 + 1)(C_2 + 1) - \left[\frac{(C_2 + 1)\,A\tan\Lambda}{7}\right]^3\right\}$$

(equation 4.1.3.3-e)

$$= 0.3\,(1.31)\,\frac{6}{0.98}\,(0.988)\left\{(1.31)(2.06) - \left[\frac{(2.06)(6)(0.1566)}{7}\right]^3\right\}$$

$$= 6.36$$

Solution: Angles of Attack Below the Stall

$$\frac{C_L}{\cos a} = C'_N = C_{N_a} \frac{\sin 2a}{2} + C_{N_{aa}} \sin a \,|\sin a| \quad \text{(equation 4.1.3.3-a)}$$

$$C_{N_{aa}} = \left(C_{N_{aa}}\right)_{ref} + \Delta C_{N_{aa}} \quad \text{(equation 4.1.3.3-b)}$$

SKETCH (d)

3. Angle-of-Attack Characteristics of a Cambered Wing

Given: The wing of reference 26.

$A = 9.0$ $\lambda = 0.4$ $\Lambda_{LE} = 2.2^{o}$ NACA 63_1 –210 airfoil (free-stream direction)

Position of maximum t/c = 0.45c
Position of maximum camber = 0.50c
Amount of camber = 0.011c

$M = 0.30$; $\beta = 0.954$ $R_\ell = 2.5 \times 10^6$ (based on MAC)

$\kappa = 1.0$ (assumed) $\Lambda_{c/2} = 3.25^{o}$

Compute: Angles of Attack Below the Stall

Find $C_{L_{max}}$ and $\alpha_{C_{L_{max}}}$ as outlined in Section 4.1.3.4 and C_{N_α} from Section 4.1.3.2.

$A > \dfrac{4}{(C_1 + 1)\cos\Lambda_{LE}}$; therefore, use high-aspect-ratio method

$\Delta y = 2.20$ (figure 2.2.1-8)

$\left(c_{\ell_{max}}\right)_{base} = 1.28$ (uncambered wing at $R_\ell = 9 \times 10^6$) (figure 4.1.1.4-5)

$\Delta_1 c_{\ell_{max}} = 0.07$ (figure 4.1.1.4-6d)

$\Delta_2 c_{\ell_{max}} = 0.15$ (figure 4.1.1.4-7a)

$\Delta_3 c_{\ell_{max}} = -0.13$ (figure 4.1.1.4-7b)

$c_{\ell_{max}} = \left(c_{\ell_{max}}\right)_{base} + \Delta_1 c_{\ell_{max}} + \Delta_2 c_{\ell_{max}} + \Delta_3 c_{\ell_{max}}$ (equation 4.1.1.4-a)

$= 1.30 + 0.07 + 0.15 - 0.13 = 1.39$

$\dfrac{C_{L_{max}}}{c_{\ell_{max}}} = 0.90$ (figure 4.1.3.4-21a)

$\Delta C_{L_{max}} = -0.105$ (figure 4.1.3.4-22)

$C_{L_{max}} = \left(\dfrac{C_{L_{max}}}{c_{\ell_{max}}}\right) c_{\ell_{max}} + \Delta C_{L_{max}}$ (equation 4.1.3.4-d)

$= (0.90)(1.39) - 0.105 = 1.15$

$\Delta a_{C_{L_{max}}} = 0.5^{o}$ (figure 4.1.3.4-21b)

Find C_{L_a}

$$\frac{A}{\kappa}\left[\beta^2 + \tan^2 \Lambda_{c/2}\right]^{1/2} = 8.60$$

$C_{L_a}/A = 0.59$ per rad (figure 4.1.3.2-49)

$$C_{L_a} = C_{N_a} = \left(\frac{C_{L_a}}{A}\right)A = (0.59)(9) = 5.31$$

$$a_0 = a_i - \frac{c_{\ell_i}}{c_{\ell_a}} = 0 - \frac{0.2}{0.113} = -1.77^{o} \text{ (equation 4.1.3.1-a)}$$

$$a_{C_{L_{max}}} = \frac{C_{L_{max}}}{C_{L_a}} + a_0 + \Delta a_{C_{L_{max}}} \text{ (equation 4.1.3.4-e)}$$

$$= \frac{1.15}{5.31/(57.3)} + (-1.77) + 0.5 = 11.14^{o}$$

Find $\left(C_{N_{aa}}\right)_{ref}$

$$C'_N \text{ @ } C_{L_{max}} = \frac{C_{L_{max}}}{\cos a_{C_{L_{max}}}} = \frac{1.15}{0.9815} = 1.17 \text{ (equation 4.1.3.3-c)}$$

$$(a_e)_{C_{L_{max}}} = a_{C_{L_{max}}} - a_0 = 12.91^{o}$$

$$\left(C_{N_{aa}}\right)_{ref} = \frac{C'_N \text{ @ } C_{L_{max}} - C_{N_a}\left(\frac{1}{2}\right)\sin 2(a_e)_{C_{L_{max}}}}{\sin (a_e)_{C_{L_{max}}}\left|\sin (a_e)_{C_{L_{max}}}\right|} \text{ (equation 4.1.3.3-d with } a_{C_{L_{max}}} = (a_e)_{C_{L_{max}}}$$

$$= \frac{1.17 - (5.31)\left(\frac{0.4355}{2}\right)}{(0.2235)^2} = \frac{0.0137}{0.0500} = 0.274$$

Find J

$C_1 = 0.43$, $C_2 = 1.09$ (figure 4.1.3.4-24b)

$$J = 0.3\,(C_1 + 1)\frac{A}{\beta}\cos \Lambda_{LE}\left\{(C_1 + 1)(C_2 + 1) - \left[\frac{(C_2 + 1)\,A \tan \Lambda_{LE}}{7}\right]^3\right\} \text{ (equation 4.1.3.3-e)}$$

$$= 0.3\,(1.43)\,\frac{9}{0.954}\,(0.9993)\left\{(1.43)\,(2.09) - \left[\frac{(2.09\,(9)\,(0.0384)}{7}\right]^3\right\}$$

$$= 12.10$$

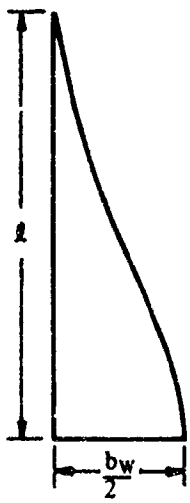
SKETCH (g)

6. Curved Wing

Given: The ogee wing of reference 29.



$A = 1.20 \quad b_w = 12.0$ in. $\quad \ell = 20.0$ in.

$M = 0.4$

Compute:

Wing slenderness parameter

$$\frac{b_w}{2\ell} = \frac{12.0}{2(20.0)} = 0.30$$

$$\sqrt{\frac{b_w}{2\ell}} = 0.548$$

Solution:

$$C_L = \frac{C_L}{\sqrt{\frac{b_w}{2\ell}}} \sqrt{\frac{b_w}{2\ell}} \quad \text{(equation 4.1.3.3-}\ell\text{)}$$

①	②	③	④

16	1.210		0.664
20	1.580		0.865

These calculated results are compared with test data in table 4.1.3.3-D at angles of attack of 4°, 8°, and 12°.

B. TRANSONIC

No specific charts are presented for determining the transonic lift characteristics of wings at high angles of attack. The best source of information of this type is experimental data on similar configurations, e.g., reference 10. If such information is not immediately available, the method of the following paragraphs may be used as a guide to obtain trends.

For thin, low-aspect-ratio, conventional wings, an indication of the lift characteristics at high angles of attack at transonic speeds may be obtained by the following procedure:

1. Calculate the complete lift curves for $M = 0.6$ and $M = 1.4$ by the methods of paragraphs A and C, respectively, of this section.

2. Obtain the wing lift-curve slope at low angles of attack, as outlined in Section 4.1.3.2, for intermediate Mach numbers.

3. Obtain the wing maximum-lift variation with Mach number and angle of attack for maximum lift as outlined in Section 4.1.3.4.

4. Using as a guide the information determined in the first three steps, construct the approximate lift curves for the range of Mach numbers between 0.6 and 1.4.

For thick, high-aspect-ratio, conventional wings the same procedure may be used except that the transonic lift-curve slopes obtained from Section 4.1.3.2 apply only to the first few degrees of angle of attack and may be misleading if extrapolated to higher angles. Section 4.1.3.2 gives a more detailed discussion of this problem. For any wing, local nonlinearities at high angles of attack are likely to exist at Mach numbers between 0.8 and 0.95. Again, it is best to use experimental data.

C. SUPERSONIC

Conventional, swept wings at supersonic speeds may be conveniently divided into two major categories:

Wings with subsonic leading edges, that is, wings for which $\beta/\tan \Lambda_{LE} < 1$

Wings with supersonic leading edges, that is, wings for which $\beta/\tan \Lambda_{LE} > 1$

The supersonic-leading-edge category may be further subdivided according to whether or not the leading-edge shock is attached or detached.

In order to provide continuity between these various supersonic regimes, as well as with the subsonic regime, the normal-force equation, 4.1.3.3-a, has again been used. As before, the first term is based on linear theory and the second accounts for nonlinear effects. The linear term is taken from Section 4.1.3.2 and the nonlinear coefficient $C_{N_{\alpha\alpha}}$ is given in the charts of this section. The charts of this section are based on references 11 through 19. Table 4.1.3.3-E presents substantiation data and compares the results obtained with this method to experimental data for the subsonic-leading-edge case. Tables 4.1.3.3-F and 4.1.3.3-G present corresponding information for the supersonic-leading-edge cases. Table 4.1.3.3-F is for wings having attached shocks at low angles and detached shocks at high angles. Table 4.1.3.3-G is for wings having detached shocks throughout the angle-of-attack range.

Supersonic Normal-Force Coefficient of Wings with Subsonic Leading Edges

For conventional, swept wings with subsonic leading edges at supersonic free-stream Mach numbers, the nonlinear character of the normal-force curve is primarily a function of $\beta/\tan \Lambda_{LE}$ and to a lesser degree of C_{N_α}. The lift characteristics are similar to the subsonic maximum-lift characteristics of low-aspect-ratio wings, in that the maximum-lift coefficient first increases, then decreases with increasing aspect ratio (see Section 4.1.3.4). As with the subsonic wings, the critical leading-edge sweep angle at which reversal occurs seems to lie between 60° and 65°. Therefore, the influence of C_{N_α} has been separated into two regimes. In the first regime, for sweep angles less than 62.5°, C_{N_α} is used directly as derived from linear theory. In the second regime, for sweep angles greater than 62.5°, the lift-curve slope is modified by an empirical correction factor.

DATCOM METHOD

The procedure for finding the supersonic pseudo normal-force coefficient C'_N of a straight-tapered wing with subsonic leading edges at high angles of attack is as follows:

Step 1. The normal-force-curve slope C_{N_α} for the conventional wing is found from Section 4.1.3.2. This includes the modifying effect of thickness on normal-force-curve slope as given in figure 4.1.3.2-60. In this figure, thickness is represented by $\delta_\perp$, the semiwedge angle normal to the leading edge of wings having sharp leading edges, and by $\Delta y_\perp$, the leading-edge parameter normal to the leading edge of wings having rounded leading edges.

Step 2. An empirical parameter E is found from one of the two following equations:

$$E = C_{N_\alpha} \quad \text{for} \quad \frac{\tan \Lambda_{LE}}{1.92} \leqslant 1$$

$$E = C_{N_\alpha} \left[\frac{\tan \Lambda_{LE}}{1.92} + C \left(\frac{\tan \Lambda_{LE}}{1.92} - 1 \right) \right] \quad \text{for} \quad \frac{\tan \Lambda_{LE}}{1.92} > 1$$

where C is a thickness term from figure 4.1.3.3-59a and $\delta_\perp$ in this figure is the leading-edge parameter normal to the leading edge; for wings having rounded leading edges, $\delta_\perp = \tan^{-1} \dfrac{\Delta y_\perp}{5.85}$

Step 3. The nonlinear coefficient $C_{N_{\alpha\alpha}}$ is found from figure 4.1.3.3-59b as a function of $E \left(\dfrac{\beta}{\tan \Lambda_{LE}} \right)$ and the angle-of-attack parameter $\left[\dfrac{\left(C_{N_\alpha} \right)_{\text{theory}}}{C_{N_\alpha}} \right] \beta \tan \alpha$ or its reciprocal.

Step 4. The total lift and approximate normal-force coefficients are obtained using equation 4.1.3.3-a; i.e.,

$$\frac{C_L}{\cos \alpha} = C'_N = C_{N_\alpha} \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin \alpha \, |\sin \alpha|$$

Application of this technique is illustrated by the sample problem on pages 4.1.3.3-34 through 4.1.3.3-36.

Supersonic Normal-Force Coefficient of Wings With Supersonic Leading Edges

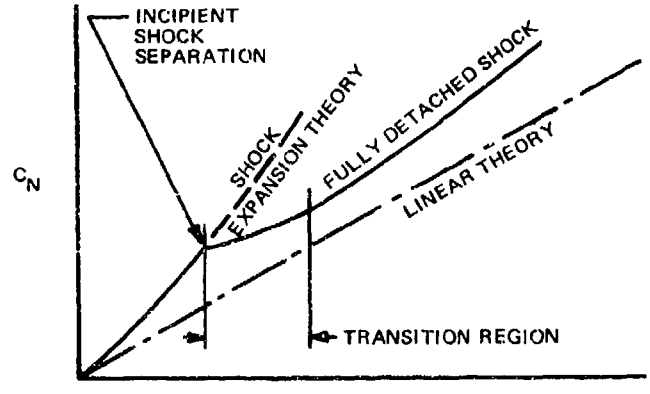
For conventional wings with supersonic leading edges, the wing leading-edge shock may or may not be attached, depending on the angle of attack and the wing thickness.

When the shock is attached, shock-expansion theory (summarized in reference 20) gives accurate results. Shock-expansion theory states that the pressures acting on a wing are a direct function of the airfoil thickness and profile shape. For the total integrated normal forces, however, little accuracy is lost if the wing is assumed to be a flat plate.

Thickness effects may not be neglected, even approximately, in determining the conditions under which an attached shock will detach. A shock will start to detach whenever the sum of the angle of attack and the semiwedge angle, both measured normal to the leading edge, exceeds the value of an expression given in reference 20; in other words,

$$a_\perp + \delta_\perp > \frac{4}{3\sqrt{3}\,(\gamma+1)} \frac{(M_\perp^2 - 1)^{3/2}}{M_\perp^2}$$

where $M_\perp$ is the Mach number normal to the leading edge and $\gamma = 1.4$. This function is plotted in figure 4.1.3.3-61b. As the angle of attack is increased beyond this value for incipient shock detachment, an angle-of-attack transition region occurs (see sketch (h)), wherein the normal-force characteristics of a given wing gradually come to resemble those of a similar wing of somewhat greater thickness at a lower angle of attack. When the angle of attack reaches the upper limit of the transition region, the shock may be considered to be fully detached.



SKETCH (h)

For wings where the leading-edge shock is detached, no theory exists for the prediction of normal forces. However, examination of experimental data shows that a nonlinear force coefficient may be defined and presented in much the same way as was done for supersonic wings with subsonic leading edges. This is to be expected, since a local subsonic region exists near the leading edge when the shock is detached. For these wings, the nonlinear coefficient $C_{N_{aa}}$ is a function of C_{N_a} only.

DATCOM METHOD

The first step is to determine whether the leading-edge shock is attached or detached at zero angle of attack. This is determined by using figure 4.1.3.3-61b. Set $\delta_{eff_\perp}$ (see figure 4.1.3.3-61b) equal to the semiwedge angle of the wing perpendicular to the wing leading edge $\delta_\perp$, and calculate the upstream Mach number perpendicular to the wing leading edge at zero angle of attack by

$$(M_\perp)_{\alpha=0} = M_\infty \sqrt{1 - \sin^2 \Lambda_{LE}}$$

The leading-edge shock condition is then determined by the boundary of figure 4.1.3.3-61b. If the shock is detached, follow procedure (1) below; if the shock is attached, follow procedure (2).

1. Supersonic Wings With Detached Shock at Zero Angle of Attack

The procedure for finding the supersonic pseudo normal-force coefficient C'_N at high angles of attack of a straight-tapered wing with supersonic leading edges and with a detached shock is as follows:

Step 1.a. The derivative C_{N_α} is calculated from Section 4.1.3.2. C_{N_α} is the theoretical normal-force-curve slope of figures 4.1.3.2-56a through 4.1.3.2-56g multiplied by the empirical thickness correction of figure 4.1.3.2-60.

Step 1.b. The equivalent lift-curve slope E is calculated from the appropriate one of the two following equations:

$$E = C_{N_\alpha} \text{ for } \frac{\tan \Lambda_{LE}}{1.92} \leq 1.0$$

$$E = C_{N_\alpha}\left[\frac{\tan \Lambda_{LE}}{1.92} + C\left(\frac{\tan \Lambda_{LE}}{1.92} - 1\right)\right] \text{ for } \frac{\tan \Lambda_{LE}}{1.92} > 1$$

where C is determined from figure 4.1.3.3-59a as a function of the semiwedge angle normal to the leading edge.

The nonlinear coefficient $C_{N_{\alpha\alpha}}$ is determined from figure 4.1.3.3-60a as a function of E and the angle-of-attack parameter used as the abscissa.

Step 1.c. The total lift and approximate normal-force coefficients are obtained using equation 4.1.3.3-a; i.e.,

$$\frac{C_L}{\cos \alpha} = C'_N = C_{N_\alpha} \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin \alpha \, |\sin \alpha|$$

2. Supersonic Wings With Attached Shock at Zero Angle of Attack

The procedure for finding the supersonic pseudo normal-force coefficient C'_N at high angles of attack of a straight-tapered wing with supersonic leading edges and with an attached shock is as follows:

Step 2.a. The derivative C_{N_α} is calculated from Section 4.1.3.2. C_{N_α} is the theoretical normal-force slope of figures 4.1.3.2-56a through 4.1.3.2-56g multiplied by the empirical thickness correction of figure 4.1.3.2-60.

Step 2.b. Determine the angle of attack α^* at which the shock will start to detach. This is obtained by using figure 4.1.3.3-61b. For unswept wings, the value of $\delta_{eff_\perp}$ at the start of shock detachment is obtained from figure 4.1.3.3-61b at $M_\perp = M_\infty$. Then the angle of attack at which the shock will start to detach is determined by

$$\alpha^* = \delta_{eff_\perp} - \delta_\perp$$

For swept wings $\delta_{eff_\perp}$ must be determined by graphical interpolation, since there is an interdependence between the Mach number and the angle of attack normal to the leading edge. These relations for swept wings are

$$M_\perp = M_\infty \sqrt{1 - \sin^2 \Lambda_{LE} \cos^2 \alpha}$$

$$\alpha_\perp = \tan^{-1}\left(\frac{\tan \alpha}{\cos \Lambda_{LE}}\right)$$

where M_∞ is the free-stream Mach number, $M_\perp$ is the Mach number perpendicular to the leading edge, α is the wing angle of attack, and $\alpha_\perp$ is the angle of attack normal to the leading edge.

For a selected range of α's, calculate $\delta_{eff_\perp}$ and $M_\perp$ using the above equations and the relationship

$$\delta_{eff_\perp} = \alpha_\perp + \delta_\perp$$

Then plot $M_\perp$ versus $\delta_{eff_\perp}$ on figure 4.1.3.3-61b. The intersection of this curve and the boundary curve of figure 4.1.3.3-61b determines the value of $\delta_{eff_\perp}$ at which the shock will start to detach. Then the angle of attack at which the shock will start to detach is determined by

$$\alpha^* = \tan^{-1}\left[\tan(\delta_{eff_\perp} - \delta_\perp) \cos \Lambda_{LE}\right]$$

Step 2.c. The angle-of-attack-transition increment between incipient shock detachment and full detachment is now determined from figure 4.1.3.3-61a. To enter this figure, the nonlinear normal-force coefficient at incipient shock separation $C^*_{N_{\alpha\alpha}}$ must be known. This is read

from figure 4.1.3.3-60b by entering on the abscissa $\left(\beta \tan \alpha \text{ or } \frac{1}{\beta \tan \alpha}\right)$ at the angle of attack corresponding to incipient shock separation as already calculated in step 2.b.

$C^*_{N_{\alpha\alpha}} = C_{N_{\alpha\alpha}}$ is then read from the appropriate β-curve.

Step 2.d. The total lift and approximate normal-force coefficients may now be calculated for the three different angle-of-attack ranges using equation 4.1.3.3-a; i.e.,

$$\frac{C_L}{\cos \alpha} = C'_N = C_{N_\alpha} \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin \alpha \, |\sin \alpha|$$

where

C_{N_α} is from step 2.a.

$C_{N_{\alpha\alpha}}$ for the attached-shock range is read from figure 4.1.3.3-60b.

$C_{N_{\alpha\alpha}}$ for the fully-detached-shock range is read from figure 4.1.3.3-60a in the manner outlined in step 1.b. of the section on detached shocks.

$C_{N_{\alpha\alpha}}$ in the transition range is interpolated graphically or calculated analytically from the linear-interpolation formula

$$C_{N_{\alpha\alpha}} = C^*_{N_{\alpha\alpha}} - \left(\frac{\alpha - \alpha^*}{\alpha' - \alpha^*}\right)\left(C^*_{N_{\alpha\alpha}} - C'_{N_{\alpha\alpha}}\right)$$

In the above formula the starred quantities are measured at incipient-shock-separation conditions, and primed quantities are measured at the end of the transition region, where the shock is fully detached.

Application of this technique is illustrated by sample problem 2 on pages 4.1.3.3-36 through 4.1.3.3-39.

Sample Problems

1. Supersonic Pseudo-Normal-Force Coefficient of Wing With Subsonic Leading Edge.

Given: Wing 4a of reference 15.

$A = 0.562 \quad \lambda = 0 \quad \Lambda_{LE} = 82^\circ \quad M = 6.9; \quad \beta = 6.83$

Airfoil: 5-percent-thick (free-stream direction) double wedge with maximum thickness at 50-percent chord

Compute:

C_{N_α} (Section 4.1.3.2)

$\delta_\perp$, semiwedge angle normal to wing leading edge

$$\delta_\perp = \frac{\text{semiwedge angle}}{\cos \Lambda_{LE}} = \frac{\frac{1}{2}\left(\frac{0.05}{0.5}\right)}{0.1392}(57.3) = 20.55^\circ$$

$$\frac{\beta}{\tan \Lambda_{LE}} = 0.960 \text{ (subsonic leading edge)}$$

$$A \tan \Lambda_{LE} = 4.00$$

$$\left(C_{N_\alpha}\right)_{\text{theory}} = 0.573 \text{ per rad (figure 4.1.3.2-56a)}$$

$$\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{\text{theory}}} = 0.750 \text{ (figure 4.1.3.2-60)}$$

$$C_{N_\alpha} = (0.750)(0.573) = 0.430 \text{ per rad}$$

Empirical Parameter E

$$\frac{\tan \Lambda_{LE}}{1.92} = 3.71; \text{ therefore, use second equation listed under step 1.b. of Datcom method.}$$

$$C_{N_\alpha} \frac{\tan \Lambda_{LE}}{1.92} = 1.595$$

$C = 1.30$ (figure 4.1.3.3-59a)

$$E = C_{N_\alpha}\left[\frac{\tan \Lambda_{LE}}{1.92} + C\left(\frac{\tan \Lambda_{LE}}{1.92} - 1\right)\right]$$

$$= 0.43\ [3.71 + (1.30)(3.71 - 1)]$$

$$= 3.11$$

$$E \frac{\beta}{\tan \Lambda_{LE}} = 3.00$$

Solution:

$$C'_N = C_{N_\alpha} \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin \alpha\ |\sin \alpha| \text{ (equation 4.1.3.3-a)}$$

$C_{N_{aa}}$ is obtained from figure 4.1.3.3-59b.

2. Supersonic Pseudo-Normal-Force Coefficient of Wing with Supersonic Leading Edge

Given: Wings 1A and 1B of reference 15

$A = 2.31 \quad \lambda = 0 \quad \Lambda_{LE} = 60^\circ \quad M = 6.91; \ \beta = 6.83$

Airfoil: 5-percent-thick double wedge with maximum thickness at 50-percent chord

Compute:

Determine whether the leading-edge shock is attached or detached at zero angle of attack.

$\delta_\perp$ = semiwedge angle normal to wing leading edge

$$\delta_\perp = \frac{\text{semiwedge angle}}{\cos \Lambda_{LE}} = \frac{\frac{1}{2}\left(\frac{0.05}{0.5}\right)}{0.500}(57.3) = 5.7^\circ$$

$$(M_\perp)_{\alpha=0} = M_\infty \sqrt{1 - \sin^2 \Lambda_{LE}} = 3.45$$

For the conditions $(M_\perp)_{\alpha=0} = 3.45$ and $\delta_{eff_\perp} = 5.7^\circ$, the leading-edge shock is attached (see figure 4.1.3.3-61b); therefore, follow procedure (2) of the Datcom method.

C_{N_α} (Section 4.1.3.2)

$$\frac{\tan \Lambda_{LE}}{\beta} = 0.254$$

$$A \tan \Lambda_{LE} = 4.00$$

$$\left(C_{N_\alpha}\right)_{theory} = 0.586 \text{ per rad (figure 4.1.3.2-56a)}$$

$$\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}} = 1.0 \text{ (figure 4.1.3.2-60)}$$

$$C_{N_\alpha} = 0.586 \text{ per rad}$$

Determine the angle of attack for which the shock will start to detach (α^*).

① α (deg)	② $\tan\alpha$	③ $\frac{\tan\alpha}{\cos\Lambda_{LE}}$	④ $\alpha_\perp$ ($\tan^{-1}$ ③) (deg)	⑤ $\delta_{eff_\perp}$ ($\alpha_\perp + \delta_\perp$) (deg)	⑥ $\cos\alpha$	⑦ $M_\perp = M_\infty\sqrt{1 - \sin^2\Lambda_{LE}\cos^2\alpha}$
4	0.0699	0.1399	7.96	13.7	0.9976	3.48
8	0.1450	0.2901	16.18	21.9	0.9903	3.55

24	0.4452	0.8904	41.68	47.4	0.9135	4.22

Plot $\delta_{eff_\perp}$ versus $M_\perp$ on figure 4.1.3.3-61b. At the intersection of this curve and the boundary curve of figure 4.1.3.3-61b, read $\delta_{eff_\perp}$ at the start of shock detachment.

$$\delta_{eff_\perp} = 38.5^o$$

$$\alpha^* = \tan^{-1}\left[\tan\left(\delta_{eff_\perp} - \delta_\perp\right)\cos\Lambda_{LE}\right]$$

$$= \tan^{-1}\left[\tan\left(38.5 - 5.7\right)\cos 60^o\right]$$

$$= \tan^{-1}\left(0.3223\right) = 17.9^o$$

Solution: Angles of Attack for Fully Attached Shock

$$C'_N = C_{N_\alpha} \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin\alpha \, |\sin\alpha| \qquad \text{(equation 4.1.3.3-a)}$$

$C_{N_{\alpha\alpha}}$ is obtained from figure 4.1.3.3-60b.

①	②	③	④	⑤	⑥	⑦
α (deg)	$\beta \tan\alpha$	$C_{N_{\alpha\alpha}}$ fig. 4.1.3.3-60b	$C_{N_{\alpha\alpha}} \sin^2\alpha$	$C_{N_\alpha} \frac{\sin 2\alpha}{2}$	C'_N eq. 4.1.3.3-a ④ + ⑤	C_L $(C'_N \cos\alpha)$

D. HYPERSONIC

At hypersonic speeds, the calculation of surface pressures on wings is complicated by several interrelated phenomena. These include the boundary layer, the shock wave, heat transfer between the wing and the gas, dissociation, and ionization. The relative importance of each of these phenomena as they affect the aerodynamic characteristics of wings traveling at hypersonic speeds has not been fully assessed.

Boundary layers affect the surface pressures by the displacement of the inviscid flow. This displacement of the flow also affects the shock-wave pattern and hence the surface pressures. At very low Reynolds numbers the inviscid flow between the boundary layer and the shock wave is entirely absorbed by the boundary layer, and the boundary layer interacts directly with the shock wave. In general, the Reynolds number decreases with increasing Mach number along the flight corridor because of the low densities at the altitudes associated with flight at high hypersonic speeds. Thus boundary-layer effects become important at the higher hypersonic speeds.

Because of aerodynamic heating at hypersonic speeds, lifting surfaces usually use blunt leading edges. Detached shocks are thus present ahead of the wing leading edge. Pressures on the surface near the leading edge behind the detached shock are large compared to oblique-shock, inviscid, flat-plate values at the same angle of attack. This "overpressure" decays with distance from the leading edge in a manner that depends on the free-stream Mach number, leading-edge radius, Reynolds number, and heat-transfer characteristics.

An empirical method presented in references 21 and 22 attempts to account for these Reynolds-number and detached-shock effects. This method combines inviscid-flow theory, blast-wave theory, and a viscous-interaction parameter. The examples presented in references 21 and 22 give some idea of the magnitude of these effects on the surface pressures. Because of the scarcity of test data, however, the range of applicability of this method is undetermined. The accuracy claimed in the references is ±15 percent.

Heat transfer between the gas and the wing surface affects the boundary-layer thickness and hence the surface pressures. The hotter the boundary layer, the thicker it becomes, and vice versa. Gas properties, notably the viscosity and ratio of specific heats, change with temperature. Increasing temperature increases the viscosity and decreases the specific-heat ratio. An indication of the effect of surface temperature on pressure distribution is shown in reference 22.

At high speed and/or low altitudes the extreme temperatures behind the detached shock wave cause dissociation of the atmospheric molecules into their atomic constituents. Under conditions of still higher temperature the atoms ionize and the gas becomes a conducting medium. These phenomena are generally restricted to the leading-edge region. Chapter VIII of reference 23 treats these problems.

Small-disturbance theory has yielded many useful hypersonic similarity forms both for two-dimensional sections and for axisymmetric bodies (chapter II of reference 23). Hypersonic similarity is basically limited to low angles of attack and slender bodies, although successful applications have been made that do not meet these conditions. The hypersonic-similarity concept is discussed and used in Section 4.2.1.2.

The only simple closed-form solution available for the estimation of the normal-force curve of blunt wings at hypersonic speeds is obtained from Newtonian or impact theory (reference 23). Newtonian theory assumes that the component of momentum normal to the surface is canceled (flow remains parallel to the surface after impact), giving rise to a normal force. Several modifications of Newtonian theory that have been developed are discussed in paragraph D of Section 4.2.1.1.

Newtonian theory does not account for many of the real gas interaction effects previously discussed. At high angles of attack or at high Mach numbers the surface pressures attributable to these interactions are small compared to the impact pressures. At low angles of attack or low Mach numbers they are no longer small compared to the impact pressures.

Newtonian theory also assumes that the pressures on the leeward surfaces (those not "seen" from the free-stream direction) are equal to the ambient pressure. Again, this is a good approximation at high angles of attack or high Mach numbers, because the actual pressures on the leeward surfaces compared to those on the forward-facing areas are small. At low Mach numbers or angles of attack the leeward pressures are no longer small compared to the positive pressures, and Newtonian theory gives less accurate results.

The general field of hypersonic flow is treated in references 23 and 24.

DATCOM METHOD

The curves of figures 4.1.3.3-59b through 4.1.3.3-60b are based on test data for the high supersonic Mach numbers and converge to Newtonian-theory flat-plate values for high hypersonic Mach numbers. It is recommended that these charts be used in conjunction with the normal-force-curve-slope information from paragraph C of Section 4.1.3.2 to obtain the total normal-force curve of wings in hypersonic flow.

4.1.3.4 WING MAXIMUM LIFT

Methods are presented in this section for estimating the maximum lift of wings at subsonic, transonic, supersonic, and hypersonic speeds.

A. SUBSONIC

At subsonic speeds the wing maximum lift of high-aspect-ratio wings is directly related to the maximum lift of the wing airfoil section, with planform geometry of secondary importance. However, as the wing aspect ratio decreases, the wing planform shape becomes increasingly more significant. This is especially true for low-aspect-ratio delta-wing or non-straight-tapered planforms where leading-edge vortex effects are prevalent.

The complexity of modern wing designs (twisted wings with varying airfoil sections) precludes the application of empirical methods that yield consistently good results. Thus, the use of more exact theory is necessary for estimating maximum lift. Method 1 presented below requires the user to employ the most accurate wing spanwise-loading computer program available. In case no such program is available to the user, two additional empirical methods are presented. Method 2 is applicable to high-aspect-ratio configurations with constant-section untwisted wings. Method 3 is applicable to low-aspect-ratio configurations with constant-section untwisted wings.

Wing lift characteristics do not change discontinuously from one aspect-ratio regime to another. However, because of the different approaches used in Methods 2 and 3, values calculated by Method 2 will not necessarily match exactly the values of Method 3 for a border-line aspect-ratio configuration.

In general, however, the differences in values obtained by the two methods for the border-line aspect ratios should be small.

Flow Separation and Stalling Characteristics

For high-aspect-ratio wings, the three-dimensional maximum lift and stalling characteristics are, as a first approximation, determined by section properties (see Sections 4.1.1.3 and 4.1.1.4). There are, however, certain three-dimensional effects that may become important. These include the spanwise variations of induced camber and angle of attack, and the effect of spanwise pressure gradient on the boundary layer.

Because of these effects, the stall of three-dimensional wings, even untwisted wings of constant airfoil section, usually starts at some spanwise station and rapidly spreads with increasing angle of attack. Highly tapered wings tend to stall at the tips, while untapered wings tend to stall at the root.

On swept wings the induced effects combine to promote stall at the tip. The induced camber at the tip is negative and the induced angle of attack is high. The spanwise pressure gradient tends to draw the boundary layer from the wing root to the tip. All of these factors promote separation at the wing tip and suppress it at the root. It is therefore very difficult to prevent tip separation at high angles of attack on highly swept wings.

Regardless of where the separation first appears, it is the type of separation that determines the maximum lift. Trailing-edge separation, which is characteristic of thick wings, always results in a loss in maximum lift compared to the airfoil-section maximum lift. Leading-edge separation, where

the flow rolls up into a spanwise vortex, as on thin swept wings, results in an increase in normal force. The magnitude of the increase is related to the strength of the leading-edge vortex. These effects are illustrated by the variations of maximum lift with wing thickness at high sweep angles, as shown in Figure 4.1.3.4-21a. For more details regarding wing flow separation and stalling characteristics, the reader is referred to References 1 and 2.

Reynolds-Number Effects

The salient aspects of the Reynolds-number discussion presented in Reference 2 are presented below. From the available test data results, there appear to be essential differences between the Reynolds-number effects of thin airfoils ($t/c \approx 0.06$), of moderately thick airfoils ($t/c \approx 0.12$), and of thick airfoils ($t/c \approx 0.18$).

The maximum lift of thin airfoils is relatively constant up to a Reynolds number of 10×10^6; but when this Reynolds number is exceeded, the value of maximum lift begins to increase.

With moderately thick airfoils a very large increase of the maximum lift with increasing Reynolds number is found at low Reynolds numbers. However, at Reynolds numbers above 4 to 6×10^6, the maximum lift tends to remain about constant.

The maximum lift of thick airfoils increases gradually up to high Reynolds numbers. At Reynolds numbers above 15×10^6, the maximum lift tends to remain constant.

Mach-Number Effects

Mach-number effects on the maximum lift of unswept, thick wings are quite severe, starting as low as $M = 0.15$. This is to be expected from the analogy with section characteristics (see Section 4.1.1.4). For swept wings the losses due to Mach number are much less than they are for straight wings of a given thickness.

Mach-number effects are due in part to the larger pressure gradients associated with compressible flow. These larger pressure gradients can cause the boundary layer to separate at a lower lift value, thus resulting in a lower maximum lift with increasing Mach number. Large decreases in maximum lift can be related to the problem of shock-induced separation. For a complete discussion of the compressibility effects, the reader is referred to Reference 3.

Interference Effects

It must be recognized that the maximum lift of the wing alone, as given in this section, may be substantially altered by interference effects. The addition of fuselages, nacelles, pylons, and other protuberances can markedly change the aerodynamic characteristics of a given configuration near the stall. Interference effects of this type are discussed in Section 4.3.1.4.

DATCOM METHODS

Method 1

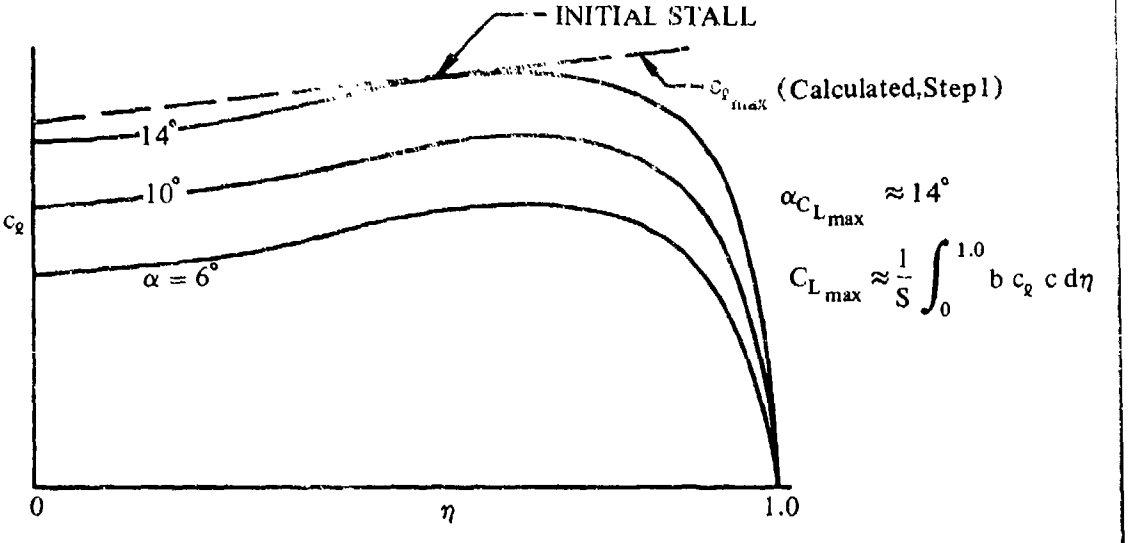
The following method requires that the user have at his disposal an accurate wing spanwise-loading computer program, e.g., a lifting-surface theory computer program. If no such computer program is available, Methods 2 and 3 may be used to approximate the wing maximum lift.

Method 1 is limited to moderately swept configurations where leading-edge vortex effects are not significant. In addition, the spanwise location where stall is first detected should be limited to one local chord-length away from the wing root and tip sections.

Application of the method is as follows:

Step 1. Determine the section $c_{\ell_{max}}$ across the entire span of the wing, based on the appropriate Mach number and local Reynolds number, using Section 4.1.1.4. If section test data are available, they should be used whenever possible, and the appropriate corrections made for Mach number, Reynolds number, and surface roughness as given in Section 4.1.1.4.

Step 2. Plot the section $c_{\ell_{max}}$ from Step 1 as a function of spanwise station η (see Sketch (a)).



SKETCH (a)

Step 3. Apply the wing spanwise-loading method over a range of angle of attack until a value of the local wing loading coincides or exceeds the local wing $c_{\ell_{max}}$ calculated from Step 1 (see Sketch (a)). The angle of attack at which the spanwise loading coincides with the calculated $c_{\ell_{max}}$ value determines the angle of attack and spanwise position for initial stall. An approximate spanwise location where the stall will first occur can be calculated for an untwisted, tapered wing by

$$\eta_{stall} = 1 - \lambda \qquad 4.1.3.4\text{-a}$$

where λ is the wing taper ratio.

Step 4. Integrate the spanwise loading that coincides with the calculated $c_{\ell_{max}}$ value to obtain the wing $C_{L_{max}}$ value.

Although no substantiation of this method is presented, design experience has shown that the accuracy of this method is superior to that of both Methods 2 and 3.

Method 2

The following method is derived empirically, based on the experimental data of References 4 through 10. This method should therefore be restricted to those untwisted, constant-section, straight-tapered, high-aspect-ratio configurations that satisfy the following relationship:

$$A > \frac{4}{(C_1 + 1)\cos \Lambda_{LE}} \qquad 4.1.3.4\text{-b}$$

where

A is the wing aspect ratio.

C_1 is given as a function of taper ratio in Figure 4.1.3.4-24b.

Λ_{LE} is the sweep of the wing leading edge.

Border-line configurations are those that satisfy the following relationship:

$$\frac{3}{(C_1 + 1)\cos \Lambda_{LE}} \leqslant A \leqslant \frac{4}{(C_1 + 1)\cos \Lambda_{LE}} \qquad 4.1.3.4\text{-c}$$

For these aspect ratios either Method 2 or Method 3 may be used.

If neither Equation 4.1.3.4-b nor -c is satisfied, the low-aspect-ratio procedure presented in Method 3 may be used.

The subsonic maximum lift and angle of attack for maximum lift for those untwisted, constant-section, high-aspect-ratio configurations that satisfy Equation 4.1.3.4-b or -c are given as follows:

$$C_{L_{max}} = \left(\frac{C_{L_{max}}}{c_{\ell_{max}}}\right) c_{\ell_{max}} + \Delta C_{L_{max}} \qquad 4.1.3.4\text{-d}$$

$$\alpha_{C_{L_{max}}} = \frac{C_{L_{max}}}{C_{L_\alpha}} + \alpha_0 + \Delta\alpha_{C_{L_{max}}} \qquad 4.1.3.4\text{-e}$$

The first term on the right side of Equation 4.1.3.4-d is the maximum lift coefficient at M = 0.2, and the second term is the lift increment to be added for Mach numbers between 0.2 and 0.6.

$\frac{C_{L_{max}}}{c_{\ell_{max}}}$ is obtained from Figure 4.1.3.4-21a.

$c_{\ell_{max}}$ is the section maximum lift coefficient at M = 0.2 obtained from Tables 4.1.1-A, -B, or from Section 4.1.1.4.

$\Delta C_{L_{max}}$ is a Mach-number correction obtained from Figure 4.1.3.4-22.

C_{L_α} is the wing lift-curve slope (per degree) for the Mach number under consideration, obtained from test data or Section 4.1.3.2.

α_0 is the wing zero-lift angle for the appropriate Mach number, obtained from test data or Section 4.1.3.1.

$\Delta\alpha_{C_{L_{max}}}$ is obtained from Figure 4.1.3.4-21b. Note that this figure is valid for all subsonic Mach numbers up to 0.6.

The leading-edge parameter Δy, which does not explicitly appear in the equations, must be used in reading values from the charts. The value of Δy is for a streamwise airfoil section and is expressed in percent chord and obtained or approximated from Figure 2.2.1-8.

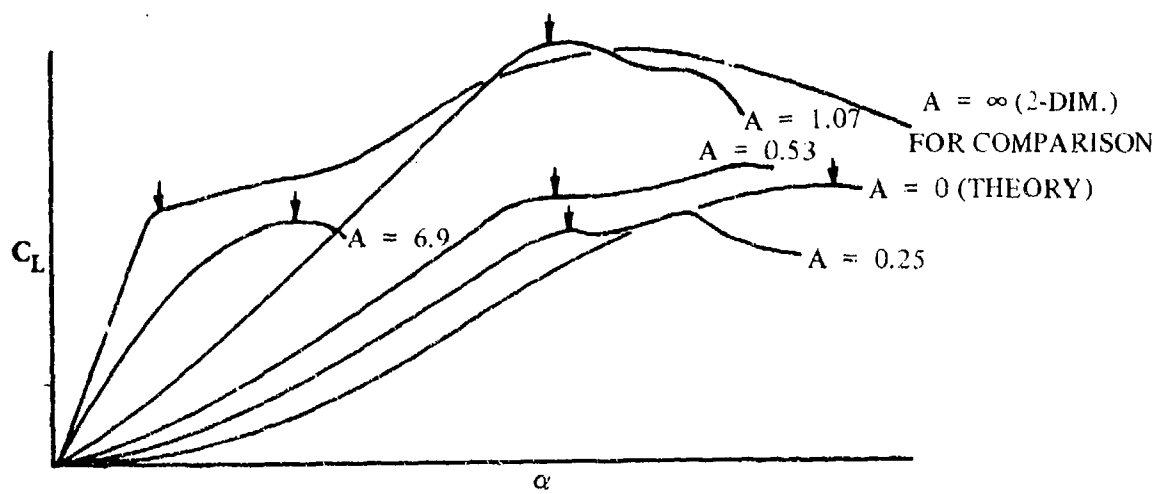
In calculating $\alpha_{C_{L_{max}}}$ the value of $C_{L_{max}}$ calculated from Equation 4.1.3.4-d is used as the numerator of the first term of Equation 4.1.3.4-e.

A comparison of test values of $C_{L_{max}}$ and $\alpha_{C_{L_{max}}}$ (based on the calculated $C_{L_{max}}$ value) with the corresponding values calculated by this method is shown in Table 4.1.3.4-A.

Method 3.

The following is an empirically derived method (Reference 11) that is applicable to untwisted, symmetrical-section, low-aspect-ratio wings.

Low-aspect-ratio wings at subsonic speeds exhibit extreme nonlinearities in the lift curve at high angles of attack, as shown in the accompanying sketch. Multiple lift peaks exist for many configurations. The charts of this section are for the first peak, as shown by the arrows in Sketch (b).



SKETCH (b)

For thin, low-aspect-ratio wings, Reynolds-number effects are small. Within the Reynolds-number and thickness limitations listed on Figures 4.1.3.4-23 through -25, Reynolds number is considered to have no effect.

This method is applicable to those low-aspect-ratio configurations (without considering Mach-number effects) that satisfy the following relationship:

$$A < \frac{3}{(C_1 + 1)\cos \Lambda_{LE}} \qquad 4.1.3.4\text{-f}$$

where

A is the wing aspect ratio.

C_1 is given as a function of taper ratio in Figure 4.1.3.4-24b.

Λ_{LE} is the sweep of the wing leading edge.

Border-line configurations are those that satisfy the following relationship:

$$\frac{3}{(C_1 + 1)\cos \Lambda_{LE}} \leq A \leq \frac{4}{(C_1 + 1)\cos \Lambda_{LE}} \qquad 4.1.3.4\text{-c}$$

For these aspect ratios either Method 2 or Method 3 may be used.

If neither Equation 4.1.3.4-f nor 4.1.3.4-c is satisified, the high-aspect-ratio procedure presented in Method 2 may be used.

The subsonic maximum lift and angle of attack for maximum lift for those untwisted, symmetrical-section, low-aspect-ratio configurations that satisfy Equation 4.1.3.4-f or -c are given as follows:

$$C_{L_{max}} = (C_{L_{max}})_{base} + \Delta C_{L_{max}} \qquad 4.1.3.4\text{-g}$$

$$\alpha_{C_{L_{max}}} = (\alpha_{C_{L_{max}}})_{base} + \Delta\alpha_{C_{L_{max}}} \qquad 4.1.3.4\text{-h}$$

where

$(C_{L_{max}})_{base}$ is the base value of $C_{L_{max}}$ obtained from Figure 4.1.3.4-23a if the position of maximum airfoil-section thickness is forward of the 35-percent-chord point. If the maximum thickness is aft of this point, Figure 4.1.3.4-23b is used. For slab-sided wings the maximum-thickness point is considered to be the first chord-point at which the thickness reaches a maximum. The value of Δy, the leading-edge parameter used in reading these two charts, is obtained or approximated with the aid of Figure 2.2.1-8.

$\Delta C_{L_{max}}$ is the change in the base maximum-lift value. It is obtained from Figure 4.1.3.4-24a as a function of taper ratio, aspect ratio, leading-edge sweep, and Mach number.

$(\alpha_{C_{L_{max}}})_{base}$ is the base value of $\alpha_{C_{L_{max}}}$ obtained from Figure 4.1.3.4-25a. It is a function of aspect ratio, taper ratio, leading-edge sweep, and Mach number.

$\Delta\alpha_{C_{L_{max}}}$ is the change in the base value of angle of attack at maximum lift. It is obtained from Figure 4.1.3.4-25b as a function of taper ratio, aspect ratio, leading-edge sweep, and Mach number.

A comparison of test values of $C_{L_{max}}$ and $\alpha_{C_{L_{max}}}$ with the corresponding values calculated by this method (where $\alpha_{C_{L_{max}}}$ is based on the calculated $C_{L_{max}}$ value) is shown in Table 4.1.3.4-B.

Sample Problems

1. Method 2

Given: The following high-aspect-ratio configuration.

$A = 5.0$ $\quad \Lambda_{LE} = 46.6^{o}$ $\quad \lambda = 0.565$

$R_{\ell} = 2 \times 10^{6}$ $\quad$ Airfoil: NACA 64A010 (free-stream direction)

$C_{L_{\alpha}} = 0.061$ per deg $\quad \alpha_{0} = 0$ $\quad M = 0.4$

Compute:

Determine if the above configuration satisfies the high-aspect-ratio requirement for Method 2, as stipulated in Equation 4.1.3.4-b; i.e.,

$$A > \frac{4}{(C_1 + 1)\cos\Lambda_{LE}}$$

$C_1 = 0.24$ (Figure 4.1.3.4-24b)

$$\frac{4}{(C_1 + 1)\cos\Lambda_{LE}} = \frac{4}{(0.24 + 1.0)\cos 46.6^{o}} = \frac{4}{(1.24)(0.6871)} = 4.69$$

$A = 5.0 > 4.69$

The high-aspect-ratio requirement is satisfied; therefore, Method 2 is applicable to the above configuration.

Determine the maximum lift coefficient at $M = 0.40$

$\Delta y = 2.12\%\, c$ (Figure 2.2.1-8)

$c_{\ell_{max}} = 1.23$ (Table 4.1.1-B)

$\frac{C_{L_{max}}}{c_{\ell_{max}}} = 0.83$ (Figure 4.1.3.4-21a)

$\Delta C_{L_{max}} = -0.053$ (Figure 4.1.3.4-22, interpolated)

$$C_{L_{max}} = \left(\frac{C_{L_{max}}}{c_{\ell_{max}}}\right) c_{\ell_{max}} + \Delta C_{L_{max}} \quad \text{(Equation 4.1.3.4-d)}$$

$$= (0.83)(1.23) + (-0.053)$$

$$= 1.02 - 0.053$$

$$= 0.97$$

Determine the angle of attack at the wing maximum lift

$\Delta\alpha_{C_{L_{max}}} = 6.7^{o}$ (Figure 4.1.3.4-21b)

$$\alpha_{C_{L_{max}}} = \frac{C_{L_{max}}}{C_{L_\alpha}} + \alpha_0 + \Delta\alpha_{C_{L_{max}}} \quad \text{(Equation 4.1.3.4-e)}$$

$$= \frac{0.97}{0.061} + 0 + 6.7$$

$$= 15.9 + 6.7$$

$$= 22.6^{o}$$

2. Method 3

Given: The following low-aspect-ratio configuration.

$A = 1.0$ $\Lambda_{LE} = 45^{o}$ $\lambda = 0.3$

Airfoil: NACA 0005 (free-stream direction)

Maximum thickness @ 30% chord $M = 0.6$

Compute:

Determine if the above configuration satisfies the low-aspect-ratio requirement for Method 3 as stipulated in Equation 4.1.3.4-f; i.e.,

$$A < \frac{3}{(C_1 + 1)\cos\Lambda_{LE}}$$

$C_1 = 0.5$ (Figure 4.1.3.4-24b)

$$\frac{3}{(C_1 + 1)\cos \Lambda_{LE}} = \frac{3}{(0.5 + 1.0)\cos 45^{O}} = \frac{3}{(1.5)(0.7071)} = 2.83$$

$A = 1 < 2.83$

The low-aspect-ratio requirement is satisfied; therefore, Method 3 is applicable to the above configuration.

Determine the maximum-lift coefficient at M = 0.6

$\Delta y = 1.37\%\ c$ (Figure 2.2.1-8)

$\beta = \sqrt{1 - M^2} = \sqrt{1 - (0.6)^2} = 0.80$

$C_2 = 0.91$ (Figure 4.1.3.4-24b)

$$(C_1 + 1)\frac{A}{\beta}\cos \Lambda_{LE} = (0.5 + 1.0)\frac{1}{0.80}\cos 45^{O} = 1.326$$

$(C_{L_{max}})_{base} = 1.12$ (Figure 4.1.3.4-23a)

$(C_2 + 1)\, A \tan \Lambda_{LE} = (0.91 + 1.0)(1) \tan 45^{O} = 1.91$

$\Delta C_{L_{max}} = -0.08$ (Figure 4.1.3.4-24a)

$C_{L_{max}} = (C_{L_{max}})_{base} + \Delta C_{L_{max}}$ (Equation 4.1.3.4-g)

$= 1.12 - 0.08$

$= 1.04$

Determine the angle of attack at the wing maximum lift

$(\alpha_{C_{L_{max}}})_{base} = 30.8^{O}$ (Figure 4.1.3.4-25a)

$A \cos \Lambda_{LE} [1 + (2\lambda)^2] = 1.0 \cos 45^{O} [1 + (0.6)^2] = 0.962$

$\Delta\alpha_{C_{L_{max}}} = 3.5^{O}$ (Figure 4.1.3.4-25b)

$\alpha_{C_{L_{max}}} = (\alpha_{C_{L_{max}}})_{base} + \Delta\alpha_{C_{L_{max}}}$ (Equation 4.1.3.4-h)

$= 30.8 + 3.5$

$= 34.3^{O}$

B. TRANSONIC

No method for high-aspect-ratio wings is presented herein in the transonic speed regime. However, for low-aspect-ratio wings an empirical method is presented.

For low-aspect-ratio wings, the maximum lift at transonic speeds was found to be basically a function of the same variables that were used in the subsonic speed regime (see References 12 through 15). Therefore, the design charts for the transonic speed regime are based on the subsonic design charts.

It should be noted that the transonic maximum-lift coefficient of thick wings may be limited by adverse pitching-moment variations and severe buffeting.

Both of these limitations are associated with extensive flow separation arising from compressibility, shock waves, and adverse pressure gradients.

DATCOM METHOD

The maximum lift and angle of attack at maximum lift for untwisted, symmetrical-section, low-aspect-ratio configurations are determined for Mach numbers between 0.6 and 1.2 by the following procedure:

Step 1. Calculate the maximum lift and angle of attack at maximum lift for the wing under consideration at M = 0.6 by using Method 3 of Paragraph A of this section.

Step 2. Determine the increments in maximum lift and angle of attack at maximum lift at the desired Mach number from Figures 4.1.3.4-26a through -26c. These increments are then added directly to the values obtained at M = 0.6 in Step 1; i.e.,

$$(C_{L_{max}})_M = (C_{L_{max}})_{M=0.6} + \Delta C_{L_{max}} \qquad 4.1.3.4\text{-i}$$

$$(\alpha_{C_{L_{max}}})_M = (\alpha_{C_{L_{max}}})_{M=0.6} + \Delta\alpha_{C_{L_{max}}} \qquad 4.1.3.4\text{-j}$$

A comparison of experimental data with results based on this method is presented in Table 4.1.3.4-C.

Sample Problem

Given: The same low-aspect-ratio configuration used in Sample Problem 2 of Paragraph A.

$A = 1.0$ $\Lambda_{LE} = 45^{\circ}$ $\lambda = 0.3$

Airfoil NACA 0005

$C_{L_{max}} = 1.04$

$\alpha_{C_{L_{max}}} = 34.3^{o}$

$C_2 = 0.91$

$C_1 = 0.50$

} Sample Problem 2, Paragraph A

$M = 1.0$

Compute:

$(C_2 + 1) A \tan \Lambda_{LE} = (0.91 + 1)(1.0)(1.0) = 1.91$

$C_3 = 1.0$ (Figure 4.1.3.4-26b)

$C_3 (C_1 + 1) A \cos \Lambda_{LE} = (1.0)(0.50 + 1)(1.0)(0.7071) = 1.06$

$\Delta C_{L_{max}} = 0$ (Figure 4.1.3.4-26a)

$(C_1 + 1) A \cos \Lambda_{LE} = (0.50 + 1)(1.0)(0.7071) = 1.06$

$\Delta\alpha_{C_{L_{max}}} = 0.5^{o}$ (Figure 4.1.3.4-26c)

Solution:

$C_{L_{max}} = (C_{L_{max}})_{M=0.6} + \Delta C_{L_{max}}$ (Equation 4.1.3.4-i)

$= 1.04 + 0$

$= 1.04$

$\alpha_{C_{L_{max}}} = (\alpha_{C_{L_{max}}})_{M=0.6} + \Delta\alpha_{C_{L_{max}}}$ (Equation 4.1.3.4-j)

$= 34.3 + 0.5$

$= 34.8^{o}$

C. SUPERSONIC

At supersonic speeds the lift is limited by geometric considerations rather than by flow separation. That is, maximum lift is reached when the component of the normal force in the lift direction ceases to increase with angle of attack.

The governing geometric parameters for the determination of maximum lift are those that influence the wing lift-curve slope; i.e., aspect ratio, sweep, taper ratio, and Mach number. It is therefore logical that a good correlating term might include the lift-curve slope. One such parameter that gives good results and is used here is $C_{N_\alpha}/(4/\beta)$.

DATCOM METHOD

For the supersonic case the most accurate way of determining the wing maximum lift is by calculating the normal-force curve (using Sections 4.1.3.2 and 4.1.3.3) and converting it to a lift curve by means of the relationship $C_L = C'_N \cos\alpha$. However, design charts are presented herein for a more rapid procedure of estimating the wing maximum lift.

For Mach numbers greater than 1.4, the supersonic maximum lift and angle of attack at maximum lift may be approximated using Figures 4.1.3.4-27a and -27b. These figures are based on empirical data taken from References 16 through 26, and are presented as a function of C_{N_α} and Mach number ($\beta = \sqrt{M^2 - 1}$). The lift-curve slope C_{N_α} is obtained from test data or from Paragraph C of Section 4.1.3.2.

A comparison of experimental data with results based on this method is presented in Table 4.1.3.4-D.

Sample Problem

Given: The configuration of Reference 18.

$A = 1.96$ $\quad \Lambda_{LE} = 64^\circ$ $\quad C_{N_\alpha} = 1.72$ per rad $\quad M = 2.32$

Compute:

$$\beta = \sqrt{M^2 - 1}$$

$$= \sqrt{(2.32)^2 - 1}$$

$$= 2.093$$

$$\frac{1}{M} = \frac{1}{2.32} = 0.431$$

$$\frac{C_{N_\alpha}}{4/\beta} = \frac{(1.72)(2.093)}{4} = 0.900 \text{ per rad}$$

Solution:

$C_{L_{max}} = 1.02$ (Figure 4.1.3.4-27a)

$\alpha_{C_{L_{max}}} = 41.4^\circ$ (Figure 4.1.3.4-27b)

These compare with test values of $C_{L_{max}}$ of 0.98 and $\alpha_{C_{L_{max}}}$ of 43.8° from Reference 18.

D. HYPERSONIC

The supersonic method of Paragraph C above is used to estimate $C_{L_{max}}$ and $\alpha_{C_{L_{max}}}$ at hypersonic speeds. The parameters that affect $C_{L_{max}}$ at the lower hypersonic Mach numbers are the same as those for the supersonic speeds, i.e., planform parameters. At high hypersonic speeds, $C_{L_{max}}$ is determined primarily by flow impact on the wing lower surface. Newtonian flow theory thus provides a reasonable approximation for $C_{L_{max}}$ values in this speed range. The high hypersonic limit ($1/M \rightarrow 0$) of Figures 4.1.3.4-27a and 4.1.3.4-27b is derived using the Newtonian equation

$$C_L = 2 \sin^2 \alpha \cos \alpha \qquad \text{4.1.3.4-k}$$

4.1.4 WING PITCHING MOMENT

The pitching-moment characteristics of aerodynamic surfaces are conventionally represented by specifying the wing aerodynamic-center location or the wing center of pressure.

The aerodynamic center is defined as that point on the wing plane of symmetry about which the pitching moment is invariant with lift, i.e., $\frac{dC_m}{dC_L} = 0$, for power-off flight of a rigid vehicle at a given Mach number.

The relationship between the wing aerodynamic center and the wing pitching-moment slope about any arbitrary point on the wing root chord is then given by the equation (neglecting wing drag):

$$\frac{dC_m}{dC_L} = -\left(n - \frac{x_{a.c.}}{c_r}\right)\frac{c_r}{c} \qquad 4.1.4\text{-a}$$

where

$\frac{x_{a.c.}}{c_r}$ is the chordwise distance from the wing apex to the aerodynamic center, measured in root chords, positive aft

n is the chordwise distance from the wing apex to the point about which the pitching moment is desired, measured in root chords, positive aft

$\frac{c_r}{c}$ is the ratio of the root chord to the pitching-moment reference chord, generally taken as the wing M.A.C.

$\frac{dC_m}{dC_L}$ is the slope of the wing pitching-moment coefficient about the point n with respect to the lift coefficient

The usefulness of the aerodynamic-center concept lies principally in the convenient way in which it presents pitching-moment information in the linear lift range. Within this range the forces on a wing are simply represented by a lift vector of varying magnitude acting through the aerodynamic center and a constant moment about the a.c. equivalent to the wing zero-lift moment.

The aerodynamic-center concept is often used beyond the linear lift range by specifying the locus of points at which $\frac{dC_m}{dC_L}$ is zero, as a function of lift (or angle of attack). The a.c. curve thus defined represents the successive points at which the surface has "neutral stability."

Center of pressure is defined as that point at which the wing total resultant force intersects the wing chord, i.e., it is the point on the wing chord at which $C_m = 0$.

If the wing center-of-pressure location is known, the wing pitching moment about any other point on the wing chord may be calculated, provided the direction of the resultant-force vector on the wing is also known. This fact, which is apparent from geometrical considerations, is reflected in the equations for determining the moment coefficient from the center of pressure. There are two cases, as follows:

A. Resultant-force vector perpendicular to the wing surface:

$$C_m = -\left(n - \frac{x_{cp}}{c_r}\right)\frac{c_r}{c}\, C_N \qquad 4.1.4\text{-b}$$

B. Resultant-force vector in the lift direction (perpendicular to the free stream):

$$C_m = -\left(n - \frac{x_{cp}}{c_r}\right)\frac{c_r}{c}\, C_L \cos\alpha \qquad 4.1.4\text{-c}$$

In the above equations $\frac{x_{cp}}{c_r}$ is the chordwise distance from the wing apex to the wing center of pressure, measured in

root chords, positive aft.

Since at low angles of attach the resultant-force vector on wings is essentially in the lift direction (see Section 4.1.3), equation 4.1.4-c is applicable. At high angles of attack, the resultant force is more nearly normal to the wing chord and thus equation 4.1.4-b is the more applicable. However, equation 4.1.4-b may also be used at low angles of attack. For the remainder of this Section, it is assumed that equation 4.1.4-b holds at all angles of attack, and that the C_N in this equation is equivalent to the C'_N as defined and discussed in Section 4.1.3.

In the linear lift range, the locations of the center of pressure and the aerodynamic center are the same for wings having symmetrical profiles but not the same for wings having cambered profiles.

Two sets of charts are presented in subsequent Sections. The charts for the linear lift range present the aerodynamic-center location of wings as a function of planform parameters. The charts for the nonlinear lift range give the wing center-of-pressure location also as a function of planform parameters. The two groups of charts taken together permit the calculation of the complete-pitching-moment curve from 0° to 90° angle of attack for symmetrical wings.

For cambered wings, no specific method is presented for calculating the pitching moments beyond the linear lift range. However, for angles of attack beyond the stall, it is not likely that there will be much difference between the pitching moments of symmetrical wings and those of cambered wings.

4.1.4.1 WING ZERO-LIFT PITCHING MOMENT

The methods presented in this section are restricted to subsonic speeds. In the transonic and supersonic speed regimes it is suggested that reference be made to experimental data.

A. SUBSONIC

Two methods are presented for estimating the wing zero-lift pitching moment. Method 1 is general and is applicable to the majority of moderately swept configurations. It is not advisable to use Method 1 for configurations having a quarter-chord-sweep angle greater than 45°. Method 2 is taken from Reference 1 and is applicable only at M = 0.2 for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with large thickness ratios; i.e., $0.10 \leqslant t/c \leqslant 0.30$.

DATCOM METHODS

Method 1

The low-speed zero-lift pitching moment based on the product of the wing area and mean aerodynamic chord $S_W \bar{c}_W$, for untwisted, constant-section wings with elliptical loading may be approximated by

$$\left(C_{m_0}\right)_{\theta=0} = \frac{A \cos^2 \Lambda_{c/4}}{A + 2 \cos \Lambda_{c/4}} c_{m_0} \qquad 4.1.4.1\text{-a}$$

where c_{m_0} is the section pitching-moment coefficient at zero lift, obtained from Section 4.1.2.1. The airfoil section is defined parallel to the free stream.

For airfoil sections varying along the span

$$\left(C_{m_0}\right)_{\theta=0} = \frac{A \cos^2 \Lambda_{c/4}}{A + 2 \cos \Lambda_{c/4}} \left(\frac{c_{m_{0_{root}}} + c_{m_{0_{tip}}}}{2}\right) \qquad 4.1.4.1\text{-b}$$

where $c_{m_{0_{root}}}$ and $c_{m_{0_{tip}}}$ are the section pitching-moment coefficients at zero lift of the root and tip sections, respectively, both defined parallel to the free stream.

For wings with linear twist, lifting-line theory may be used as in Reference 2 to obtain C_{m_0} by

$$C_{m_0} = \left(C_{m_0}\right)_{\theta=0} + \left(\frac{\Delta C_{m_0}}{\theta}\right)\theta \qquad 4.1.4.1\text{-c}$$

where

$\left(C_{m_0}\right)_{\theta=0}$ is the zero-lift pitching-moment coefficient of an untwisted wing, obtained by using either Equation 4.1.4.1-a or Equation 4.1.4.1-b.

$\frac{\Delta C_{m_0}}{\theta}$ is the change in wing zero-lift pitching-moment coefficient due to a unit change in linear wing twist. This parameter is obtained from Figure 4.1.4.1-5.

θ is the twist of the wing tip with respect to the root section, in degrees (negative for washout). A linear spanwise twist distribution is assumed (all constant-percent points of local chords lie in straight lines along the span).

The effect of Mach number on the wing zero-lift pitching-moment coefficient, up to the critical Mach number, is presented in Figure 4.1.4.1-6. This chart, based on test data, gives the ratio of wing or wing-body zero-lift pitching-moment coefficient in compressible flow to that in incompressible flow. When using this chart, no correction should be made to the section c_{m_0} value. The use of this chart should give reasonable results up to M = 0.8. However, beyond this point the chart should be used with caution, since test data often show abrupt changes in zero-lift pitching moment at high transonic speeds.

The limited availability of test data, coupled with the fact that the wing zero-lift pitching-moment coefficient does not lend itself to accurate experimental measurement, precludes substantiation of this method.

Method 2

This semiempirical method is taken from Reference 1, ignoring the small wing-planform nose-radius effects. The semiempirical method was developed by using the test results of Reference 1, correlated with the theoretical predictions based on lifting-surface theory. Because of its semiempirical nature, the method should be restricted to M = 0.2 conditions for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with the following geometric characteristics:

$$0.58 \leqslant A \leqslant 2.55$$

$$0 \leqslant \lambda \leqslant 0.3$$

$$63^{\circ} \leqslant \Lambda_{LE} \leqslant 80^{\circ}$$

$$0.10 \leqslant t/c \leqslant 0.30$$

$$\Lambda_{TE} = 0$$

For round-nosed-planform configurations the reader is referred to Reference 1, where three different planform nose-radius models were tested. No incremental nose planform effects are presented here because of their probable configuration dependence.

The wing zero-lift pitching-moment coefficient may be approximated by the following procedure:

Step 1. Determine the section zero-lift pitching-moment coefficient c_{m_0} for the particular airfoil under consideration. Lifting-surface theory was used in the method formulation of Reference 1 to estimate the section zero-lift pitching-moment coefficient. For this reason it is recommended that lifting-surface theory be used, if available, for the prediction of c_{m_0}.

If lifting-surface theory is not available, c_{m_0} may be estimated by using test data; e.g., those listed in Tables 4.1.1-A and -B.

Step 2. Determine a wing zero-lift pitching moment $\left(C_{m_0}\right)_{\text{theory}}$ uncorrected for thickness effects from Figure 4.1.4.1-7 as a function of sweep, taper ratio, and section zero-lift pitching moment. (The value of Λ_c is defined as $\Lambda_c = 90^\circ - \Lambda_{LE}$.)

Step 3. Calculate the wing zero-lift pitching moment C_{m_0}, based on the wing area and wing root chord $S_W c_r$, using the following

$$C_{m_0} = \left[\frac{C_{m_0}}{\left(C_{m_0}\right)_{\text{theory}}}\right] \left(C_{m_0}\right)_{\text{theory}} \qquad 4.1.4.1\text{-d}$$

where

$\dfrac{C_{m_0}}{\left(C_{m_0}\right)_{\text{theory}}}$ is the ratio of zero-lift pitching moment corrected for thickness effects to the uncorrected zero-lift pitching moment. This ratio is obtained from Figure 4.1.4.1-8 as a function of thickness, planform geometry, and the uncorrected wing zero-lift pitching moment.

$\left(C_{m_0}\right)_{\text{theory}}$ is the zero-lifting pitching-moment coefficient uncorrected for thickness effects obtained above in Step 2.

For the particular configurations to which this method is applicable, insufficient data are available to determine the usefulness of Figure 4.1.4.1-6 for estimating Mach number effects.

No substantiation of this method is possible because of the lack of wing-alone low-aspect-ratio test data having thickness ratios of $0.10 \leqslant t/c \leqslant 0.30$.

Sample Problems

1. Method 1

Given: The following straight-tapered wing of Reference 3.

$A = 6.0$ $\quad \lambda = 0.5$ $\quad \Lambda_{c/4} = 9.67^\circ$ $\quad \theta = 0$ $\quad$ Low speed

NACA 2301.2 airfoil (free-stream direction)

Compute:

$c_{m_0} = -0.014$ (Table 4.1.1-A)

Solution:

$$\left(C_{m_0}\right)_{\sigma=0} = \frac{A \cos^2 \Lambda_{c/4}}{A + 2 \cos \Lambda_{c/4}} c_{m_0} \quad \text{(Equation 4.1.4.1-a)}$$

$$= \frac{6(0.9858)^2}{6 + 2(0.9858)} (-0.014)$$

$$= -0.010$$

This compares with a test value of -0.012 from Reference 3.

2. Method 2

Given: The following constant-section, low-aspect-ratio, clipped-delta configuration.

$A = 0.823$ $\lambda = 0.18$ $\Lambda_{LE} = 73.5^{\circ}$

NACA 2412 airfoil $M = 0.2$ $\Lambda_c = 16.5^{\circ}$ (complement of leading-edge sweep)

Compute:

$c_{m_0} = -0.047$ (Table 4.1.1-A)

$4 \tan \Lambda_c (1 + \pi\lambda^2 \tan \Lambda_c) = 4(0.2962)\left[1 + \pi(0.18)^2 (0.2962)\right] = 1.2205$

$\left(C_{m_0}\right)_{\text{theory}} = -0.010$ (Figure 4.1.4.1-7)

$$\frac{C_{m_0}}{\left(C_{m_0}\right)_{\text{theory}}} = 0.91 \quad \text{(Figure 4.1.4.1-8)}$$

$$C_{m_0} = \left[\frac{C_{m_0}}{\left(C_{m_0}\right)_{\text{theory}}}\right] \left(C_{m_0}\right)_{\text{theory}} \quad \text{(Equation 4.1.4.1-d)}$$

$$= (0.91)(-0.010)$$

$$= -0.0091$$

4.1.4.2 WING PITCHING-MOMENT-CURVE SLOPE

This section presents methods for calculating the pitching-moment characteristics of wings at low angles of attack at any speed.

The pitching-moment characteristics are generally presented in terms of the wing aerodynamic center. The aerodynamic center (Section 4.1.4) is that point about which the wing pitching moment is invariant with lift. Thus the pitching-moment slope based on the product of the wing area and the mean aerodynamic chord $S_w\bar{c}_w$ about any specified point on the wing chord line may be described by the following equation:

$$\frac{dC_m}{dC_L} = \left(n - \frac{x_{a.c.}}{c_r}\right) \frac{c_r}{\bar{c}} \qquad 4.1.4.2\text{-a}$$

where

$\frac{x_{a.c.}}{c_r}$ is the distance from the wing apex to the aerodynamic center measured in root chords, positive aft.

n is the distance from the wing apex to the desired moment reference center measured in root chords, positive aft.

$\frac{c_r}{\bar{c}}$ is the ratio of the root chord to the mean aerodynamic chord.

A. SUBSONIC

At subsonic speeds methods are presented for predicting the aerodynamic center of the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal wings)

Non-Straight-Tapered Wings

Double-delta wings

Cranked wings

Curved (Gothic and ogee) wings

These three general categories of non-straight-tapered wings are illustrated in Sketch (a) of Section 4.1.3.2. Their wing-geometry parameters are presented in Section 2.2.2.

Two methods are presented for estimating the wing pitching-moment-curve slope for straight-tapered wings. Method 1 is general and is applicable to the majority of configurations. Method 2 is applicable only at $M = 0.2$ for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with large thickness ratios; i.e., $0.10 \leq t/c \leq 0.30$.

All of the basic theories for calculating wing lift apply to wing pitching moments also. However, as is discussed in Section 4.1.3.2, there is no guarantee that a theory that gives accurate results for lift also gives accurate values for moments.

One theory that does give accurate results for both lift and moments of straight-tapered wings over the entire aspect-ratio range is the lifting-surface theory of Reference 1. Although the computation difficulties of this method are not as formidable as those of some other lifting-surface theories, solutions are nevertheless limited to certain specific planforms.

Most of the currently available methods that are applicable to a wide range of configurations are based largely on empirical data. A semiempirical method of this type is presented in Reference 2. The procedure of this reference uses certain simplified theories (see References 3 and 4) to define limiting locations for the aerodynamic-center positions as the wing aspect ratio approaches zero or infinity. For intermediate aspect ratios, some 150 experimental points from 40 different reports are used as a guide in fairing curves between the theoretically determined limits. In this way generalized charts are constructed for straight-tapered wings of arbitrary aspect ratio and taper ratio. Comparison between the aerodynamic-center locations given by the semiempirical method of Reference 2 and the available lifting-surface solutions of Reference 1 shows a high degree of correlation. The charts of Reference 2 also agree well with the other available semiempirical methods of less extensive scope, such as that of Reference 5.

In the Datcom the graphical aerodynamic-center information presented is basically that of Reference 2. However, the charts are presented in a slightly different form, and the effects of Mach number are added by means of the Prandtl-Glauert compressibility correction rule. The design charts for predicting the aerodynamic center are applicable only within the linear-lift range. Thus the charts apply to wings of very low aspect ratio at only very low angles of attack. These charts are directly applicable to straight-tapered wings. In treating non-straight-tapered wings, the wing is divided into two wing panels and the individual lift and aerodynamic center for each panel are used to establish the aerodynamic center for the composite wing.

Within the linear-lift range, profile parameters such as mean camber line, thickness, leading-edge shape, and others appear to have only minor influence on the aerodynamic-center location of either straight-tapered or non-straight-tapered wings.

Reynolds number, on the other hand, can have an appreciable effect. Reference 6 indicates that for a wing of aspect ratio 3 with a 3-percent biconvex section, the aerodynamic center can vary as much as 8 percent of the wing root chord between the Reynolds numbers 2.4×10^6 and 8×10^6. Although this aerodynamic-center shift appears to be larger than usual, it does serve to indicate that wind-tunnel test conditions, such as tunnel turbulence level, model support system, and Reynolds number, can have an important bearing on the experimentally measured aerodynamic chord locations.

DATCOM METHODS

Straight-Tapered Wings

Method 1

Figures 4.1.4.2-26a through 4.1.4.2-26f present the a.c. location for straight-tapered wings at subsonic speeds. These charts give the a.c. location as a fraction of the wing root chord. The charts are based on planform characteristics only and thus are most applicable to low-aspect-ratio wings.

The characteristics of high-aspect-ratio wings are primarily determined by the wing two-dimensional section characteristics. For most airfoil sections the a.c. location is at or near the MAC quarter-chord point. However, if greater accuracy is desired, the a.c. location for the particular airfoil section under consideration may be determined from Section 4.1.2.2.

The applicability of the subsonic portions of Figures 4.1.4.2-26a through 4.1.4.2-26f is limited to $M \leqslant 0.6$. The form of presentation of the charts does not permit an indication of this limit in a manner that is applicable in all situations. Beyond M = 0.6 the a.c. location tends to become dependent on wing profile thickness and shape, as indicated in Paragraph B of this section.

However, for swept wings with $t/c \leqslant 0.04$ the thickness effects are much reduced, and Figures 4.1.4.2-26a through 4.1.4.2-26f may be applied to Mach numbers somewhat higher than M = 0.6.

Method 2

This semiempirical method is taken from Reference 7, ignoring the small wing-planform nose-radius effects. The semiempirical method was developed by using the test results of Reference 7, correlated with the theoretical predictions based on lifting-surface theory. Because of its semiempirical nature, the method should be restricted to M = 0.2 conditions for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with the following geometric characteristics:

$$0.10 \leqslant t/c \leqslant 0.30$$

$$0.58 \leqslant A \leqslant 2.55 ,$$

$$0 \leqslant \lambda \leqslant 0.3$$

$$63^{\circ} \leqslant \Lambda_{LE} \leqslant 80^{\circ}$$

$$\Lambda_{TE} = 0$$

The nonlinear region of the pitching-moment curve for configurations described above may be approximated by using Method 2 of Section 4.1.4.3.

For round-nosed-planform configurations the reader is referred to Reference 7, where three different planform nose-radius models were tested. No incremental nose planform effects are presented here because of their probable configuration dependence.

The wing pitching-moment-curve slope may be approximated by the following procedure:

Step 1. Calculate the aerodynamic-center location uncorrected for wing thickness effects by the following:

$$\frac{x_{a.c.}}{c_r} = \frac{\frac{2}{3}(1-\lambda) + \frac{1}{2}\left[1 - \frac{\lambda^2}{1+\lambda}\right] \pi \log_e\left(1 + \frac{A}{5}\right)}{1 + \pi \log_e\left(1 + \frac{A}{5}\right)} \qquad 4.1.4.2\text{-b}$$

Step 2. Determine the wing pitching-moment-curve slope uncorrected for wing thickness effects by using a modified form of Equation 4.1.4.2-a, i.e.,

$$\left(\frac{dC_m}{dC_L}\right)_{theory} = n - \frac{x_{a.c.}}{c_r}$$

where

n is the distance from the wing apex to the desired moment reference center, measured in root chords, positive aft. If the semiempirical procedure presented in Method 2 of Section 4.1.4.3 is to be used to determine the nonlinear pitching-moment characteristics, the determination of the moment reference center n is not arbitrary. The moment reference center in this case should be taken at the root-chord midpoint, i.e., $n = 0.5$.

$\frac{x_{a.c.}}{c_r}$ is the distance from the wing apex to the aerodynamic center, measured in root chords, positive aft. This term is obtained from Step 1 above and is uncorrected for thickness effects.

Step 3. Correct the pitching-moment-curve slope for thickness effects, based on the product of wing area and wing root chord $S_W c_r$, by

$$\frac{dC_m}{dC_L} = \left(\frac{dC_m}{dC_L}\right)_{theory} \left[\frac{dC_m/dC_L}{(dC_m/dC_L)_{theory}}\right] \qquad 4.1.4.2\text{-c}$$

where

$\left(\frac{dC_m}{dC_L}\right)_{theory}$ is the wing pitching-moment-curve slope from Step 2, uncorrected for thickness effects.

$\frac{dC_m/dC_L}{(dC_m/dC_L)_{theory}}$ is the wing-thickness-correction factor for the wing pitching-moment-curve slope. This parameter is obtained from Figure 4.1.4.2-29 as a function of $(dC_m/dC_L)_{theory}$ and thickness.

No substantiation of this method is possible because of the lack of low-aspect-ratio test data having wing thickness ratios of $0.10 \leq t/c \leq 0.30$.

Non-Straight-Tapered Wings

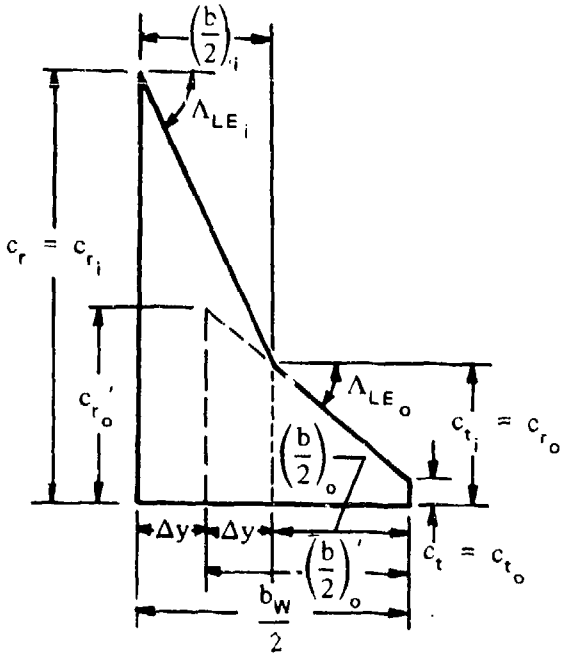
The method for predicting the a.c. location near zero lift of non-straight-tapered wings is taken from Reference 8. This method is used for all non-straight-tapered wings. The non-straight-tapered wing is divided into two panels with each panel having conventional, straight-tapered geometry. Then, for each of the constructed panels, the individual lift-curve slope and a.c. are estimated by

treating each constructed panel as a complete wing. The individual lift and a.c. location derived for each constructed panel are then mutually combined in accordance with an "inboard-outboard" weighted-area relationship to establish the predicted a.c. location for the basic non-straight-tapered wing. There is a difference between the construction geometry used to determine the inboard and outboard panels for the double-delta and cranked wings, and that for the curved wings. Application of the method requires that the wings be broken down as defined below.

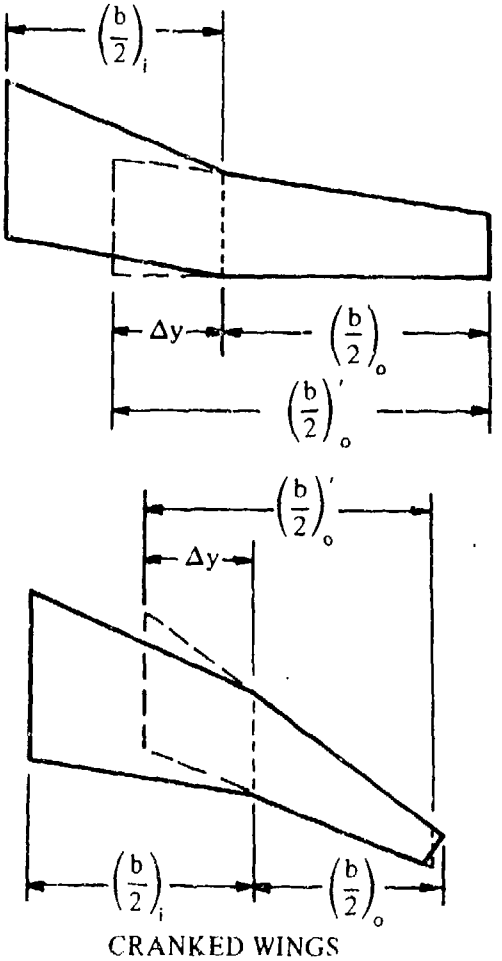
Double-Delta and Cranked Wings (see Sketch (a))

Inboard Panel – the inboard leading and trailing edges extended to the center line. The tip-chord span station is fixed at the break formed by the discontinuity in the sweep of the leading edge of the composite wing. The constructed inboard panel is designated by subscript i.

Outboard Panel – the leading and trailing edges of the main outboard panel extended inboard to the midpoint between the center line and the break formed by the discontinuity in the sweep of the leading edge of the composite wing. The main outboard panel is designated by subscript o and the constructed outboard panel is designated by a prime and a subscript o.



DOUBLE-DELTA WING



CRANKED WINGS

SKETCH (a)

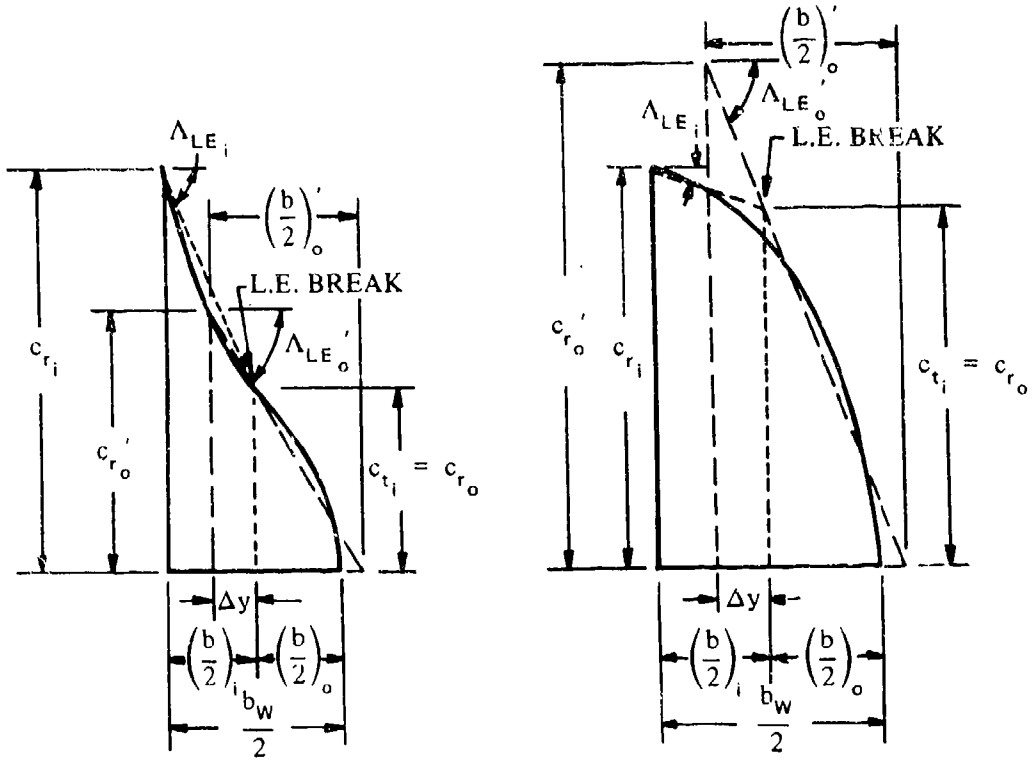
Many double-delta and cranked wings have non-straight trailing edges with the trailing-edge break occurring at a different span station from the leading-edge break. For such wings the irregular trailing-edge sweep angles of the divided panels are modified by using straight trailing-edge sweep angles for each panel, constructed so that the area moment about the respective wing-panel apex remains approximately the same.

Curved Wings (see Sketch (b))

The basic ogee and Gothic planforms must be modified to divide the wing into two panels having conventional, straight-tapered geometry. The modified inboard and outboard panels are designated in the same manner as noted in the double-delta- and cranked-wing breakdown. Both types of curved wings are divided by the following procedure:

1. The tip chord of the inboard panel is located at one-half of the curved wing semispan; i.e., $\left(\frac{b}{2}\right)_i = \left(\frac{b}{2}\right)_o = 0.50\left(\frac{b_w}{2}\right)$. This locates the span station of the leading-edge break, and tip-chord span station of the constructed inboard panel.

2. The root chord of the constructed outboard panel is located at one-fourth of the curved wing semispan; i.e., c_{r_o}' span station is at $(0.25)\left(\frac{b_w}{2}\right)$.



SKETCH (b)

3. The semispan of the constructed outboard panel is 0.85 times the semispan of the basic curved wing; i.e., $\left(\frac{b}{2}\right)'_o = 0.85\left(\frac{b_w}{2}\right)$. This locates the tip of the constructed outboard panel.

4. The tip chord of the constructed outboard panel is zero; i.e., $\lambda'_o = 0$.

5. The leading-edge sweep angles of the two panels are approximated by the use of straight-line segments as shown. Try to maintain an approximately constant area moment for the outboard panel about its apex.

The subsonic aerodynamic-center location of non-straight-tapered wings is obtained from the procedure outlined in the following steps:

Step 1. Divide the non-straight-tapered wing into inboard and outboard panels as discussed above, and determine their pertinent geometric parameters.

Step 2. Determine the lift-curve slope of the constructed inboard panel $\left(C_{L_\alpha}\right)_i$, from Figure 4.1.3.2-49, based on its respective area S_i.

Step 3. Determine the a.c. location of the constructed inboard panel as a fraction of the root chord of the constructed inboard panel $\left(\frac{x_{a.c.}}{c_r}\right)_i$ from Figure 4.1.4.2-26. This a.c. location is aft of the apex of the constructed inboard panel.

Step 4. Determine the lift-curve slope of the constructed outboard panel $\left(C_{L_\alpha}\right)'_o$, from Figure 4.1.3.2-49, based on its respective area S'_o.

Step 5. Determine the a.c. location of the constructed outboard panel as a fraction of the root chord of the constructed outboard panel $\left(\frac{x_{a.c.}}{c_r}\right)'_o$ from Figure 4.1.4.2-26. This a.c. location is aft of the apex of the constructed outboard panel.

Step 6. Convert the a.c. location determined in Step 5 to a fraction of the root chord of the constructed inboard panel and aft of the apex of the constructed inboard panel by

$$\frac{\left(x_{a.c.}\right)'_o}{c_{r_i}} = \left(\frac{x_{a.c.}}{c_r}\right)'_o \left(\frac{c'_{r_o}}{c_{r_i}}\right) - \frac{\Delta y}{c_{r_i}} \tan \Lambda_{LE_o} + \frac{b_i}{2c_{r_i}} \tan \Lambda_{LE_i} \qquad 4.1.4.2\text{-d}$$

Step 7. Calculate the non-straight-tapered-wing aerodynamic center, measured in wing root chords aft of the wing apex, by

$$\frac{x_{a.c.}}{c_r} = \frac{\left(C_{L_\alpha}\right)_i S_i \left(\frac{x_{a.c.}}{c_r}\right)_i + \left(C_{L_\alpha}\right)'_o S'_o \frac{\left(x_{a.c.}\right)'_o}{c_{r_i}}}{\left(C_{L_\alpha}\right)_i S_i + \left(C_{L_\alpha}\right)'_o S'_o} \qquad 4.1. .2\text{-e}$$

The limited availability of experimental data precludes the substantiation of this method for double-delta and cranked wings. No experimental wing-alone double-delta data are readily available for subsonic speeds. Test data for three wing-alone cranked-wing configurations are available. The results of the method applied to those configurations are compared with test results in the data summary presented as Table 4.1.4.2-A (taken from Reference 8).

On the other hand, for curved wings there are enough test data available for a limited substantiation of the method. A comparison of test data for four curved-wing configurations with $x_{a.c.}/c_r$ calculated by this method is presented as Table 4.1.4.2-B (taken from Reference 8). The table also includes two configurations which are wing-body combinations, but the bodies are very small and the wing planform projection effectively blankets nearly all of the body. All the wings investigated have straight trailing edges and one reflex curve in the leading edge. The ranges of Mach number and lift coefficient of the data are:

$$0.09 \leq M \leq 0.9$$

$$0 \leq C_L \leq 0.10$$

Sample Problems

1. Method 2

Given: The following straight-tapered, constant-section, low-aspect-ratio, clipped-delta configuration.

$A = 0.823$ $\quad \lambda = 0.18$ $\quad \Lambda_{LE} = 73.5^\circ$

NACA 2412 airfoil $\quad M = 0.2$

Compute:

$$\frac{x_{a.c.}}{c_r} = \frac{\frac{2}{3}(1-\lambda) + \frac{1}{2}\left[1 - \frac{\lambda^2}{1+\lambda}\right]\pi \log_e\left(1 + \frac{A}{5}\right)}{1 + \pi \log_e\left(1 + \frac{A}{5}\right)} \qquad \text{(Equation 4.1.4.2-b)}$$

$$= \frac{\frac{2}{3}(1-0.18) + \frac{1}{2}\left[1 - \frac{(0.18)^2}{1+0.18}\right]\pi \log_e\left(1 + \frac{0.823}{5}\right)}{1 + \pi \log_e\left(1 + \frac{0.823}{5}\right)}$$

$$= 0.527$$

$$\left(\frac{dC_m}{dC_L}\right)_{theory} = n - \frac{x_{a.c.}}{c_r} \qquad \text{(Modified form of Equation 4.1.4.2-a)}$$

$$= 0.50 - 0.527 \quad = -0.027$$

$$\frac{dC_m/dC_L}{(dC_m/dC_L)_{theory}} = 0.935 \qquad \text{(Figure 4.1.4.2 -29)}$$

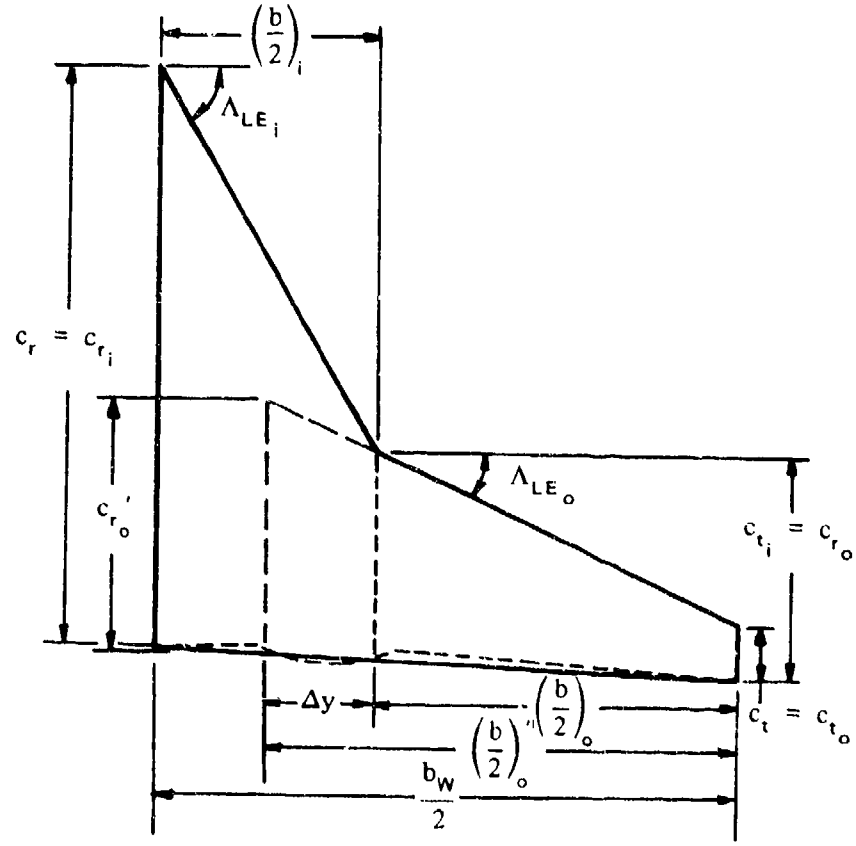
$$\frac{dC_m}{dC_L} = \left(\frac{dC_m}{dC_L}\right)_{theory} \left[\frac{dC_m/dC_L}{(dC_m/dC_L)_{theory}}\right] \qquad \text{(Equation 4.1.4.2-c)}$$

$$= (-0.027)(0.935)$$

$$= -0.0252 \qquad \left(\text{based on } S_W c_r, \text{ about } \frac{c_r}{2}\right)$$

2. Non-Straight-Tapered Wings

Given: The cranked wing of Reference 22.



Total-Wing Characteristics:

$A_W = 5.194$ $\quad \lambda_W = 0.090$ $\quad \Lambda_{LE_i} = 60^o$ $\quad \Lambda_{LE_o} = 25^o$

$\eta_B = 0.380$ $\quad c_{r_W} = 50.10$ in. $\quad \frac{b_W}{2} = 50.40$ in.

Constructed Inboard-Panel Characteristics:

$A_i = 1.14$ $\lambda_i = 0.339$ $\Lambda_{LE_i} = 60^o$ $\Lambda_{TE_i} = 1.75^o$

$\left(\frac{b}{2}\right)_i = 19.15$ in. $S_i = 1285$ sq in. $\left(\Lambda_{c/2}\right)_i = 40.9^o$

$c_{r_i} = 50.10$ in. $c_{t_i} = 16.98$ in.

Constructed Outboard-Panel Characteristics:

$A_o' = 6.37$ $\lambda_o' = 0.213$ $\left(\frac{b}{2}\right)_o' = 40.83$ in. $S_o' = 1047$ sq in.

$c_{r_o}' = 21.15$ in. $c_{t_o} = 4.50$ in $\Lambda_{LE_o} = 25^o$ $\Lambda_{TE_o} = 1.75^o$

$\left(\Lambda_{c/2}\right)_o = 14.7^o$ $\Delta y = 9.576$ in.

Additional Characteristics:

$M = 0.13$; $\beta = 0.991$ $\kappa = 1.0$ (assumed)

Compute:

$\left(C_{L_\alpha}\right)_i$ (Section 4.1.3.2)

$$\frac{A_i}{\kappa}\left[\beta^2 + \tan^2\left(\Lambda_{c/2}\right)_i\right]^{1/2} = \frac{1.14}{1.0}\left[(0.991)^2 + (0.8662)^2\right]^{1/2} = 1.50$$

$\left(\frac{C_{L_\alpha}}{A}\right)_i = 1.39$ per rad (Figure 4.1.3.2-49)

$$\left(C_{L_\alpha}\right)_i = \left(\frac{C_{L_\alpha}}{A}\right)_i A_i = 1.39\ (1.14) = 1.58 \text{ per rad}$$

$\left(\frac{x_{a.c.}}{c_r}\right)_i$

$\left(A \tan \Lambda_{LE}\right)_i = (1.14)(1.7321) = 1.975$; $\frac{\beta}{\tan \Lambda_{LE_i}} = \frac{0.991}{1.7321} = 0.572$

$\left(\frac{x_{a.c.}}{c_r}\right)_i = 0.452$ (Figures 4.1.4.2-26a through -26e, interpolated)

$\left(C_{L_a}\right)_o'$ (Section 4.1.3.2)

$$\frac{A_o'}{\kappa}\left[\beta^2 + \tan^2(\Lambda_{c/2})_o\right]^{1/2} = \frac{6.37}{1.0}\left[(0.991)^2 + (0.2623)^2\right]^{1/2} = 6.53$$

$$\left(\frac{C_{L_a}}{A}\right)_o = 0.715 \text{ per rad (Figure 4.1.3.2-49)}$$

$$\left(C_{L_a}\right)_o' = \left(\frac{C_{L_a}}{A}\right)_o A_o' = (0.715)(6.37) = 4.55 \text{ per rad}$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_o$$

$$\left(A \tan \Lambda_{LE}\right)_o' = (6.37)(0.4663) = 2.97; \quad \frac{\tan \Lambda_{LE_o}}{\beta} = \frac{0.4663}{0.991} = 0.471$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_o' = 0.543 \quad \text{(Figures 4.1.4.2-26a through -26e, interpolated)}$$

$$\frac{\left(x_{a.c.}\right)_o'}{c_{r_i}} = \left(\frac{x_{a.c.}}{c_r}\right)_o' \left(\frac{c_{r_o}'}{c_{r_i}}\right) - \frac{\Delta y}{c_{r_i}} \tan \Lambda_{LE_o} + \frac{b_i}{2c_{r_i}} \tan \Lambda_{LE_i} \quad \text{(Equation 4.1.4.2-d)}$$

$$= (0.543)\left(\frac{21.15}{50.10}\right) - \frac{9.576}{50.10}(0.4663) + \frac{19.15}{50.10}(1.7321)$$

$$= 0.802$$

Solution:

$$\frac{x_{a.c.}}{c_r} = \frac{\left(C_{L_a}\right)_i S_i \left(\frac{x_{a.c.}}{c_r}\right)_i + \left(C_{L_a}\right)_o' S_o' \frac{\left(x_{a.c.}\right)_o'}{c_{r_i}}}{\left(C_{L_a}\right)_i S_i + \left(C_{L_a}\right)_o' S_o'} \quad \text{(Equation 4.1.4.2-e)}$$

$$= \frac{1.58\,(1285)\,(0.452) + 4.55\,(1047)\,(0.802)}{1.58\,(1285) + 4.55\,(1047)}$$

$$= 0.697$$

The calculated value compares with a test value of 0.688 from Reference 22.

B. TRANSONIC

Rather than producing linear results as in other speed regimes, application of small-perturbation theory to the transonic regime yields a nonlinear differential equation. This means that at transonic Mach numbers it is not possible to evaluate separately the effects of thickness, camber, and angle of attack, and then to add the individual solutions to obtain the total wing lift and pitching moment. The contributions of each of the above parameters are interrelated, and the wing must be treated as a unit. Theoretical solutions in the transonic speed range are available for only a few specific planforms. Most of the available information on the transonic characteristics of wings is in the form of wind-tunnel test data. As discussed in detail in Section 4.1.3.2, transonic test data are subject to wind-tunnel wall interference effects and must be used with caution.

The use of similarity parameters reduces to a minimum the number of charts required to present test data. Similarity parameters are derived from theoretical considerations and are subject to the limitations of the theory from which they are derived. Although the form of the parameters may be changed by rearranging the variables, the minimum number of parameters for a given theory does not change.

From the nonlinear equations describing transonic flow, it can be shown (Reference 9) that the minimum number of parameters necessary to present complete information in the transonic speed regime is one greater than the number of parameters necessary for the linear theories of both the subsonic and supersonic speed ranges. This means that the number of charts required to present information at transonic speeds is one order of magnitude larger than the number required for either of the other speed ranges.

Only a limited amount of work has been done in organizing transonic test data by means of similarity parameters. The most extensive effort along these lines is given in Reference 10. In this reference, test data from 50 rectangular wings of differing aspect ratio, airfoil thickness, and airfoil section are correlated by means of transonic similarity parameters, with a high degree of success.

For the Datcom, the charts of Reference 10 for rectangular, symmetrical wings at zero angle of attack are adopted directly. Charts for straight-tapered wings of other planform shapes are developed by applying transonic similarity parameters to the experimental data of References 11 through 15. The combined charts for all planforms are presented as Figures 4.1.4.2-30a through 4.1.4.2-30d.

These transonic charts are applicable only to uncambered straight-tapered wings with symmetric airfoil sections at low angles of attack. Wings with cambered airfoils, double-wedge airfoils, and airfoils with blunt trailing edges show different transonic moment and lift characteristics.

Wings with thickness ratios greater than about 7 percent are subject to shock-induced separation effects of significant magnitude. These effects are not accounted for by small-perturbation theory and thus cannot be handled by the similarity parameters of this section. Since there is great similarity between the effects of shock-induced separation on moment and on lift, the treatment of separation-induced moment characteristics in this section is based on the procedure of Section 4.1.3.2 for transonic lift.

DATCOM METHOD

The charts of the Datcom are presented in terms of the transonic similarity parameters of Reference 10. The similarity parameters used for velocity and aspect ratio, respectively, are

$$\bar{V} = \frac{\beta^2}{(t/c)^{2/3}} \text{ and } \bar{A} = A(t/c)^{1/3}$$

The corresponding parameter for angle of attack is

$$\bar{\alpha} = \frac{\alpha}{(t/c)}$$

However, since all of the transonic charts of this section are for low angles of attack such that $\bar{\alpha} \approx 0$, this last parameter does not enter into the calculations.

Figures 4.1.4.2-30a through 4.1.4.2-30d give the a.c. location for symmetrical straight-tapered wings of arbitrary sweep angle, taper ratio, and thickness ratio. For rectangular wings a more thorough presentation of a.c. location as a function of the velocity parameter $\bar{V}$ is given in Figure 4.1.4.2-30d.

The following steps outline the calculation procedure:

Step 1. Determine the aspect-ratio similarity parameter $\bar{A}$.

Step 2. For the appropriate values of λ, A tan Λ_{LE}, and $\bar{A}$, read $\frac{x_{a.c.}}{c_r}$ from Figures 4.1.4.2-30a through 4.1.4.2-30d for values $\bar{V} = \frac{\beta^2}{(t/c)^{2/3}} = -2, -1, 0, +1$. (Cross plots must be made between taper ratios of 0.5 and 1.0.)

Step 3. Determine the Mach numbers corresponding to $\bar{V} = -2, -1, 0, +1$.

Step 4. Calculate $\frac{x_{a.c.}}{c_r}$ for M = 0.6 and M = 1.4 as outlined in the straight-tapered-wing methods of Paragraphs A and C, respectively, of this section.

Step 5. The complete transonic a.c.-location curve can now be constructed by fairing a curve through the points obtained by means of Steps 1 through 4.* (See Sketch (c))

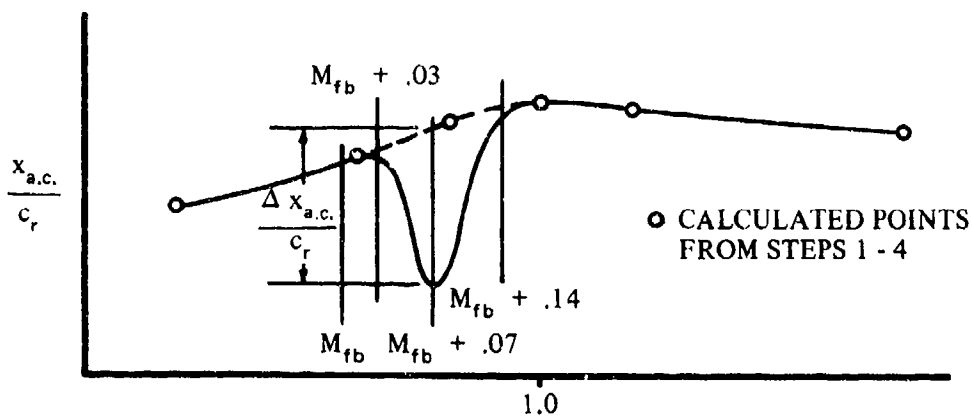
Step 6. The slope of the pitching-moment curve can now be calculated from the equation

$$C_{m_\alpha} = \left(n - \frac{x_{a.c.}}{c_r}\right) \frac{c_r}{\bar{c}} C_{L_\alpha} \qquad 4.1.4.2\text{-f}$$

where C_{L_α} is the lift-curve slope at transonic speeds obtained from Paragraph B of Section 4.1.3.2.

*If the wing under consideration has a thickness ratio greater than 7 percent, the additional Step 7 is required.

Step 7. Determine the incremental a.c. location accounting for separation effects $\frac{\Delta x_{a.c.}}{c_r}$ from Figure 4.1.4.2-33. This increment is applied at the Mach number at which the transonic lift-curve slope reaches its minimum value (M_{fb} + 0.07). The force-break Mach number M_{fb} is obtained during the course of calculating the transonic C_{L_α} values. Application of this a.c. increment and the required fairing technique are illustrated in Sketch (c).



SKETCH (c)

The above sketch represents the a.c. location at zero angle of attack. As the angle of attack is increased, the bucket in the curve near Mach 1 disappears and the shape is more like the dashed portions of Sketch (c).

Sample Problem

Given: The following straight-tapered wing:

$A = 4.0 \qquad \lambda = 0.68 \qquad \Lambda_{LE} = 46.32^o \qquad \Lambda_{c/2} = 43.6^o$

NACA 63A012 airfoil $\quad c_r/\bar{c} = 1.18 \qquad n = 1.09$

Compute:

$$\bar{A} = A\left(\frac{t}{c}\right)^{1/3} = (4.0)(0.493) = 1.972$$

$$A \tan \Lambda_{LE} = (4.0)(\tan 46.32^o) = 4.19$$

Determine $\frac{x_{a.c.}}{c_r}$ for $\bar{V} = -2, -1, 0,$ and $1,$ and the Mach numbers corresponding to $\bar{V}$

$$\bar{V} = \frac{\beta^2}{(t/c)^{2/3}} = \frac{\beta^2}{(0.2433)}; \qquad M = \sqrt{1 + 0.2433\,\bar{V}}$$

$\bar{V}$	M_1 $\sqrt{1 + 0.2433\,\bar{V}}$	$\frac{x_{a.c.}}{c_r}$ Fig. 4.1.4.2-30
-2	.716	1.020
-1	.870	1.055
0	1.000	1.055
1	1.115	1.080

Determine $\frac{x_{a.c.}}{c_r}$ at M = 0.6 and 1.40

$$M = 0.6;\ \beta = 0.80;\ \frac{\beta}{\tan \Lambda_{L.E}} = \frac{0.80}{\tan 46.32^o} = 0.764$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_{M\,=\,0.6} = 1.05 \qquad \text{(Figures 4.1.4.2-26d through -26f, interpolated)}$$

$$M = 1.40;\ \beta = 0.98;\ \frac{\beta}{\tan \Lambda_{LE}} = \frac{0.98}{\tan 46.32^o} = 0.936$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_{M\,=\,1.40} = 1.205 \qquad \text{(Figures 4.1.4.2-26d through -26f, interpolated)}$$

Since (t/c) $>$ 0.07, step 7 of the Datcom method is required.

$\left(M_{fb}\right)\Lambda = 0 = 0.82$ (Figure 4.1.3.2-53a)

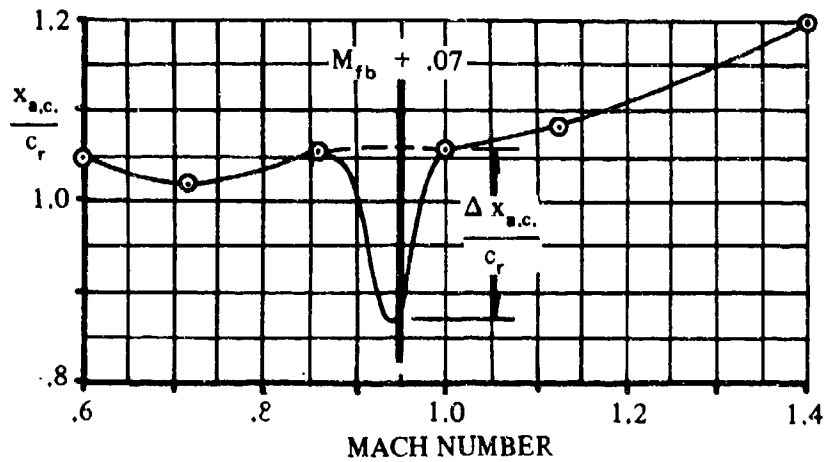
$\left(M_{fb}\right)\Lambda = 0.88$ (Figure 4.1.3.2-53b)

M_{fb} is obtained during the course of calculating C_{L_α}. It is shown here, since the calculations for C_{L_α} are not given.

$$A \cos^2 \Lambda_{c/2} = (4.0)(\cos 43.6)^2 = 2.10$$

$\frac{\Delta x_{a.c.}}{c_r} = -0.19$ (Figure 4.1.4.2-33). This correction is applied at $M_{fb} + 0.07 = 0.95$

Construct the transonic a.c. curve using Sketch (c) as a guide.



Determine C_{L_a} from Paragraph B, Section 4.1.3.2 (see calculation table below).

Solution:

$$C_{m_a} = \left(n - \frac{x_{a.c.}}{c_r}\right)\frac{c_r}{\bar{c}}\ C_{L_a} \quad \text{(Equation 4.1.4.2-f)}$$

$$= \left(1.09 - \frac{x_{a.c.}}{c_r}\right) 1.18\, C_{L_a}$$

C. SUPERSONIC

Methods are presented for determining the wing aerodynamic-center location of the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal wings)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

These three general categories of non-straight-tapered wings are illustrated in Sketch (a) of Section 4.1.3.2. Their wing-geometry parameters are presented in Section 2.2.2.

As is the case at subsonic speeds, the supersonic design charts also present information that is basically that of Reference 2. The effects of Mach number have been accounted for by means of the Prandtl-Glauert compressibility correction, and the resulting design charts are an extension of those used at subsonic speeds. The charts are directly applicable to straight-tapered wings. In treating non-straight-tapered wings, the wing is divided into two panels and the individual lift and aerodynamic-center location for each panel are used to establish the aerodynamic-center location for the composite wing.

The design charts are applicable only in the linear-lift range. Within this range the effects of camber, leading-edge radius, and trailing-edge angle are minor in regard to the aerodynamic-center characteristics.

Although wing profile thickness has little effect on the supersonic wing normal-force-curve slope at low angles of attack, provided the Mach lines do not lie near the wing leading edge (Sections 4.1.3.2 and 4.1.3.3), the situation regarding wing pitching moments is quite different. For unswept wings of high aspect ratio at supersonic speeds, the area influenced by the three-dimensional flow within the tip shock cones is relatively small compared to the large area between the tip shocks, where the flow is two-dimensional. Under these conditions the wing moment characteristics are closely related to the two-dimensional airfoil characteristics. In Section 4.1.2.2 it is shown that for airfoils the aerodynamic center is very much a function of thickness ratio. As a first approximation, the a.c. location for unswept wings at supersonic speeds may be taken as that of the corresponding two-dimensional section.

For swept wings the three-dimensional flow within the shock cones is much larger, and the wing cannot be treated as two-dimensional. Linear theory generally gives satisfactory results for these wings.

As the Mach lines approach the leading edges of wings at supersonic speeds, the lift may deviate considerably from linear-theory lift. These deviations (see Section 4.1.3.2, Paragraph C) are caused by the finite thickness of the wing leading edge, which forces the leading-edge shock to be located at a different position from that predicted by linear theory. For delta wings, at least, these effects on lift are not reflected in the pitching moments. This is perhaps due to the fact that linear theory predicts the same a.c. location for delta wings, whether the leading-edge shock is attached or

detached. For other wings, linear theory does predict minor changes in a.c. location when the leading-edge shock attaches. In general, however, it appears that the role of wing thickness in causing deviations from linear theory at the sonic-leading-edge condition is much less for moments than it is for lift.

DATCOM METHODS

Straight-Tapered Wings

The aerodynamic-center location of swept, straight-tapered wings at Mach numbers greater than 1.4 is obtained from Figures 4.1.4.2-26a through 4.1.4.2-26f. These charts give the a.c. location as a fraction of the wing root chord. For unswept wings, the method of Section 4.1.2.2 for two-dimensional sections in supersonic flow may be used.

Non-Straight-Tapered Wings

The method presented in Paragraph A for predicting the aerodynamic-center location of non-straight-tapered wings is also applicable at supersonic speeds. The normal-force-curve slopes of the constructed inboard and outboard panels are obtained from the straight-tapered-wing design charts of Paragraph C of Section 4.1.3.2 (Figures 4.1.3.2-56a through 4.1.3.2-56f). The a.c. locations of the constructed inboard and outboard panels, measured in root chords of the respective panels, are obtained from the supersonic portion of Figures 4.1.4.2-26a through 4.1.4.2-26f.

Equation 4.1.4.2-e expressed in terms of the normal-force-curve slope is

$$\frac{x_{a.c.}}{c_r} = \frac{\left(C_{N_\alpha}\right)_i S_i \left(\frac{x_{a.c.}}{c_r}\right)_i + \left(C_{N_\alpha}\right)_o' S_o' \frac{\left(x_{a.c.}\right)_o'}{c_{r_i}}}{\left(C_{N_\alpha}\right)_i S_i + \left(C_{N_\alpha}\right)' S_o'}$$

where $x_{a.c.}/c_r$ is the aerodynamic center of the non-straight-tapered wing, measured in wing root chords aft of the wing apex.

The limited availability of experimental data precludes the substantiation of this method for double-delta and cranked wings. No experimental wing-alone cranked-wing data are readily available for supersonic speeds. Test data for one wing-alone double-delta configuration are available (Reference 31). This method predicts the a.c. location for this wing to within about one percent of the test value.

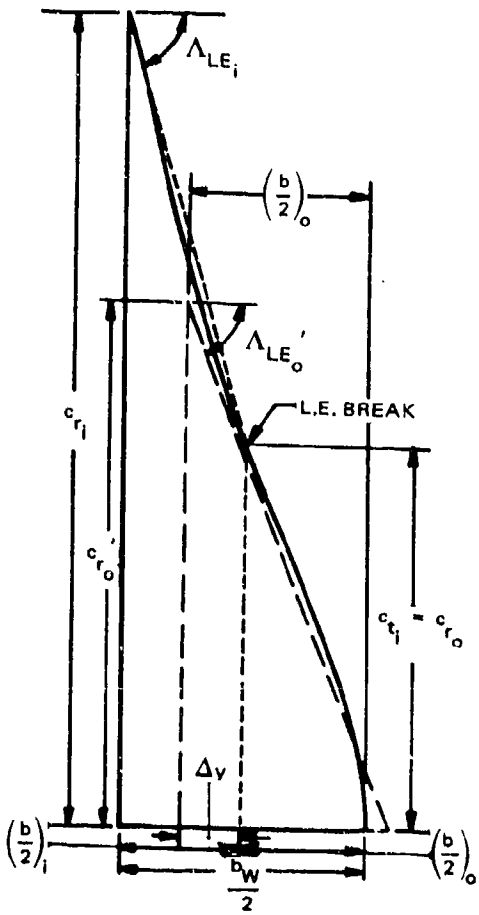
A comparison of test data for three curved-wing configurations with $x_{a.c.}/c_r$ calculated by this method is presented as Table 4.1.4.2-C (taken from Reference 8). One of the configurations is a wing-body combination, but the body is very small and the wing planform projection effectively blankets nearly all the body. All the wings investigated have straight trailing edges and one reflex curve in the leading edge. The Mach-number and lift-coefficient ranges of the data are:

$$1.02 \leqslant M \leqslant 2.60$$

$$0 \leqslant C_L \leqslant 0.10$$

Sample Problem

Given: The ogee wing-body configuration of Reference 29. Since the wing-planform projection blankets nearly all of the body, the combination is treated as a wing-alone configuration.



Total-Wing Characteristics:

$A_W = 1.20 \qquad \Lambda_{TE} = 0 \qquad c_{r_W} = 20.0$ in.

$\frac{b_W}{2} = 6.0$ in.

$t/c = 0.05$ (rhombic wing sections – free-stream direction)

Constructed Inboard-Panel Characteristics:

$A_i = 0.407 \qquad \lambda_i = 0.475 \qquad \left(\frac{b}{2}\right)_i = 3.0$ in.

$S_i = 88.5$ sq in. $\qquad c_{r_i} = 20.0$ in. $\qquad c_{t_i} = 9.50$ in.

$\Lambda_{LE_i} = 74.6^o$

Constructed Outboard-Panel Characteristics:

$A_o' = 1.57 \qquad \lambda_o' = 0 \qquad \left(\frac{b}{2}\right)_o' = 5.10$ in.

$S_o' = 66.3$ sq in. $\qquad c_{r_o}' = 13.0$ in. $\qquad \Lambda_{LE_o} = 68.6^o$

$\Delta y = 1.50$ in.

Additional Characteristics:

$M = 1.82; \ \beta = 1.52$

Compute:

$\left(C_{N_\alpha}\right)_i$ (Section 4.1.3.2)

$\left(A \tan \Lambda_{LE}\right)_i = (0.407)(\tan 74.6^o) = 1.477$

$\frac{\beta}{\tan \Lambda_{LE_i}} = \frac{1.52}{\tan 74.6^o} = 0.419$

$\left[\tan \Lambda_{LE} \left(C_{N_\alpha}\right)_{theory}\right]_i = 2.67$ per rad (Figures 4.1.3.2-56c through -56e, interpolated)

$\left[\left(C_{N_\alpha}\right)_{theory}\right]_i = \frac{2.67}{\tan 74.6^o} = 0.736$ per rad

$$\left[\frac{C_{N_\alpha}}{(C_{N\alpha\ \text{theory}})}\right]_i$$

$$\delta_\perp = \frac{\text{semiwedge angle}}{\cos \Lambda_{LE}} = \frac{\frac{1}{2}\left(\frac{0.05}{0.5}\right)}{\cos 74.6^o} (57.3) = 10.8^o$$

$$\Delta y_\perp = 5.85 \tan \delta_\perp = 5.85 \tan 10.8^o = 1.116$$

$$\left[\frac{C_{N_\alpha}}{(C_{N_\alpha})_{\text{theory}}}\right]_i = 1.0 \quad \text{(Figure 4.1.3.2-60)}$$

$$(C_{N_\alpha})_i = \left[\frac{C_{N_\alpha}}{(C_{N_\alpha})_{\text{theory}}}\right]_i \left[(C_{N_\alpha})_{\text{theory}}\right]_i = (1.0)(0.736) = 0.736 \text{ per rad}$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_i$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_i = 0.465 \quad \text{(Figures 4.1.4.2-26a through -26e, interpolated)}$$

$(C_{N_\alpha})_o'$ (Section 4.1.3.2)

$$(A \tan \Lambda_{LE})_o' = 1.57 (\tan 68.6^o) = 4.01$$

$$\frac{\beta}{\tan \Lambda_{LE_o}} = \frac{1.52}{\tan 68.6^o} = 0.596$$

$$\left[\tan \Lambda_{LE} \ (C_{N_\alpha})_{\text{theory}}\right]_o' = 4.92 \text{ per rad} \quad \text{(Figure 4.1.3.2-56a)}$$

$$\left[(C_{N_\alpha})_{\text{theory}}\right]_o' = \frac{4.92}{\tan 68.6^o} = 1.93 \text{ per rad}$$

$$\left[\frac{C_{N_\alpha}}{(C_{N_\alpha})_{\text{theory}}}\right]_o'$$

$$\delta_\perp = \frac{\text{semiwedge angle}}{\cos \Lambda_{LE}} = \frac{\frac{1}{2}\left(\frac{0.05}{0.5}\right)}{\cos 68.6^o} (57.3) = 7.85^o$$

$$\Delta y_{\perp} = 5.85 \tan \delta_{\perp} = 5.85 \tan 7.85^{o} = 0.807$$

$$\left[\frac{C_{N_\alpha}}{(C_{N_\alpha})_{theory}}\right]_o' = 0.965 \quad \text{(Figure 4.1.3.2-60)}$$

$$(C_{N_\alpha})_o' = \left[\frac{C_{N_\alpha}}{(C_{N_\alpha})_{theory}}\right]_o' \left[(C_{N_\alpha})_{theory}\right]_o' = 0.965\,(1.93) = 1.86 \text{ per rad}$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_o$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_o = 0.670 \text{ (Figure 4.1.4.2-26a)}$$

$$\frac{(x_{a.c.})_o'}{c_{r_i}} = \left(\frac{x_{a.c.}}{c_r}\right)_o' \left(\frac{c_{r_o}'}{c_{r_i}}\right) - \frac{\Delta y}{c_{r_i}} \tan \Lambda_{LE_o} + \frac{b_l}{2c_{r_i}} \tan \Lambda_{LE_i} \quad \text{(Equation 4.1.4.2-d)}$$

$$= (0.670)\ \frac{13.0}{20.0} - \frac{1.50}{20.0}\ (2.552) + \frac{3.0}{20.0}\ (3.630)$$

$$= 0.789$$

Solution:

$$\frac{x_{a.c.}}{c_r} = \frac{(C_{N_\alpha})_i\ S_i \left(\frac{x_{a.c.}}{c_r}\right)_i + (C_{N_\alpha})_o'\ S_o'\ \frac{(x_{a.c.})_o'}{c_{r_i}}}{(C_{N_\alpha})_i\ S_i + (C_{N_\alpha})_o'\ S_o'} \quad \text{(Equation 4.1.4.2-e)}$$

$$= \frac{(0.736)\,(88.5)\,(0.465) + (1.86)(66.3)\,(0.789)}{(0.736)\,(88.5) + (1.86)\,(66.3)}$$

$$= 0.677$$

The calculated value compares with a test value of 0.693 from Reference 29.

D. HYPERSONIC

The aerodynamic center of flat-plate straight-tapered wings approaches the area-centroid location as the Mach number becomes large. However, the interrelated effects of viscosity, heat transfer, and detached shock waves due to blunt leading edges cause deviations of the aerodynamic center from the theoretical values. The magnitude of these effects has not been thoroughly evaluated. The hypersonic method of this section is based on linear theory, which gives the location of the aerodynamic center at the area centroid for high Mach numbers.

DATCOM METHOD

The supersonic portions of Figures 4.1.4.2-26a through 4.1.4.2-26f give the a.c. location of straight-tapered wings at zero angle of attack. These charts are derived from linear theory in this region.

4.1.4.3 WING PITCHING MOMENT IN THE NONLINEAR ANGLE-OF-ATTACK RANGE

Methods are presented herein for estimating the wing pitching-moment coefficient in the nonlinear angle-of-attack region. In the subsonic speed regime methods are presented for both straight-tapered and non-straight-tapered wings. No generalized methods are presented in the transonic or supersonic speed regimes. However, at supersonic speeds a discussion of pitching-moment characteristics is given for rectangular and triangular wings.

A. SUBSONIC

At subsonic speeds empirical methods are presented for predicting the pitching-moment characteristics of the following two classes of wing planforms:

Straight-Tapered Low-Aspect-Ratio Wings

Non-Straight-Tapered Wings (double-delta wings)

No method is presented for evaluating straight-tapered wings of high aspect ratios.* For high-aspect-ratio wings with low sweepback, the center-of-pressure location beyond the linear-lift range moves aft, tending toward the wing midchord at full stall. The magnitude and rate of this trend are variable, depending largely on the particular airfoil section. Insufficient data are available to predict, even from a qualitative standpoint, the pitching-moment characteristics of moderately swept high-aspect-ratio wings beyond the linear-lift range.

For thin, low-aspect-ratio wings there exist areas of flow separation, even at moderate angles of attack. Consequently, for these wings the pitching-moment curve has a tendency to become nonlinear at moderate angles of attack.

Two methods are presented for low-aspect-ratio straight-tapered wings. Method 1 is general and is applicable to most low-aspect-ratio planforms. Method 2 is more restrictive in that it is applicable only at $M = 0.2$ for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with large thickness ratios; i.e., $0.10 \leq t/c \leq 0.30$. The unique feature of Method 2 is its consideration of the vortex-induced lift and its effect upon the pitching moment.

DATCOM METHODS

Straight-Tapered Wing

Method 1

The following empirical method is applicable to straight-tapered wings that satisfy the following relationship:

$$A \leq \frac{6}{(C_1 + 1)\cos \Lambda_{LE}}$$

*For the purposes of this section, high aspect-ratio wings are those for which $A > \frac{6}{(C_1 + 1)\cos \Lambda_{LE}}$, where C_1 is the empirical taper-ratio factor from Section 4.1.3.4.

where

A is the wing aspect ratio.

C_l is the empirical taper-ratio factor obtained from Figure 4.1.3.4-24b as a function of wing taper ratio.

Λ_{LE} is the sweepback angle of the wing leading edge.

The wing pitching-moment coefficient, based on the product of the wing area and wing MAC $S_W \bar{c}_W$, referred to the desired center-of-gravity location, is given by

$$C_m = \left(n - \frac{x_{c.p.}}{c_r} \right) \frac{c_r}{\bar{c}} C_N \qquad 4.1.4.3\text{-a}$$

where

n is the chordwise distance in root chords from the wing apex to the desired center-of-gravity location, positive aft.

$\frac{c_r}{\bar{c}}$ is the ratio of the wing root chord to the wing mean aerodynamic chord.

C_N is the wing normal-force coefficient, based on the wing area. This parameter should be obtained from test data if available, or by using Equation 4.1.3-a, i.e.,

$$C_N = C_L \cos\alpha + C_D \sin\alpha$$

where

C_L is the wing lift coefficient from test data or from the methods of Sections 4.1.3.1, 4.1.3.2, and 4.1.3.3.

C_D is the wing drag coefficient from test data or from Sections 4.1.5.1 and 4.1.5.2.

α is the wing angle of attack.

It should be noted that in the absence of wing drag data, the normal force may be approximated (see Section 4.1.3.3) by

$$C_N = \frac{C_L}{\cos\alpha}$$

$\frac{x_{c.p.}}{c_r}$ is the wing center-of-pressure location, in wing root chords, measured positive aft from the wing apex. Because of the various relationships used to calculate $\frac{x_{c.p.}}{c_r}$ for angles of attack between 0 and 90°, the following step-by-step procedure is given to facilitate the calculation of $\frac{x_{c.p.}}{c_r}$ versus angle of attack.

Step 1. Calculate the center-of-pressure location at zero lift. The center-of-pressure location at zero lift may be approximated as the aerodynamic center of a wing with a symmetrical airfoil section, at zero angle of attack, which is given in Section 4.1.4.2 as a function of wing planform parameters.

Step 2. Calculate the center-of-pressure location at maximum lift by

$$\left(\frac{x_{c.p.}}{c_r}\right)_{C_{L_{max}}} = \left(\frac{x_{c.p.}}{c_r}\right)_1 + \Delta\left(\frac{x_{c.p.}}{c_r}\right)_2 \qquad 4.1.4.3\text{-b}$$

where

$\left(\frac{x_{c.p.}}{c_r}\right)_1$ is obtained from Figure 4.1.4.3-21a as a function of Δy, the airfoil section leading-edge sharpness parameter. The value of Δy can be obtained from Figure 2.2.1-8.

$\Delta\left(\frac{x_{c.p.}}{c_r}\right)_2$ is obtained from Figures 4.1.4.3-21b and -22a as a function of wing taper ratio, aspect ratio, and leading-edge sweepback.

No specific Mach-number correction is included, because the experimental data show only small and inconsistent shifts up to $M \approx 0.6$.

Caution must be exercised when applying the method of this section to wings having large values of $(C_l + 1) A \cos \Lambda_{LE}$. Configurations of this type show large forward shifts in center-of-pressure location with increasing lift coefficient. This forward shift is related to flow separation and local loss of lift aft of the area centroid. In situations where the forward shift in center of pressure takes place over a small range of lift coefficients, the phenomenon is known as pitch-up. Empirical charts have been developed to define approximate boundaries dividing configurations that show pitch-up from those that do not. One such chart is presented in Figure 4.1.4.3-25.

It is important to recognize that the pitch-up characteristics for any given wing can be strongly modified by wing twist and/or wing-leading-edge devices. An extensive summary of information on pitch-up control devices is given in Reference 1.

Because of their dependence on separation effects, pitch-up characteristics are also sensitive to Reynolds number. Lowering the Reynolds number aggravates pitch-up tendencies, and raising the Reynolds number suppresses them.

The charts for low-aspect-ratio wings apply to untwisted symmetrical-section wings at Reynolds numbers near 6×10^6, based on the mean aerodynamic chord.

Step 3. Calculate the variation of center-of-pressure location between $\alpha = 0$ and $\alpha = \tan^{-1}\left(\frac{\tan \alpha_{C_{L_{max}}}}{0.6}\right)$

a. Determine the stability index from Figure 4.1.4.3-22b as a function of the wing taper ratio, aspect ratio, and leading-edge sweepback.

b. Determine the aspect-ratio index from Figure 4.1.4.3-24a as a function of wing taper ratio, aspect ratio, and leading-edge sweepback.

c. Determine the values of $\Delta\left(\frac{x_{c.p.}}{c_r}\right)_3$ from Figure 4.1.4.3-23a or -23b as a function of the stability index and the ratio of $\frac{\tan\alpha}{\tan\alpha_{C_{L_{max}}}}$ or $\frac{\tan\alpha_{C_{L_{max}}}}{\tan\alpha}$, respectively. (The value of $\Delta\left(\frac{x_{c.p.}}{c_r}\right)_3$ at $\frac{\tan\alpha}{\tan\alpha_{C_{L_{max}}}} = 1$ is zero.)

d. Determine the values of $\Delta\left(\frac{x_{c.p.}}{c_r}\right)_4$ from Figure 4.1.4.3-24b as a function of the aspect-ratio index and the ratio of $\frac{\tan\alpha_{C_{L_{max}}}}{\tan\alpha}$ or $\frac{\tan\alpha}{\tan\alpha_{C_{L_{max}}}}$. (The value of $\Delta\left(\frac{x_{c.p.}}{c_r}\right)_4$ at $\frac{\tan\alpha}{\tan\alpha_{C_{L_{max}}}} = 1$ is zero.)

e. Determine the value of $\left(\frac{x_{c.p.}}{c_r}\right)_{ref}$ by

$$\left(\frac{x_{c.p.}}{c_r}\right)_{ref} = \frac{\left(\frac{x_{c.p.}}{c_r}\right)_{C_{L_{max}}}}{\sin\alpha_{C_{L_{max}}}} - \left(\frac{x_{c.p.}}{c_r}\right)_{C_L=0} \cot\alpha_{C_{L_{max}}} \qquad 4.1.4.3\text{-c}$$

where

$\left(\frac{x_{c.p.}}{c_r}\right)_{C_{L_{max}}}$ is obtained above in Step 2.

$\alpha_{C_{L_{max}}}$ is the angle of attack at maximum lift obtained from Section 4.1.3.4.

$\left(\frac{x_{c.p.}}{c_r}\right)_{C_L=0}$ is the zero-lift center-of-pressure location from Step 1 above.

f. Using the above parameters determine the center-of-pressure location by

$$\frac{x_{c.p.}}{c_r} = \left(\frac{x_{c.p.}}{c_r}\right)_{C_L=0} \cos\alpha + \left[\left(\frac{x_{c.p.}}{c_r}\right)_{ref} + \Delta\left(\frac{x_{c.p.}}{c_r}\right)_3 + \Delta\left(\frac{x_{c.p.}}{c_r}\right)_4\right] \sin\alpha \quad 4.1.4.3\text{-d}$$

Step 4. **Calculate the center-of-pressure location at an angle of attack of 90°. This point is at the area centroid and is found by**

$$\frac{x_{c.p.}}{c_r} = \frac{1}{3}\left(\lambda + \sigma + \frac{1 + \sigma\lambda}{1 + \lambda}\right) \quad 4.1.4.3\text{-e}$$

where

$$\sigma = \frac{1}{4} A (1 + \lambda) \tan \Lambda_{LE} \quad 4.1.4.3\text{-f}$$

where

A is the wing aspect ratio.

λ is the wing taper ratio.

Λ_{LE} is the sweepback angle of the wing leading edge.

Step 5. Calculate the center-of-pressure location between $\alpha = \tan^{-1}\left(\frac{\tan\alpha_{C_{L_{max}}}}{0.6}\right)$ and $\alpha = 90^\circ$ by assuming a linear variation of $\frac{x_{c.p.}}{c_r}$. (The center-of-pressure locations corresponding to $\alpha = \tan^{-1}\left(\frac{\tan\alpha_{C_{L_{max}}}}{0.6}\right)$ and $\alpha = 90^\circ$ are obtained from Steps 3 and 4, respectively.)

A comparison of test data with wing center-of-pressure locations computed by the use of the above procedure is shown in Table 4.1.4.3-A.

Method 2

This semiempirical method is taken from Reference 2, ignoring the small wing-planform nose-radius effects. The semiempirical method was developed by using the test results of Reference 2,

correlated with the theoretical predictions based on lifting-surface theory. Because of its semiempirical nature, the method should be restricted to M = 0.2 conditions for highly swept, constant-section, low-aspect-ratio, delta or clipped-delta configurations with the following geometric characteristics:

$$0.58 \leq A \leq 2.55$$

$$0 \leq \lambda \leq 0.3$$

$$63^{\circ} \leq \Lambda_{LE} \leq 80^{\circ}$$

$$0.10 \leq t/c \leq 0.30$$

$$\Lambda_{TE} = 0$$

For round-nosed-planform configurations the reader is referred to Reference 2, where three different planform-nose-radius models were tested. No incremental nose-planform effects are presented here because of their probable configuration dependence.

This method essentially accounts for the effect of leading-edge vortex-induced lift upon the pitching moment. For details regarding the leading-edge vortex-induced-lift increments, the reader is referred to Method 2 for straight-tapered planforms in Paragraph A of Section 4.1.3.2.

The nonlinear pitching-moment characteristics, taken about the midpoint of the wing root chord and based on the product of the wing area and root chord $S_w c_r$, for a given angle of attack, are estimated by

$$C_m = \left(\frac{dC_m}{dC_L}\right) C_{L_{basic}} + C_{m_0} + \Delta C_m \qquad 4.1.4.3\text{-g}$$

where

$\frac{dC_m}{dC_L}$ is the pitching-moment-curve slope from Method 2 of Paragraph A of Section 4.1.4.2, taken about the root-chord midpoint.

$C_{L_{basic}}$ is the basic wing lift excluding any leading-edge vortex-induced effects, at the particular angle of attack. This value must come from constructing the lift curve using Section 4.1.3.1 for the determination of α_0, and Method 2 of Paragraph A of Section 4.1.3.2 for the determination of $(C_{L_\alpha})_{basic}$.

C_{m_0} is the wing zero-lift pitching moment obtained from Method 2 of Paragraph A of Section 4.1.4.1.

ΔC_m is the pitching-moment increment about the root-chord midpoint due to the leading-edge vortex. This parameter is evaluated at the particular angle of attack using

$$\Delta C_m = \frac{-0.367\,\Delta C_L}{(1 + \cos^2 \Lambda_{LE})(1 + \lambda^2)\cos(\alpha + \bar{\theta})} \qquad 4.1.4.3\text{-h}$$

where

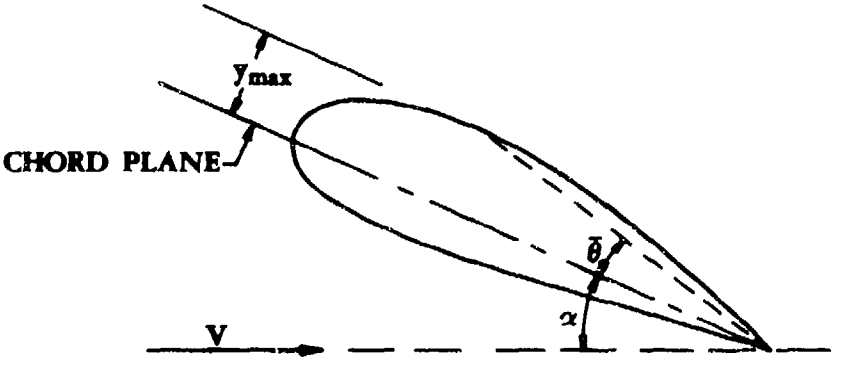
ΔC_L is the lift increment due to the leading-edge vortex at the particular angle of attack (see Sketch (b) in Section 4.1.3.2). This value is obtained using Method 2 of Section 4.1.3.2.

Λ_{LE} is the wing leading-edge sweep.

λ is the wing taper ratio.

α is the wing angle of attack.

$\bar{\theta}$ is the angle between the airfoil chord line and a line connecting the airfoil trailing edge to the airfoil maximum upper-surface ordinate (see Sketch (a)).



SKETCH (a)

No substantiation of this method is possible because of the lack of low-aspect-ratio test data having wing thickness ratios of $0.10 \leq t/c \leq 0.30$.

Non-Straight-Tapered Wings (Double Delta)

The empirical method (taken from Reference 3) presented herein is applicable only to double-delta wings. This method should be applied with caution because it is based on a limited amount of test data. The test data used in the formulation of the method were obtained for double-delta planforms having the following geometric limitations:

$$60^\circ \leq \Lambda_{LE_i} \leq 83^\circ$$

$$38^\circ \leq \Lambda_{LE_o} \leq 60^\circ$$

$$0.2 \leq \eta_B \leq 0.7$$

The majority of the test data used in the method formulation are wing-body test data, where the body effects have been ignored. The use of wing-body data can be justified because the data exhibit large values for the ratio of wing span to body diameter and because of the scarcity of wing-alone double-delta test data.

For a double-delta wing, the pitching-moment coefficient, based on the product of wing area and wing MAC, referred to the desired reference-center location, is given by

$$C_m = C_{m_0} + C_L \left(n - K_m \frac{x_{a.c.}}{c_r} \right) \frac{c_r}{\bar{c}} \qquad 4.1.4.3\text{-i}$$

where

C_{m_0} is the zero-lift wing pitching-moment coefficient obtained from test data on a similar configuration or from Section 4.1.4.1.

C_L is the wing lift coefficient obtained from test data or from Sections 4.1.3.1, 4.1.3.2 and 4.1.3.3.

n is the chordwise distance in root chords from the wing apex to the desired reference-center location, positive aft.

K_m is the empirical nonlinear pitching-moment factor, obtained from Figures 4.1.4.3-26a through -26f as a function of angle of attack, Mach number, and wing leading-edge sweepback.

$\frac{x_{a.c.}}{c_r}$ is the distance from the wing apex to the aerodynamic center measured in root chords, positive aft. This parameter is obtained from test data or from the double-delta-wing method of Section 4.1.4.2.

$\frac{c_r}{\bar{c}}$ is the ratio of the root chord to the wing mean aerodynamic chord.

No substantiation table of this method is presented, because all available test data were used in the method formulation. However, a sample problem is presented to illustrate the method.

Sample Problems

1. Method 1

Given: Conventional, straight-tapered wing of Reference 4.

$A = 3.0$	$\lambda = 0.143$	NACA 65A003 airfoil	
$\Lambda_{LE} = 51.3^o$	$M = 0.6$	$C_{L_{max}} = 0.94$	$\alpha_{C_{L_{max}}} = 22^o$
$\bar{c} = 0.240$ ft	$c_r = 0.353$ ft	$n = 0.572$	

α (deg)	C_L	C_D
0	0	0.006
8	0.48	0.070
12	0.68	0.145
14	0.76	0.192
16	0.82	0.237
18	0.88	0.300
20	0.92	0.340
22	0.94	0.385
28	0.88	0.475

The variations of C_L and C_D with α, $C_{L_{max}}$, and $\alpha_{C_{L_{max}}}$ have been taken from the test data of Reference 2 to facilitate the calculations.

Compute:

Determine if the straight-taper-wing method is applicable; i.e., if $A \leqslant \frac{6}{(C_1 + 1)\cos \Lambda_{LE}}$.

$C_1 = 0.36$ (Figure 4.1.3.4-24b)

$$A \leqslant \frac{6}{(1.36)(0.6252)}$$

$$\leqslant 7.06$$

The aspect ratio of this configuration is 3.0; therefore, the method is applicable to this particular configuration.

Determine the normal-force coefficient using Equation 4.1.3-a, i.e.,

$$C_N = C_L \cos \alpha + C_D \sin \alpha$$

α	C_L	$\cos \alpha$	C_D	$\sin \alpha$	C_N
0	0	1.0	0.006	0	0

Determine the center-of-pressure location at zero lift

$$A \tan \Lambda_{LE} = (3.0)(1.2482) = 3.7446$$

$$\beta = \sqrt{1 - M^2}$$

$$= \sqrt{1 - 0.36}$$

$$= 0.80$$

$$\frac{\beta}{\tan \Lambda_{LE}} = \frac{0.80}{1.2482} = 0.641$$

$$\left(\frac{x_{a.c.}}{c_r}\right)_{C_L=0} = 0.635 \quad \text{(Figure 4.1.4.2-26, interpolated)}$$

$$\left(\frac{x_{c.p.}}{c_r}\right)_{C_L=0} \cong 0.635$$

Determine the center-of-pressure location at maximum lift

$$\Delta y = 0.6 \quad \text{(Figure 2.2.1-8)}$$

$$\left(\frac{x_{c.p.}}{c_r}\right)_1 = 0.55 \quad \text{(Figure 4.1.4.3-21a)}$$

$$C_3 = 0.28 \quad \text{(Figure 4.1.4.3-21b)}$$

$$(C_3 + 1) A \tan \Lambda_{LE} = (1.28)(3.0)(1.2482) = 4.78$$

$$\Delta\left(\frac{x_{c.p.}}{c_r}\right)_2 = 0.045 \quad \text{(Figure 4.1.4.3-22a)}$$

$$\left(\frac{x_{c.p.}}{c_r}\right)_{C_{L_{max}}} = \left(\frac{x_{c.p.}}{c_r}\right)_1 + \Delta\left(\frac{x_{c.p.}}{c_r}\right)_2 \quad \text{(Equation 4.1.4.3-b)}$$

$$= 0.55 + 0.045$$

$$= 0.595$$

Determine the variation of the center-of-pressure location between $\alpha = 0$ and $\alpha = \tan^{-1}\left(\frac{\tan \alpha_{C_{L_{max}}}}{0.6}\right)$

$$\alpha = \tan^{-1}\left(\frac{\tan \alpha_{C_{L_{max}}}}{0.6}\right)$$

$$= \tan^{-1}\left(\frac{0.4040}{0.6}\right)$$

$$= 33.95^{o}$$

Stability Index = 1.2 (Figure 4.1.4.3-22b)

$A \cos \Lambda_{LE} = (3.0)(0.6252) = 1.8756$

Aspect-Ratio Index = 0.17 (Figure 4.1.4.3-24a)

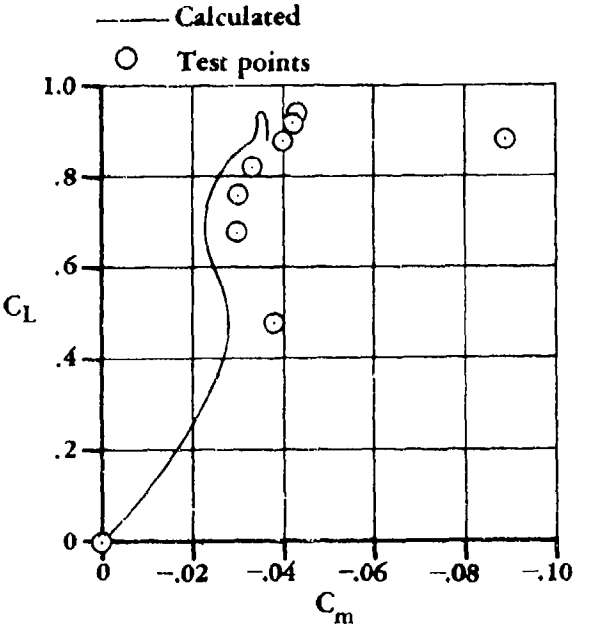
The calculated values are compared with test values from Reference 4 in Sketch (b).



SKETCH (b)

2. Method 2

Given: The following constant-section, low-aspect-ratio, clipped-delta configuration at $\alpha = 20^{\circ}$.

$A = 0.823$ $\quad \lambda = 0.18$ $\quad \Lambda_{LE} = 73.5^{\circ}$ $\quad$ NACA 2412 airfoil

$M = 0.2$ $\quad \theta = 0$ $\quad \bar{\theta} = 6.80^{\circ}$

$\left(C_{L_\alpha}\right)_{basic} = 0.0205$ per deg

$C_{L_{\alpha_{II}}} = 0.0272$ per deg

$C_{L_{\alpha_{III}}} = 0.0325$ per deg

$C_{L_{II}} = 0.222$

$C_{L_{III}} = 0.467$

} (Sample Problem 1 Method 2 Paragraph A Section 4.1.3.2)

$C_{m_0} = 0.0091$ (Sample Problem 2 Section 4.1.4.1)

$\frac{dC_m}{dC_L} = -0.0252$ (Sample Problem 1 Section 4.1.4.2)

Compute:

Determine α_0 using Section 4.1.3.1

$$(\alpha_0)_{\theta=0} = \alpha_i - \frac{c_{\ell_i}}{c_{\ell_\alpha}} \qquad \text{(Equation 4.1.3.1-a)}$$

$\alpha_i = 0.247$

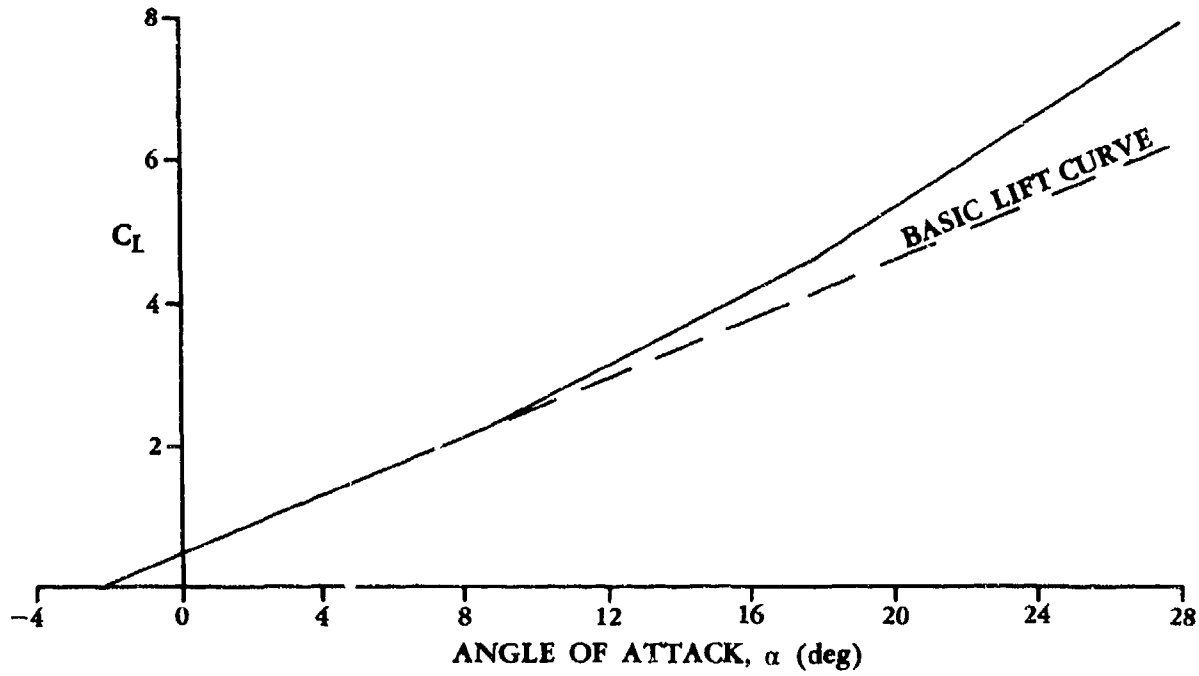
$c_{\ell_i} = 0.253$ } (Table 4.1.1-D)

$c_{\ell_\alpha} = 0.105$ per deg (Table 4.1.1-A)

$$(\alpha_0)_{\theta=0} = 0.247 - \frac{0.253}{0.105}$$

$$= -2.16^{\circ}$$

Now the complete lift curve can be constructed.



From the constructed lift curve

$\Delta C_L = 0.088$

$C_{L_{basic}} = 0.449$ } at $\alpha = 20^{\circ}$

$$\Delta C_m = \frac{-0.367\,\Delta C_L}{(1+\cos^2\Lambda_{LE})(1+\lambda^2)\cos(\alpha+\bar{\theta})} \qquad \text{(Equation 4.1.4.3-h)}$$

$$= \frac{(-0.367)(0.088)}{(1+0.0806)(1+0.0324)(0.8926)}$$

$$= -0.0324$$

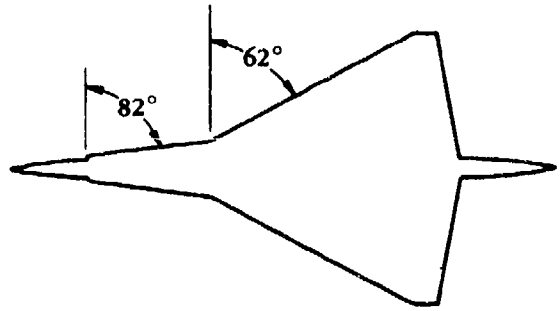
$$C_m = \left(\frac{dC_m}{dC_L}\right) C_{L_{basic}} + C_{m_0} + \Delta C_m \qquad \text{(Equation 4.1.4.3-g)}$$

$$= (-0.0243)(0.449) - 0.0091 - 0.0324$$

$$= -0.0524 \left(\text{based on } S_W c_r, \text{ about } \frac{c_r}{2}\right)$$

3. Double-Delta Wing

Given: The double-delta planform of Reference 5.



$A = 1.66$ $\quad \bar{c} = 21.68$ ft $\quad S = 505.9$ ft^2 $\quad M = 0.15$

$\left(C_{m_0}\right)_{WB} = 0.016$ $\quad \frac{x_{a.c.}}{\bar{c}} = 1.125$ $\quad n\left(\frac{c_r}{\bar{c}}\right) = 1.04$

α (deg)	C_L
0	−0.06
4	0.10
8	0.29
12	0.51
16	0.74
20	0.96

Compute:

$$\beta = \sqrt{1-M^2} = \sqrt{1-0.0225} = 0.989$$

$$\tan \Lambda_{LE_i} = \tan 82^o = 7.115$$

$$\frac{\beta}{\tan \Lambda_{LE_i}} = \frac{0.989}{7.115} = 0.139$$

Solution:

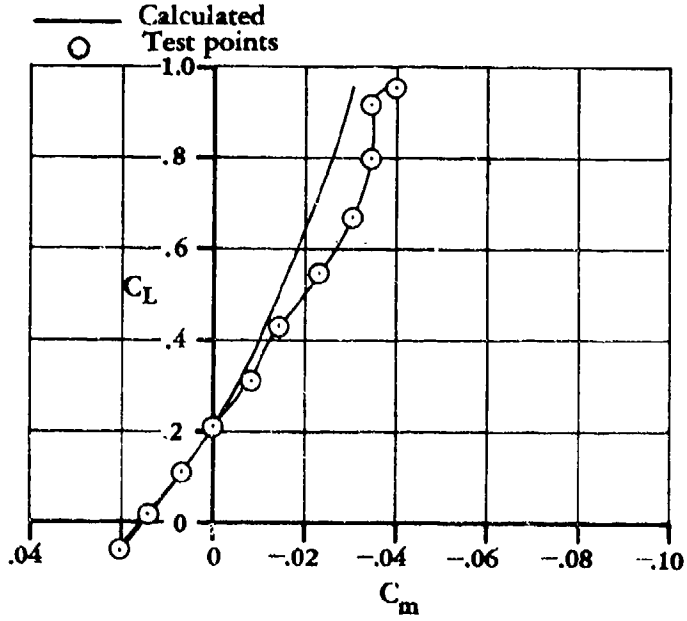
$$C_m = C_{m_0} + C_L \left(n - K_m \frac{x_{a.c.}}{c_r} \right) \frac{c_r}{\bar{c}} \qquad \text{(Equation 4.1.4.3-i)}$$

$$= C_{m_0} + C_L \left(n \frac{c_r}{\bar{c}} - K_m \frac{x_{a.c.}}{\bar{c}} \right)$$

$$= 0.016 + C_L (1.04 - 1.125 K_m)$$

α (deg)	K_m (Figures 4.1.4.3-26a through -26f)	C_m
0	1.0	0.021
4	0.995	0.008
8	0.985	−0.004
12	0.974	−0.013
16	0.971	−0.023
20	0.967	−0.030

The calculated values are compared with test values from Reference 5 in Sketch (c).



SKETCH (c)

B. TRANSONIC

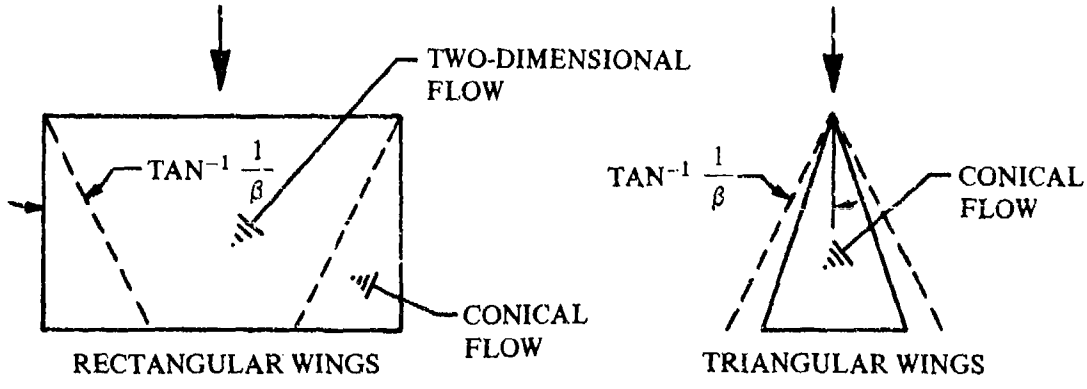
No generalized handbook method for estimating transonic values of the wing pitching-moment coefficient in the nonlinear angle-of-attack region is available in the literature. For double-delta planforms it is suggested that the method presented in Paragraph A of this section for double-delta planforms be applied with caution.

C. SUPERSONIC

No general method exists for predicting the supersonic pitching moments for wings at high angles of attack. For this reason no charts on this subject are presented in this section. However, a discussion of two particular types of configuration may provide some guides. The two configurations discussed are rectangular and triangular planforms.

Rectangular Wings

For rectangular wings in supersonic flow at low angles of attack there are two principal flow regimes – flow within the influence of the tip shock waves and flow at the center section. Flow within the influence of the tip shock waves is essentially conical in nature, and flow at the wing center section is two dimensional.



For the wing center section, then, two-dimensional pitching-moment characteristics apply. These are summarized in Section 4.1.2.2.

The effect of the tip influence on the three-dimensional wing is to force the center-of-pressure location forward.

The pitching-moment characteristics of rectangular wings in supersonic flow may be summarized as follows:

1. At low angles of attack the center-of-pressure location moves aft with increasing angle of attack, according to two-dimensional theory.

2. For situations where the tip influence is large compared to that of the two-dimensional region, the center-of-pressure location moves forward with increasing angle of attack. Trailing-edge separation on the wing center section also produces this effect.

3. For angles of attack beyond that at which the wing leading-edge shock detaches, the center-of-pressure location moves aft with increasing angle of attack. At an angle of attack of 90^{o} the wing center-of-pressure location is at the area centroid.

These variations of the center-of-pressure location with angle of attack are illustrated experimentally in the data of Reference 13.

Triangular Wings

For triangular wings the flow is conical over the entire wing. Two conditions apply -- subsonic leading edges and supersonic leading edges.

Triangular Wing with Subsonic Leading Edges

When the triangular wing has leading edges swept well within the Mach cone, slender-body theory applies. Slender-body theory makes no distinction between subsonic and supersonic speeds; therefore, the supersonic triangular-wing characteristics should be very similar to the subsonic triangular-wing characteristics. This is, in fact, the case and supersonic triangular wings with subsonic leading edges show a slight forward shift in center-of-pressure location with angle of attack that is remarkably similar to the subsonic shift. An illustration of this similarity is provided by a comparison of the supersonic data of Reference 14 with calculated subsonic characteristics of the same wing.

Triangular Wings with Supersonic Leading Edges

For triangular wings with supersonic leading edges, the center-of-pressure location changes very little with angle of attack. This is to be expected, since the aerodynamic-center location at zero angle of attack is at the area centroid, which is also the center-of-pressure location at an angle of attack of 90 degrees. Because shock waves separate from the leading edges of triangular wings at relatively low angles of attack (a result of sweep effects; see Section 4.1.3.3), the center of pressure will never be far from the area centroid. Reference 15 gives the center-of-pressure variation of a delta wing with supersonic leading edges.

4.1.5 WING DRAG

4.1.5.1 WING ZERO-LIFT DRAG

The total zero-lift drag or "profile" drag of a wing is usually considered to be composed of two parts, skin-friction drag and pressure drag. This division of drag is applicable in all speed regimes except the free-molecular-flow regime, where the normal concept of skin friction does not apply.

Skin Friction

Skin-friction drag is caused by shearing stresses within the thin layer of retarded air on the surface of the body known as the boundary layer. The boundary layer arises from the resistance of the viscous fluid to the motion of the body passing through it. Friction drag is extremely important, since it accounts for most of the drag at subsonic speeds and can be a major portion of the drag at high supersonic and hypersonic speeds.

The amount of viscous resistance depends greatly on whether the flow is laminar or turbulent, that is, whether the paths of the fluid particles remain in parallel layers or move in a chaotic or fluctuating fashion from layer to layer. The Reynolds number and the shape of the pressure distribution determine whether the flow over the wing is laminar or turbulent or a mixture of both. For practical considerations, transition from laminar to turbulent flow on a straight wing can be assumed to occur at a Reynolds number of approximately one million, based on distance from the leading edge. This usually corresponds to a position close to the leading edge. Transition will occur at an even lower Reynolds number on a swept wing. Accordingly, the methods presented for the subsonic, transonic, and supersonic regimes are for a fully turbulent boundary layer. In the hypersonic regime, however, the boundary layer is more likely to be laminar, because of the low Reynolds numbers associated with flight in the upper flight corridor.

Pressure Drag

At subsonic speeds pressure drag is usually small compared to skin-friction drag. It is caused by the displacement thickness of the boundary layer, which prevents full pressure recovery at the trailing edge. At transonic and supersonic speeds, pressure drag is identified with wave drag and is quite significant.

A. SUBSONIC

Methods for predicting subsonic zero-lift drag for wings are necessarily empirical and are commonly based on streamwise airfoil thickness ratio. The most frequently used method appears in chapter VI of reference 1 and in such standard references as reference 2. The Datcom method is essentially that of reference 1, but it has been refined by applying a lifting-surface correlation factor from reference 3 which accounts for the increased Reynolds-number length due to spanwise flow.

The Datcom method, taken from reference 3, is applicable to the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal planforms)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee wings)

DATCOM METHOD

The subsonic wing zero-lift drag coefficient, based on the reference area S_{ref}, is given by

$$C_{D_0} = C_f \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] R_{L.S.} \frac{S_{wet}}{S_{ref}} \qquad 4.1.5.1\text{-a}$$

where

C_f is the turbulent flat-plate skin-friction coefficient from figure 4.1.5.1-26 as a function of Mach number and the Reynolds number based on the reference length ℓ. Figure 4.1.5.1-27 is used in conjunction with figure 4.1.5.1-26 to determine C_f. Figure 4.1.5.1-27 presents the admissible roughness ℓ/k as a function of the Reynolds number based on the reference length.

- ℓ is the reference length in inches—for a wing (or wing panel in the case of composite wings) the length of the mean aerodynamic chord $\bar{c}$.
- k is the surface-roughness height in inches; it depends upon surface finish. Representative values for this parameter can be obtained from table 4.1.5.1-A.

The ratio ℓ/k is computed and figure 4.1.5.1-27 is used to obtain the cutoff Reynolds number. If the cutoff Reynolds number is greater than the computed Reynolds number for the specific configuration, the value of C_f is obtained from figure 4.1.5.1-26 at the computed Reynolds number. If the cutoff Reynolds number is less than the computed Reynolds number, the value of C_f is obtained from figure 4.1.5.1-26 at the cutoff Reynolds number.

$\frac{t}{c}$ is the average streamwise thickness ratio of the wing (or wing panel in the case of composite wings).

L is the airfoil thickness location parameter. $L = 1.2$ for $(t/c)_{max}$ located at $x_t \geq 0.30c$. $L = 2.0$ for $(t/c)_{max}$ located at $x_t < 0.30c$ (x_t is the chordwise position of maximum thickness).

S_{wet} is the wetted area of the wing (or wing panel in the case of composite wings).

S_{ref} is the reference area.

$R_{L.S.}$ is the lifting-surface correction factor obtained from figure 4.1.5.1-28b as a function of the Mach number and the cosine of the sweep angle of the airfoil maximum thickness line of the wing (or wing panel in the case of composite wings). The solid curves of figure 4.1.5.1-28b were developed in reference 4 from wing-alone test data for conventional trapezoidal planforms (including delta wings) having round-nosed airfoil sections. The dashed curves of figure 4.1.5.1-28b are from reference 3 and are arbitrary in the sense that no experimental data are available to justify their use.

Figure 4.1.5.1-28b is used in the following manner:

$R_{L.S.}$	Conventional trapezoidal planforms (including delta wings)	Read value from solid curves.
	Non-straight-tapered wings	Read value from solid curves for outboard panels.
		Read value from dashed curves for inboard panels when $\cos\Lambda_{(t/c)_{max}} < 0.65$.

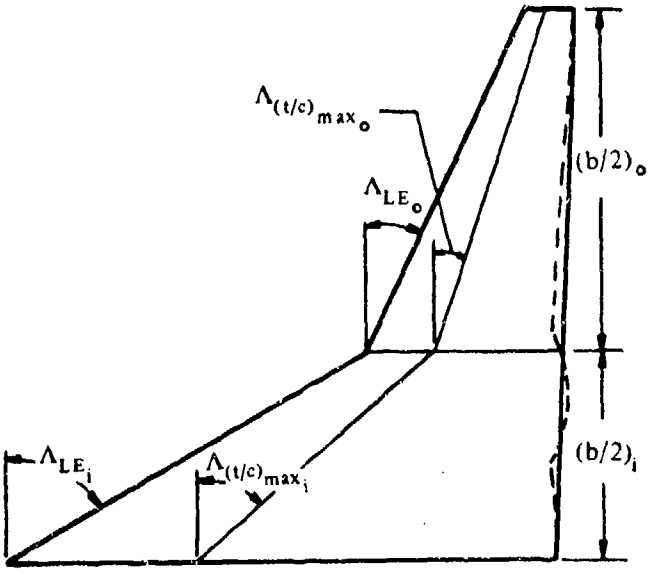
Non-straight-tapered-wing geometric parameters are presented in Section 2.2.2.

In treating non-straight-tapered planforms equation 4.1.5.1-a is applied to both the inboard and the outboard panels separately (based on a common reference area) and then summed. Curved planforms are approximated by combinations of trapezoidal panels, in which case two such panels are usually sufficient to give a satisfactory result.

For convenience, the bracketed term in equation 4.1.5.1-a is presented in figure 4.1.5.1-28a as a function of t/c and L. It should also be pointed out that the last term in equation 4.1.5.1-a represents the pressure drag of the wing.

Sample Problem

Given: The cranked wing of reference 23.



Inboard Panel:

NACA 63A004.5 airfoil (x_t @ 0.35c)

$(t/c)_i = 0.045$ $\quad \left(\frac{b}{2}\right)_i = 1.594$ ft

$\Lambda_{LE_i} = 60^o$ $\quad \Lambda_{(t/c)_{max_i}} = 48.4^o$

$\lambda_i = 0.339$ $\quad c_{r_i} = 4.175$ ft

$A_i = 1.14$ $\quad S_i = 8.91$ sq ft

$\left(S_{wet}\right)_i = 17.82$ sq ft

$\overline{c_i} = 3.02$ ft

Outboard Panel:

NACA 63A006 airfoil (x_t @ 0.35c) $\quad \left(\frac{b}{2}\right)_o = 2.606$ ft $\quad (t/c)_o = 0.06$

$\Lambda_{LE_o} = 25^o$ $\quad \Lambda_{(t/c)_{max_o}} = 18.1^o$ $\quad \lambda_o = 0.265$ $\quad c_{r_o} = 1.415$ ft

$A_o = 5.824$ $\quad S_o = 4.665$ sq ft $\quad \left(S_{wet}\right)_o = 9.33$ sq ft $\quad \overline{c}_o = 0.996$ ft

Additional Characteristics:

$M = 0.13$ $\quad R_\ell = 0.90 \times 10^6$ per ft $\quad$ Smooth surface (assume $k = 0$)

$S_{ref} = S_W = 13.575$ sq ft

Compute:

Inboard Panel

$R_\ell = (0.90 \times 10^6)(\bar{c}_i) = (0.90 \times 10^6)(3.02) = 2.718 \times 10^6$

$\frac{\ell}{k} = \infty$; read $\left(C_f\right)_i$ at calculated R_ℓ

$\left(C_f\right)_i = 0.00372$ (figure 4.1.5.1-26)

$\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_i = 1.053$ (figure 4.1.5.1-28a, for $L = 1.2$)

$\cos \Lambda_{(t/c)_{max_i}} = \cos 48.4^o = 0.6639$

$\left(R_{L.S.}\right)_i = 0.934$ (figure 4.1.5.1-28b)

$\frac{\left(S_{wet}\right)_i}{S_{ref}} = \frac{17.82}{13.575} = 1.313$

Outboard Panel:

$R_\ell = (0.90 \times 10^6)(\bar{c}_o) = (0.90 \times 10^6)(0.996) = 0.896 \times 10^6$

$\frac{\ell}{k} = \infty$; read $\left(C_f\right)_o$ at calculated R_ℓ

$\left(C_f\right)_o = 0.00451$ (figure 4.1.5.1-26)

$\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_o = 1.072$ (figure 4.1.5.1-28a, for $L = 1.2$)

$\cos \Lambda_{(t/c)_{max_o}} = \cos 18.1^o = 0.9505$

$\left(R_{L.S.}\right)_o = 1.067$ (figure 4.1.5.1-28b)

$\frac{\left(S_{wet}\right)_o}{S_{ref}} = \frac{9.33}{13.575} = 0.687$

Solution:

$$C_{D_0} = \left(C_{D_0}\right)_i + \left(C_{D_0}\right)_o$$

$$\left(C_{D_0}\right)_i = \left(C_f\right)_i \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_i \left(R_{L.S.}\right)_i \frac{\left(S_{wet}\right)_i}{S_{ref}} \quad \text{(equation 4.1.5.1-a)}$$

$$= (0.00372)(1.053)(0.934)(1.313) = 0.00480$$

$$\left(C_{D_0}\right)_o = \left(C_f\right)_o \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_o \left(R_{L.S.}\right)_o \frac{\left(S_{wet}\right)_o}{S_{ref}} \quad \text{(equation 4.1.5.1-a)}$$

$$= (0.00451)(1.072)(1.067)(0.687) = 0.00354$$

$$C_{D_0} = (0.00480) + (0.00354) = 0.00834$$

This compares with a test value of 0.0086 from reference 23.

B. TRANSONIC

The transonic range varies greatly with airfoil shape and thickness, but for the purposes of consistency with the bulk of the Datcom it can be considered to begin at approximately $M = 0.6$ and to end at $M = 1.2$. The drag rise which marks the actual beginning of the transonic range occurs when the local Mach number on some part of the wing exceeds 1.0 and shock waves form on the surface.

Because of the mixed flows, drag in the transonic range does not lend itself either to simple theoretical or to experimental analysis. As in the subsonic regime, the total zero-lift drag can be separated into two parts–skin friction drag due to viscous forces and "wave" or pressure drag due to the viscous dissipation associated with the formation of shock waves on the wing.

In the lower transonic range the shock waves are essentially normal to the surface and serve to decelerate local supersonic flow back to subsonic values. In the upper transonic region there are two shocks, a bow shock ahead of the airfoil and a trailing-edge shock located near the trailing edge. When the bow shock attaches itself to a sharp-nosed airfoil, the entire flow field over the surface becomes supersonic, thus ending the transonic region. For round-nosed airfoils the end of this range is less clearly defined, but it occurs when the bow wave stands very close to the nose and supersonic flow predominates.

Skin Friction

Although it might be reasoned that skin friction should be increased for subsonic compressible flow (lower transonic range) because of the relatively higher local velocities, experimental results show little increase in drag due to viscosity. This is probably due to the compensating effects of Reynolds number and Mach number as well as unpredictable changes in the transition point throughout the Mach number range. Therefore, for the purpose of the Datcom the skin-friction drag will be assumed to be constant and equal to the subsonic value at $M = 0.6$ throughout the transonic range.

Wave Drag

For a given airfoil, it is possible to estimate the critical Mach number and subsequent drag rise accurately. However, the variables involved in a wing design that affect the manner in which the shock waves develop

on the surface, and hence the drag-rise characteristics, are many. They include not only sweep, aspect ratio, taper ratio, and thickness ratio, but also the variations between root and tip in thickness, position of maximum thickness, incidence, and leading-edge geometry. Also, wings designed to fly transonically usually include some treatment, often made by contouring the fuselage, to minimize the "kink" effect at the root and tip. A wing can be designed to become critical from root to tip at the same time and have a flat drag curve with a delayed abrupt steep drag rise. Another wing can be designed which has an identical planform and the same average thickness ratio but has an entirely different shock development, producing a very gradual drag rise starting at a much lower Mach number.

For this reason, it is very difficult to correlate data in this region even on the basis of similarity parameters. The method presented here should be used only for first-order approximations on wings of relatively simple geometry. For cases where the design is aimed at optimizing transonic characteristics, detailed analysis of the isobar development on the wing must be made, in order to arrive at a reasonable drag estimate.

Since the transonic range begins when the first shocks form on the wing and ends when supersonic flow predominates, the amount of wave drag varies from zero at the lower speed to a peak value at the higher speeds within this range. From the standpoint of drag analysis, it is therefore convenient to relate this increase in drag to several parameters. These are discussed below.

The Mach Number for Drag Divergence

The free-stream Mach number at which sonic velocity is first attained on some portion of the wing is called the "theoretical critical Mach number." However, since experimental evidence indicates that there are no abrupt changes in force characteristics until the critical Mach number is exceeded by a substantial amount, it is usual to define the Mach number at which the drag starts to increase rapidly as the drag-divergence Mach number. It is further arbitrarily defined in the literature as the Mach number at which the numerical value of the slope of the curve of C_D vs M is 0.10.

$$M_D = M \left(\frac{\partial C_D}{\partial M} \right)_{C_L = \text{const}} = 0.10 \qquad \text{4.1.5.1-b}$$

The Maximum Wave-Drag Increment and the Mach Number at Which It Occurs

For two-dimensional airfoils, the peak wave drag occurs near M = 1.0. Linear theory predicts a pressure coefficient inversely proportional to $(1 - M^2)$ in high subsonic flow and $(M^2 - 1)$ in supersonic flow; thus indicating a maximum value near 1.0. In practice, however, the magnitude of this peak and the Mach number at which it occurs vary greatly with airfoil thickness, section shape, aspect ratio, and sweep; consequently, no reliable method has been devised to predict these values accurately.

The most useful tools available for correlating data in estimating wave drag in the transonic range are the von Kármán similarity laws (reference 5). These laws state that for two-dimensional flow, the flow pattern over two airfoils must be the same if the value of $(t/c)^{1/3} \mid 1 - M^2 \mid$ has the same value for each airfoil. Hence, if drag is known for one wing section as a function of Mach number, the corresponding quantity for similar sections can be computed by the simple relation $C_D \propto (t/c)^{5/3}$. Extensions of these laws have been made by Busemann and Spreiter to include three-dimensional effects (references 6 and 7).

The Datcom method is applicable only to conventional, trapezoidal planforms.

DATCOM METHOD

The zero-lift drag coefficient of conventional, trapezoidal planforms over the transonic speed regime is approximated by the following steps:

Step 1. Determine the skin-friction drag coefficient at M = 0.60 by

$$C_{D_f} = C_f \left[1 + L\left(\frac{t}{c}\right)\right] \frac{S_{wet}}{S_{ref}} \qquad 4.1.5.1\text{-c}$$

where C_{D_f} is the skin-friction drag coefficient based on the reference area, and the remaining parameters are defined in the Datcom method of paragraph A. This value, calculated at M = 0.6, is assumed to be constant throughout the transonic region.

Step 2. Determine the wave-drag coefficient C_{D_w} at transonic Mach numbers for an unswept wing and construct the curve of C_{D_w} vs Mach number for the appropriate thickness and aspect ratio from figure 4.1.5.1-29. Values of $(t/c)^{1/3}$ and $(t/c)^{5/3}$ are given below to facilitate calculation:

t/c	$(t/c)^{1/3}$	$(t/c)^{5/3}$
0.12	0.493	0.0293
0.11	0.479	0.0254
0.10	0.464	0.0217
0.09	0.448	0.0181
0.08	0.431	0.0148
0.07	0.412	0.0118
0.06	0.392	0.0092
0.05	0.368	0.0068
0.04	0.342	0.00468
0.03	0.311	0.00292
0.02	0.271	0.00147

Step 3. From the curve of C_{D_w} vs M, read $C_{D_{w_{peak}}\Lambda_{c/4}=0}$, $M_{C_{D_{w_{peak}}}\Lambda_{c/4}=0}$, and $M_{D\Lambda_{c/4}=0}$. The Mach number for drag divergence $M_{D\Lambda_{c/4}=0}$ is obtained by a graphical interpretation of equation 4.1.5.1-b; i.e., $M_{D\Lambda_{c/4}=0}$ is read at the point of tangency to the C_{D_w} vs M curve of a line whose slope is $\partial C_D / \partial M = 0.10$.

Step 4. For a wing having sweep, convert values from the straight-wing curve as follows:

$$M_{D\Lambda_{c/4}=n} = \frac{M_{D\Lambda_{c/4}=0}}{(\cos n)^{1/2}} \qquad 4.1.5.1\text{-d}$$

$$C_{D_{w_{peak}}\Lambda_{c/4}=n} = C_{D_{w_{peak}}\Lambda_{c/4}=0} (\cos n)^{2.5} \qquad 4.1.5.1\text{-e}$$

$$M_{C_{D_{w_{peak}}} \Lambda_{c/4} = n} = \frac{M_{C_{D_{w_{peak}}} \Lambda_{c/4} = 0}}{(\cos n)^{1/2}} \qquad 4.1.5.1\text{-f}$$

Step 5. Construct the curve of C_{D_w} vs M for the swept wing by using the values determined in step 4 and the straight-wing curve of C_{D_w} vs M to aid in fairing.

Step 6. The zero-lift drag coefficient is obtained by adding the constant value of skin-friction drag coefficient determined in step 1 to the wave-drag over the transonic speed range determined in step 2 for unswept wings or in step 5 for swept wings.

$$C_{D_0} = C_{D_f} + C_{D_w} \qquad 4.1.5.1\text{-g}$$

Sample Problem

Given: The zero-taper-ratio wing of reference 24.

$A = 4.0$ $\quad \lambda = 0$ $\quad \Lambda_{c/4} = 14.5^o$ $\quad S_{wet} = 1.390$ sq ft

NACA 63A006 airfoil (x_t @ 0.35c)

Additional characteristics:

$R_{\ell_{M=0.6}} = 1.4 \times 10^6$ (based on $\bar{c}$) $\quad S_{ref} = S_W = 0.695$ sq ft

Smooth surface (assume k = 0)

Compute:

Determine the skin-friction drag coefficient.

$\frac{\ell}{k} = \infty$; read C_f at given R_ℓ at M = 0.6.

$C_f = 0.0042$ (figure 4.1.5.1-26)

$$C_{D_f} = C_f \left[1 + L\left(\frac{t}{c}\right)\right] \frac{S_{wet}}{S_{ref}} \qquad \text{(equation 4.1.5.1-c)}$$

$$= 0.0042\,[1 + (1.2)(0.06)]\,\frac{1.390}{0.695}$$

$= 0.0090$ (based on S_W)

Determine and construct the variation of C_{D_w} with Mach number for an unswept wing.

$$A\left(\frac{t}{c}\right)^{1/3} = (4.0)\,(0.392) = 1.568$$

① M	② $\frac{\sqrt{\lvert M^2-1\rvert}}{(t/c)^{1/3}}$	③ $\frac{C_{D_w}}{(t/c)^{5/3}}$ fig. 4.1.5.1-29	④ C_{D_w} ③ (0.0092)

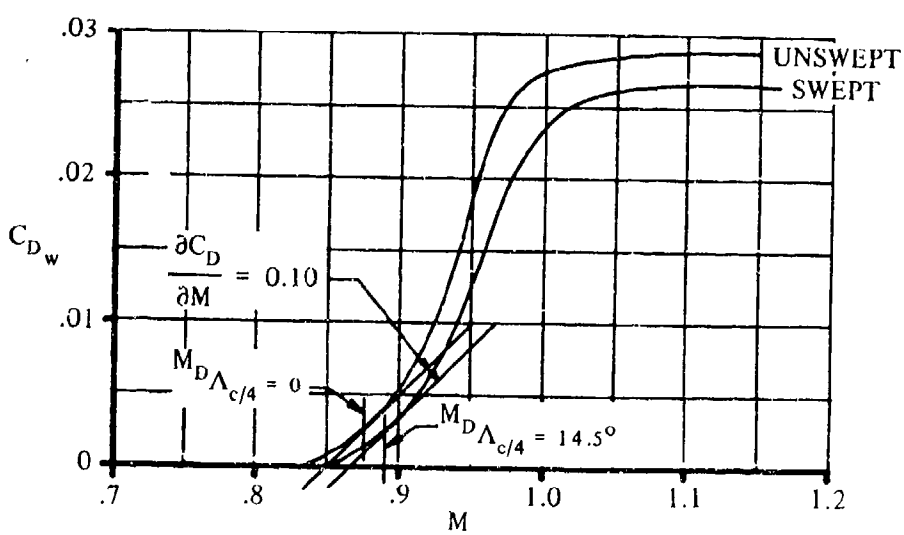
1.15	1.45	3.13	0.0288

Plot C_{D_w} vs M for the unswept wing (sketch (a)).



SKETCH (a)

Read the following values from the curve of C_{D_w} vs M for the unswept wing.

$$M_{D_{\Lambda_{c/4}=0}} = 0.875$$

$$C_{D_{w_{peak}\Lambda_{c/4}=0}} = 0.029$$

$$M_{C_{D_{w_{peak}\Lambda_{c/4}=0}}} = 1.10$$

Apply sweep corrections

$$M_{D_{\Lambda_{c/4}=14.5^\circ}} = \frac{M_{D_{\Lambda_{c/4}=0}}}{(\cos 14.5^\circ)^{1/2}} = \frac{0.875}{(0.9681)^{1/2}} = 0.889 \quad \text{(equation 4.1.5.1-d)}$$

$$C_{D_{w_{peak}\Lambda_{c/4}=14.5^\circ}} = C_{D_{w_{peak}\Lambda_{c/4}=0}} (\cos 14.5^\circ)^{2.5} \quad \text{(equation 4.1.5.1-e)}$$

$$= (0.029)\,(0.9681)^{2.5}$$

$$= 0.0267$$

$$M_{C_{D_{w_{peak}\Lambda_{c/4}=14.5^\circ}}} = \frac{M_{C_{D_{w_{peak}\Lambda_{c/4}=0}}}}{(\cos 14.5^\circ)^{1/2}} \quad \text{(equation 4.1.5.1-f)}$$

$$= \frac{1.10}{(0.9681)^{1/2}}$$

$$= 1.12$$

Construct the curve of C_{D_w} vs M for the swept wing using the straight-wing curve to aid in fairing.

Solution:

$$C_{D_0} = C_{D_f} + C_{D_w} \quad \text{(equation 4.1.5.1-g)}$$

① M	② C_{D_f}	③ C_{D_w} sketch (a)	④ C_{D_0} ② + ③

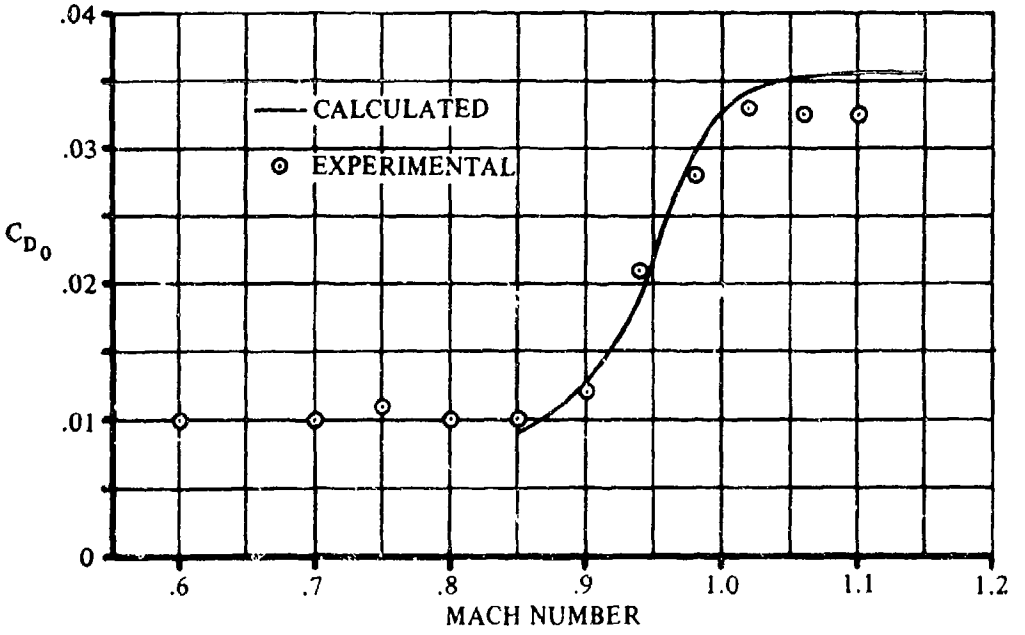
The calculated results are compared with test values from reference 24 in sketch (b).



SKETCH (b)

C. SUPERSONIC

Skin Friction

At supersonic speeds it can be shown theoretically that an increase in Mach number results in a decrease in the skin-friction coefficient at constant Reynolds number. This variation, when zero heat transfer is assumed, is due primarily to the variations in temperature and density. In actual cases, where the airplane is transmitting heat to the boundary layer, or where the aircraft is cooled to a point where heat from the boundary layer is transmitted to the skin, the reduction in skin-friction coefficient becomes a function of the heat-transfer condition. The full reduction in skin friction at supersonic Mach numbers is justified only when stabilized conditions and zero heat transfer are attained. Therefore, to obtain accurate supersonic skin-friction coefficients, it is necessary to know the heat-transfer conditions on various portions of a flight vehicle throughout its mission. Since this information can be obtained only by detailed analysis, some assumptions regarding the skin friction are usually made. For flights of long duration, equilibrium (zero heat transfer) is generally assumed. For transient flight, the skin-friction coefficient will vary between the incompressible value and that for zero heat transfer. Another important consideration for estimating the skin-friction drag at supersonic speeds is the Reynolds-number variation throughout the flight regime. The design chart used in the Datcom method presents the turbulent skin-friction coefficient on an insulated flat plate as a function of Mach number and Reynolds number.

Wave Drag

Numerous theories are available for calculating the wave drag of wing planforms at supersonic speeds. No attempt is made to discuss all of these theories and their limitations; however, table 4.1.5.1-B presents a summary of various planforms for which solutions exist. In general, the well-known linear supersonic theory has proved useful in indicating the trends of wing wave drag for the majority of conventional, tapered, trapezoidal planforms with subsonic leading edges (see reference 8).

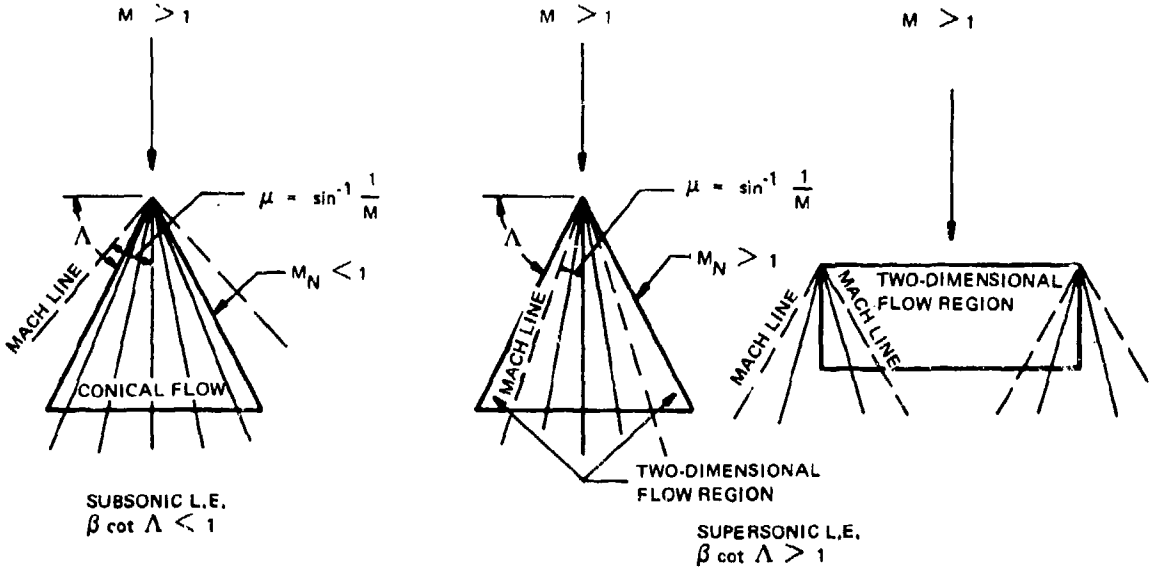
In discussing the flow regions over a wing, the following general classifications are convenient (see sketch (c)).

Subsonic Wing Leading Edge—If the leading edge of the wing is swept behind the Mach cone, the velocity component normal to the leading edge is subsonic and hence the leading edge is said to be subsonic.

Supersonic Wing Leading Edge--If the leading edge is forward of the Mach cone, the normal velocity component is supersonic and the wing is said to have a supersonic leading edge.

Similar terminology can be applied to the wing trailing edges. For either subsonic or supersonic leading edges the region inside the Mach cone is called the "conical flow" region. In this region the velocity components are constant along rays emanating from the apex and the flow is not influenced by the presence of the tip or trailing edge.

When the leading edge is supersonic, the region outside the Mach cone is called the "two-dimensional flow" region and the velocity distribution in this region is identical to that of an infinite wing having the same leading-edge sweep.



SKETCH (c)

It should be pointed out that due to the approximations of linear theory, kinks occur in the drag curves when lines across which the flow is turned become sonic, namely, leading and trailing edges and ridge lines of polygonal sections. These kinks do not occur in practice, since they correspond to flow conditions for which linear theory is no longer valid.

The Datcom method for estimating supersonic wave drag is taken from reference 3 and is based on the results that have been obtained from linear supersonic theory for the two-dimensional case.

The Datcom method is applicable to the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal planforms)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

DATCOM METHOD

The wing zero-lift drag coefficient at supersonic speeds, based on the reference area S_{ref}, is given by

$$C_{D_0} = C_{D_f} + C_{D_w} \qquad 4.1.5.1\text{-h}$$

where C_{D_f} and C_{D_w} are the supersonic skin-friction drag coefficient and the supersonic wave-drag coefficient, respectively, both based on a common reference area, and determined in the following manner:

Skin-Friction Drag Coefficient

The supersonic skin-friction drag coefficient is given by

$$C_{D_f} = C_f \frac{S_{wet}}{S_{ref}} \qquad 4.1.5.1\text{-i}$$

for a conventional, trapezoidal planform, and

$$C_{D_f} = \left(C_f\right)_i \frac{\left(S_{wet}\right)_i}{S_{ref}} + \left(C_f\right)_o \frac{\left(S_{wet}\right)_o}{S_{ref}} \qquad 4.1.5.1\text{-j}$$

for a non-straight-tapered planform.

where

C_f is the turbulent flat-plate skin-friction coefficient from figure 4.1.5.1-26 as a function of Mach number and the Reynolds number based on the reference length ℓ. The reference length ℓ is the mean aerodynamic chord of the wing (or wing panel in the case of composite wings). Figure 4.1.5.1-27 is used in conjunction with figure 4.1.5.1-26 to determine C_f. The procedure for determining C_f is fully explained in the Datcom method of paragraph A.

$\frac{S_{wet}}{S_{ref}}$ is the ratio of the wetted area of the wing (or wing panel in the case of composite wings) to the reference area.

The subscripts i and o refer to the inboard and outboard panels, respectively, of composite planforms.

Curved planforms are approximated by combinations of trapezoidal panels, in which case two such panels are usually sufficient to give a satisfactory result.

Non-straight-tapered wing geometric parameters are presented in Section 2.2.2.

Wave-Drag Coefficient

The form of the equation for the supersonic wave-drag coefficient is in accordance with the results that have been obtained from linear supersonic theory for the two-dimensional case. The effects of changes in wing planform and variable thickness ratio are accounted for by defining an effective thickness ratio and computing the wave-drag coefficient on a basic planform shape. A distinction is made between wings with sharp-nosed airfoil sections and wings with round-nosed airfoil sections.

Wings With Sharp-Nosed Airfoil Sections

For wings with sharp-nosed airfoil sections

$$C_{D_w} = \frac{K}{\beta}\left(\frac{t}{c}\right)^2_{eff} \frac{S_{bw}}{S_{ref}} \qquad 4.1.5.1\text{-k}$$

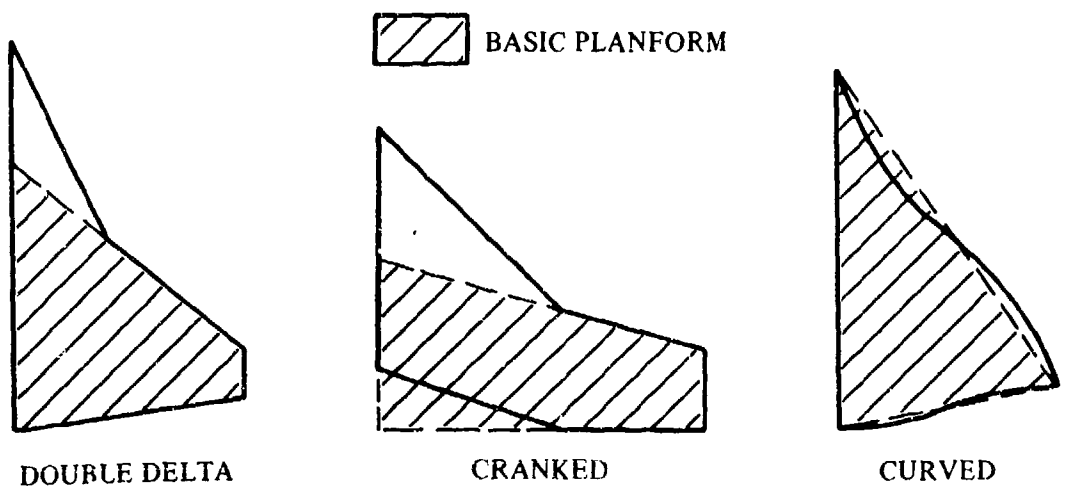
when the leading edge of the basic wing is supersonic $\left(\beta \cot \Lambda_{LE_{bw}} \geq 1\right)$, and

$$C_{D_w} = K \cot \Lambda_{LE_{bw}} \left(\frac{t}{c}\right)^2_{eff} \frac{S_{bw}}{S_{ref}} \qquad 4.1.5.1\text{-}\ell$$

when the leading edge of the basic wing is subsonic $\left(\beta \cot \Lambda_{LE_{bw}} < 1\right)$.

The subscript bw refers to the basic wing (straight leading and trailing edges), and

S_{bw} is the area of the basic wing – for conventional, trapezoidal planforms, the total wing area. The selection of the basic planform for non-straight-tapered wings is arbitrary, but should deviate as little as possible from the actual wing. Typical non-straight-tapered wings and the basic planforms used in wave-drag estimations are illustrated in sketch (d).



DEFINITION OF BASIC PLANFORMS OF NON-STRAIGHT-TAPERED WINGS FOR SUPERSONIC WAVE-DRAG ESTIMATION

SKETCH (d)

$\left(\frac{t}{c}\right)_{eff}$ is the effective thickness ratio (for a conventional, trapezoidal planform, use the average thickness ratio $(t/c)_{av}$). For a nonstraight-tapered planform the effective thickness ratio is defined in terms of the basic planform and is given by

$$\left(\frac{t}{c}\right)_{eff} = \left[\frac{\int_0^{b/2} \left(\frac{t}{c}\right)^2 c_{bw}\, dy}{\int_0^{b/2} c_{bw}\, dy}\right]^{1/2} \qquad 4.1.5.1\text{-}m$$

where c_{bw} is the chord of the basic wing. Note that in the numerator, the chord of the actual wing and the chord of the basic wing both appear. The denominator is one-half the planform area of the basic wing, so that

$$\left(\frac{t}{c}\right)_{eff} = \frac{\left[\int_0^{b/2} \left(\frac{t}{c}\right)^2 c_{bw}\, dy\right]^{1/2}}{\left(\frac{S_{bw}}{2}\right)^{1/2}} \qquad 4.1.5.1\text{-}m'$$

Numerical integration of the integrand in the numerator is illustrated in the sample problem.

$\Lambda_{LE_{bw}}$ is the leading-edge sweep of the basic wing.

K is a constant factor for a given sharp-nosed airfoil section. For basic wings with variable thickness ratios the K factor is based on the airfoil section at the average chord. K factors for sharp-nosed airfoils are presented in the following table:

SHARP-NOSED AIRFOILS

Basic Wing Airfoil Section	K	Se ı
Biconvex	$\frac{16}{3}$	Double Wedge	$\frac{c/x_t}{1 - x_t/c}$	Hexagonal	$\frac{c\,(c - x_2)}{x_1\, x_3}$	
Wings With Round-Nosed Airfoil Sections

Wings with round-nosed airfoil sections exhibit a detached bow wave and a stagnation point, and the pressure-drag coefficient increases as a function of Mach number in a manner similar to the stagnation pressure. Consequently, a constant value of K cannot be used for basic wings with round-nosed airfoils.

The wave-drag coefficient of wings with round-nosed airfoil sections is approximated by adding the pressure drag of a blunt leading edge to the wave drag of the basic wing with an assumed sharp leading edge. By assuming a biconvex shape aft of the leading edge, the wave drag of a round-nosed leading-edge wing is given by

$$C_{D_w} = C_{D_{LE}} + \frac{16}{3\beta}\left(\frac{t}{c}\right)^2_{eff} \frac{S_{bw}}{S_{ref}} \qquad 4.1.5.1\text{-n}$$

when the leading edge of the basic wing is supersonic $\left(\beta \cot \Lambda_{LE_{bw}} \geq 1\right)$, and

$$C_{D_w} = C_{D_{LE}} + \frac{16}{3} \cot \Lambda_{LE_{bw}} \left(\frac{t}{c}\right)^2_{eff} \frac{S_{bw}}{S_{ref}} \qquad 4.1.5.1\text{-o}$$

when the leading edge of the basic wing is subsonic $\left(\beta \cot \Lambda_{LE_{bw}} < 1\right)$.

The second terms on the right-hand side of equations 4.1.5.1-n and 4.1.5.1-o are the wave-drag coefficients of the basic wing with sharp-nosed, biconvex airfoils at the appropriate leading-edge condition, and

$C_{D_{LE}}$ is the pressure-drag coefficient on a swept, cylindrical leading edge obtained as a function of the Mach number and the leading-edge sweep of the basic wing from figure 4.1.5.1-30a or figure 4.1.5.1-30b. The term $\left(2r_{LE_{bw}} \; b_{bw}/\cos \Lambda_{LE_{bw}}\right)$ is the frontal area of the leading edge. For basic wings with variable thickness ratios the leading-edge radius $r_{LE_{bw}}$ is the radius of the section at the average chord.

The correlation of cylindrical leading-edge pressure-drag coefficients is derived in reference 19 and has been substantiated over the Mach number range from 0.5 to 8.0 and for sweep angles from 0 to 75^{o}.

Sample Problem

Given: The double-delta wing designated 6-67-67, of reference 25.

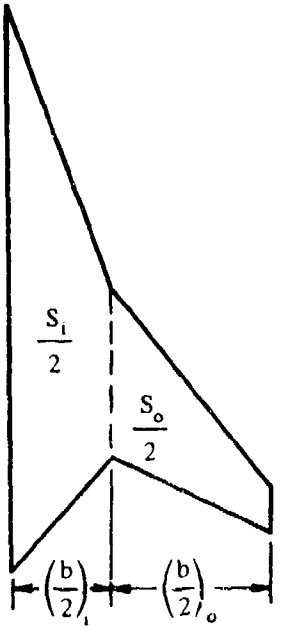
Actual Wing Characteristics:

$A = 2.42$ $\quad \lambda = 0.086$ $\quad \Lambda_{LE_i} = 70.67^{o}$ $\quad \Lambda_{LE_o} = 51.63^{o}$

$\Lambda_{TE_i} = -47.38^{o}$ $\quad \Lambda_{TE_o} = 26.62^{o}$ $\quad \frac{b}{2} = 12.0$ in. $\quad \eta_B = 0.40$

$S_W = S_{ref} = 238$ sq in. $\quad \frac{t}{c}$ varies, (see sketch (e))

Inboard- and Outboard-Panel Characteristics (skin-friction drag calculations):



Inboard panel:

$c_{r_i} = 26.58$ in. $\quad \lambda_i = 0.293$ $\quad \overline{c_i} = 18.9$ in.

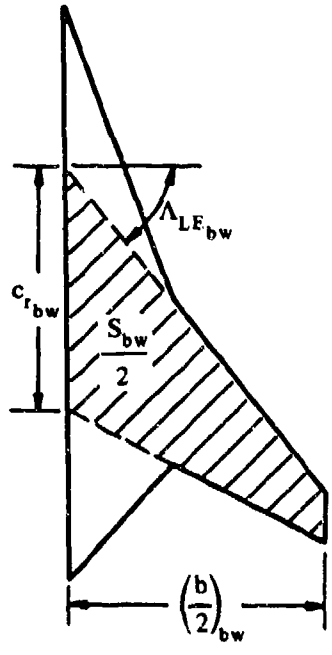
$S_i = 165$ sq in. $\quad \left(S_{wet}\right)_i = 330$ sq in.

Outboard panel:

$c_{r_o} = 7.77$ in. $\quad \lambda_o = 0.2995$ $\quad \overline{c_o} = 5.54$ in.

$S_o = 73$ sq in. $\quad \left(S_{wet}\right)_o = 146$ sq in.

Basic Wing Characteristics (wave-drag calculations):



$c_{r_{bw}}$ = 11.43 in. $\quad \lambda_{bw}$ = 0.20

$\Lambda_{LE_{bw}}$ = 51.63° $\quad \Lambda_{TE_{bw}}$ = 26.62°

$\left(\frac{b}{2}\right)_{bw}$ = 12.0 in. $\quad S_{bw}$ = 146.6 sq in.

Airfoil Characteristics:

Hexagonal, sharp leading edge

$\frac{x_1}{c} = \frac{x_2}{c} = \frac{x_3}{c} = \frac{1}{3}$ $\quad (t/c)_{bw}$ = 0.06 (constant)

Additional Characteristics:

M = 2.01; β = 1.744 $\quad$ Smooth surface (assume k = 0)

R_ℓ = 3.35 x 10^6 per ft

Compute:

Skin-friction drag coefficient

Inboard panel

$$R_\ell = (3.35 \times 10^6)(\bar{c}_i) = (3.35 \times 10^6)\left(\frac{18.9}{12}\right) = 5.28 \times 10^6$$

$\frac{\ell}{k} = \infty$; read $\left(C_f\right)_i$ at calculated R_ℓ

$\left(C_f\right)_i$ = 0.00255 (figure 4.1.5.1-26)

Outboard panel

$$R_\ell = (3.35 \times 10^6)(\bar{c}_o) = (3.35 \times 10^6)\left(\frac{5.54}{12}\right) = 1.55 \times 10^6$$

$\frac{\ell}{k} = \infty$; read $\left(C_f\right)_o$ at calculated R_ℓ

$\left(C_f\right)_o$ = 0.00318 (figure 4.1.5.1-26)

$$C_{D_f} = \left(C_f\right)_i \frac{\left(S_{wet}\right)_i}{S_{ref}} + \left(C_f\right)_o \frac{\left(S_{wet}\right)_o}{S_{ref}} \quad \text{(equation 4.1.5.1-j)}$$

$$= (0.00255)\left(\frac{330}{238}\right) + (0.00318)\left(\frac{146}{238}\right)$$

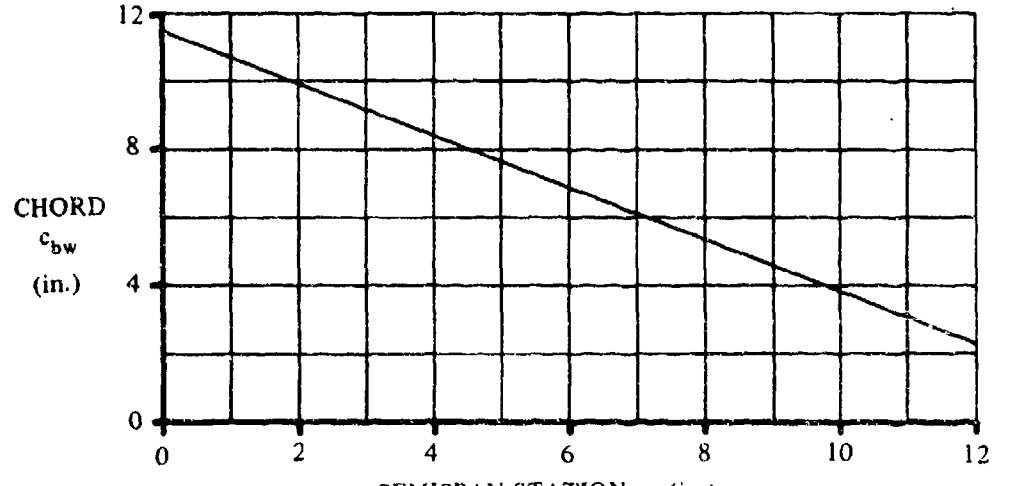
$$= 0.00548 \text{ (based on } S_{ref})$$

Wave-drag coefficient

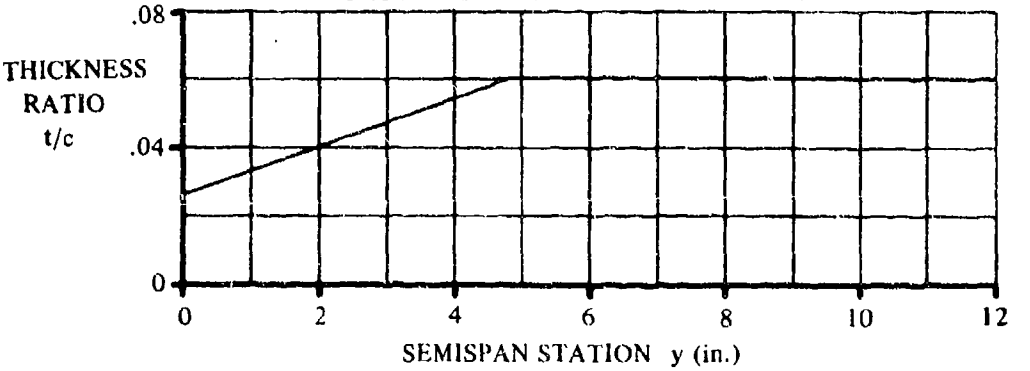
$$K = \frac{c\,(c - x_2)}{x_1\, x_3} = \frac{1\left(1 - \frac{1}{3}\right)}{\left(\frac{1}{3}\right)^2} = 6.0$$

Determine $(t/c)_{eff}$

The thickness distribution of the actual wing and the chord distribution of the basic wing are shown in sketch (e).



CHORD DISTRIBUTION (BASIC WING)



THICKNESS DISTRIBUTION (ACTUAL PLANFORM)

SKETCH (e)

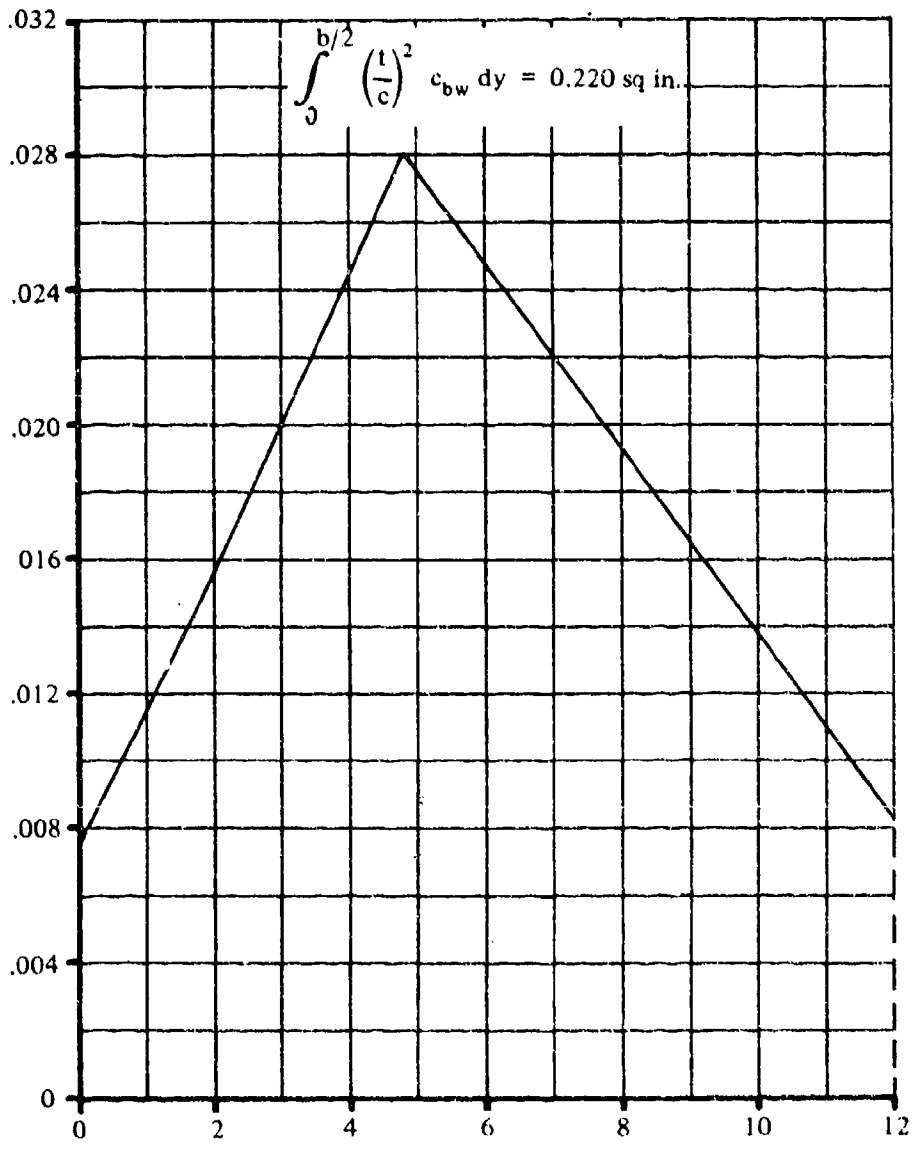
Sketch (f) shows $\left[(t/c)^2\, c_{bw}\right]$ versus spanwise position.

Graphical integration of this curve gives $\int_0^{b/2} \left(\frac{t}{c}\right)^2 c_{bw}\, dy = 0.220$ sq in.

$$\left(\frac{t}{c}\right)^2_{eff} = \frac{\int_0^{b/2} \left(\frac{t}{c}\right)^2 c_{bw}\, dy}{\frac{1}{2} S_{bw}} \qquad \text{(equation 4.1.5.1-m')}$$

$$= \frac{0.220}{\frac{1}{2}(146.6)} = 0.0030$$

$$\left(\frac{t}{c}\right)_{eff} = 0.0548$$



SKETCH (f)

$$\beta \cot \Lambda_{LE_{bw}} = (1.744)(\cot 51.63^{\circ}) = 1.381 \text{ (supersonic leading edge)}$$

$$C_{D_w} = \frac{K}{\beta}\left(\frac{t}{c}\right)^2_{eff}\frac{S_{bw}}{S_{ref}} \quad \text{(equation 4.1.5.1-k)}$$

$$= \left(\frac{6.0}{1.744}\right)(0.0548)^2\left(\frac{146.6}{238}\right)$$

$$= 0.00636 \quad \text{(based on } S_{ref})$$

Solution:

$$C_{D_0} = C_{D_f} + C_{D_w} \quad \text{(equation 4.1.5.1-h)}$$

$$= (0.00548) + (0.00636)$$

$$= 0.01184 \quad \text{(based on } S_{ref})$$

D. HYPERSONIC

The characteristics of hypersonic flow differ from those of supersonic flow in that

1. The shock waves in hypersonic flow lie close to the body causing a strong boundary-layer--shock-wave interaction which exerts an important influence on the flow field. The boundary layer in hypersonic flow may be 10 to 100 times thicker than at low speeds; consequently, a change in the effective body shape results,which in turn brings about a change in the shape of the nose shock wave.

2. High-temperature gas effects become evident at hypersonic speeds.

3. The flow becomes essentially nonlinear in nature.

4. Hypersonic similarity exists. It has been shown that at hypersonic Mach numbers the potential flow of similar airfoils is dynamically similar if the product $\beta(t/c)$ is a constant.

An approximate criterion for defining hypersonic flow is

$$\beta\frac{t}{c} \geq 0.5$$

Since, in hypersonic flow, β is very close to M, the relationship $M(t/c) = K_t$ is used as the hypersonic similarity parameter.

Because of the nonlinearity of hypersonic flow, approximate methods of estimating force characteristics are very desirable. Among the methods used, Newtonian and modified Newtonian theory have proved quite useful. Newtonian theory (reference 20) is based on the assumption that the shock coincides with the wing surfaces and that no friction exists between the wing and the shock layer. The fluid particles ahead of the wing are not disturbed until they encounter the wing surface, at which point the relative momentum normal to the surface is lost and the tangential flow has no further change in velocity. In this case, the air may be visualized as composed of discrete particles, which, after impact, travel parallel to the surface. When the particles reach the free-stream direction, they leave the surface, giving essentially zero pressure on the leeward side.

DATCOM METHOD

The drag at zero-lift is approximated by the drag of the forward-facing surface. Typical values of $C_{D_0}/2\tau^2$ for a wedge, as predicted by Newtonian theory, are presented in the following table from reference 20. (τ is one-half the thickness ratio of the forward-facing surface). It is to be noted that the drag can be reduced as much as one-half by optimization of the shape behind the initial wedge angle.

TYPICAL VALUES OF C_{D_0} FOR A WEDGE

Two-Dimensional
(Reference 20)

Shape	$\frac{1}{2\tau^2} C_{D_0}$	$\frac{C_{D_0}}{(C_{D_0})_{abs.\ opt.}}$
Wedge	1.000	2.000
0.864 Power	0.918	1.836
Proper Optimum	0.770	1.540
Absolute Optimum	0.500	1.000

Note that C_{D_0} is based on frontal area.

Detailed discussions of optimization methods are given in reference 20.

E. RAREFIED GAS

In the previous speed regimes it is assumed that the air behaves as a continuum. At very high altitudes, however, where very low densities are encountered, the actual molecular structure of the air becomes extremely important. Figure 4.1.5.1-32 presents a qualitative division of the various regimes of gas dynamics. It is to be noted that the region of rarefied gases is further divided into regions of varying amounts of rarefaction; i.e., "slip flow" or slightly rarefied, "transition" or moderately rarefied, and "free-molecule flow" or highly rarefied.

Slip Flow

The slip-flow region is of most interest to the aircraft and missile designer. In this region continuum theory becomes questionable, and satisfactory analytical results are uncommon, since the effects of slip flow are usually masked by large compressibility and viscous effects. Figure 4.1.5.1-33 (reference 21) presents test data points for skin friction in slip flow compared with incompressible theory for continuum flow (reference 22). It should be noted that in the subsonic case the test data are generally lower than the theoretical, while at supersonic speeds they are generally higher. This tends to confirm the theory that skin friction in the slip-flow regime is affected by two interrelated phenomena, the interaction of the thick boundary layer with the inviscid flow and the slip at the surface. The former is more important at the higher densities, gradually giving way to the latter for densities extending into the transition regime.

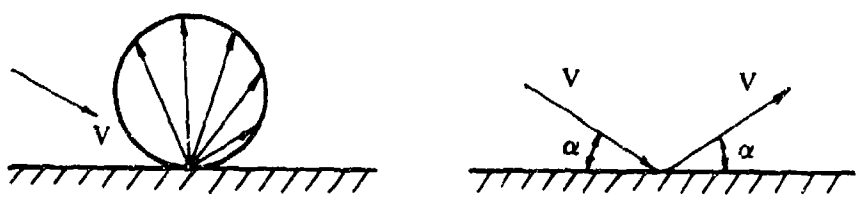
Transition Flow

Present knowledge about the transition regime is extremely limited and will not be covered here.

Free-Molecule Flow

In the free-molecule flow regime, the mean free path of the molecule is large compared to the characteristic dimension of an aerodynamic body in the flow, and the individual gas molecules striking the body do not interact with the surrounding molecules. For this reason the incident flow is assumed to be undisturbed by the presence of the body and no shock waves are expected to form. The boundary layer is very diffuse and has no effect on the flow incident on the body.

The problems associated with free-molecule flow are of particular interest to the satellite designer. In contrast to the other two regimes of rarefied-gas flow, the free-molecule regime can be treated analytically with less difficulty. The drag values of a flat plate with $\alpha = 0$ for diffuse and specular reflection are shown in figures 4.1.5.1-34a and 4.1.5.1-34b, respectively. Diffuse reflection is one in which the velocity of the reflected particles have a Maxwellian velocity distribution (see sketch (g)). Specular reflection is one in which the normal momentum is reversed at the surface and the tangential momemtum remains constant.



DIFFUSE REFLECTION SPECULAR REFLECTION

4.1.5.2 WING DRAG AT ANGLE OF ATTACK

The drag of a wing at angle of attack can be expressed in the form

$$C_D = C_{D_0} + C_{D_L}$$

where C_{D_0} is the zero-lift drag and the term C_{D_L} represents the drag due to lift. The zero-lift drag of a wing may be obtained by using the methods of Section 4.1.5.1. Methods are presented in this section for estimating the drag-due-to-lift term.

The drag due to lift of a wing increases approximately as the square of the lift coefficient or angle of attack and may be expressed in the form

$$C_{D_L} = \frac{K C_L^2}{\pi A} \qquad 4.1.5.2\text{-a}$$

where K is the drag-due-to-lift factor.

Equation 4.1.5.2-a can further be written as the sum of two terms, the well-known induced drag (or trailing-vortex drag) C_{D_i} and the viscous drag due to lift C_{D_v}, so that

$$C_{D_L} = C_{D_i} + C_{D_v} \qquad 4.1.5.2\text{-b}$$

These drag terms are discussed below.

Induced Drag

The induced drag depends on the wing spanwise loading distribution, since it results from the lift produced by the wing trailing-vortex system. The trailing-vortex system rotates the total wing-force vector rearward, giving the induced-drag component, which increases approximately as the square of the lift coefficient or angle of attack. Induced drag may be expressed as

$$C_{D_i} = \frac{C_L^2}{\pi A e^*} \qquad 4.1.5.2\text{-c}$$

where e^* is the induced span-efficiency factor (or wing span-efficiency factor with $C_{D_v} = 0$).

The theoretical minimum induced drag attainable is obtained from a wing with elliptic span loading, in which case an induced span-efficiency factor of 1.0 represents the theoretically ideal wing.

Viscous Drag Due to Lift

The viscous drag due to lift results from the change in boundary-layer development with lift over the wing. The upper-surface boundary layer increases in thickness as the angle of attack increases, which results in an increase in wing profile drag (skin-friction + pressure drag).

With the induced drag expressed by equation 4.1.5.2-c, the total drag due to lift is given by

$$C_{D_L} = \frac{C_L^2}{\pi A e^*} + C_{D_v} \qquad 4.1.5.2\text{-d}$$

Since the viscous drag due to lift also varies directly with C_L^2, the total drag due to lift is often expressed as

$$C_{D_L} = \frac{C_L^2}{\pi A e} \qquad 4.1.5.2\text{-e}$$

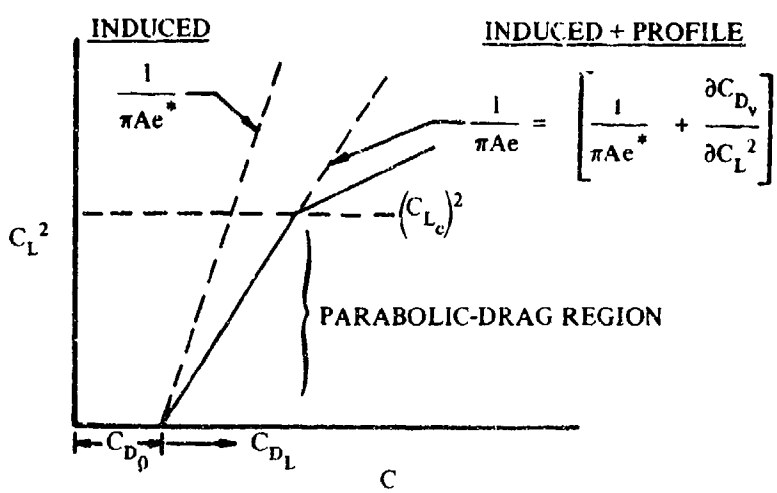
which is of the form of equation 4.1.5.2-a with the drag-due-to-lift factor K expressed as 1/e, where e is the span-efficiency factor, including the effect of viscosity. Therefore, the span-efficiency factor may be expressed in the familiar form

$$e = \frac{1}{\pi A \dfrac{\partial C_{D_L}}{\partial C_L^2}} \qquad 4.1.5.2\text{-f}$$

or, in the more basic form

$$e = \frac{1}{\pi A\left[\dfrac{1}{\pi A e^*} + \dfrac{\partial C_{D_v}}{\partial C_L^2}\right]} \qquad 4.1.5.2\text{-g}$$

The drag-due-to-lift factor is constant over a lift-coefficient range from zero to a certain value of C_L termed the "critical" lift coefficient C_{L_c}. Over this range, referred to as the parabolic-drag region, the variation of drag with C_L^2 is linear (see sketch (a)).

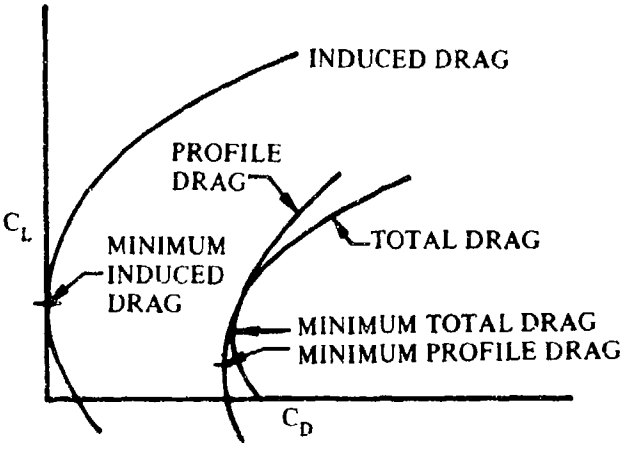


SKETCH (a)

Above C_{L_c} the polar breaks away from a simple parabolic representation because of separation effects, which cause the drag to increase significantly and the drag polar to deviate considerably from the parabolic-drag variation. High sweepback and sharp leading edges promote leading-edge separation at relatively low lift coefficients, resulting in low values of the "critical" lift coefficient.

Cambered and/or twisted wings have a somewhat more complicated drag characteristic. Neither the minimum profile drag nor the minimum induced drag necessarily occurs at zero lift. Sketch (b) illustrates these drag components for a typical cambered and twisted wing. Furthermore, the span-efficiency factor, at any given lift coefficient, varies within wide limits for these wings.

SKETCH (b)



In supersonic flow the wing drag-due-to-lift breakdown is similar to that described above. In addition to the induced drag resulting from the trailing-vortex system (sweptback at the Mach angle), there exists shock-wave drag due to lift resulting from the viscous dissipation associated with the shock waves.

A. SUBSONIC

Many attempts have been made to develop empirical methods for predicting the subsonic span-efficiency factor over the parabolic-drag region. Three recent attempts are reported in references 1, 2, and 3. Frost and Rutherford (reference 1) have used a measure of leading-edge suction as a function of the leading-edge-radius Reynolds number to correlate e based on equation 4.1.5.2-e. This correlation has been further refined in reference 2 to account for planform geometry. In reference 3, Gardner and Weir take a more basic approach to the problem by correlating the viscous drag due to lift as a function of streamwise-thickness ratio and the loss in lift-curve slope due to viscosity. The empirical results of reference 3 are used as the basis of the method presented in reference 4 for estimating the viscous drag due to lift.

At subsonic speeds methods are presented for determining the drag due to lift of the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal wings)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

These general categories of non-straight-tapered wings are illustrated in sketch (a) of Section 4.1.3.2. Their wing-geometry parameters are presented in Section 2.2.2.

Straight-Tapered Wings

This method is based on the empirical correlation of the span-efficiency factor as a function of leading-edge suction as presented in reference 1. This correlation is further refined in reference 2 to account for planform geometry. The effect of linear wing twist on the subsonic inviscid induced drag of swept wings is accounted for by the methods of reference 5.

The subsonic drag due to lift of twisted, sweptback wings of straight-tapered planform for lift coefficients up to the "critical" lift coefficient is given by

$$C_{D_L} = \frac{C_L^2}{\pi A e} + C_L \theta \; c_{\ell_\alpha} v + \left(\theta \; c_{\ell_\alpha}\right)^2 \; w \qquad \text{4.1.5.2-h}$$

where

C_L is the wing lift coefficient.

c_{ℓ_α} is the airfoil section lift-curve slope (2π per radian is sufficiently accurate for this method.)

θ is the wing twist, positive for washin (a linear twist distribution is assumed).

v is the induced-drag factor due to linear twist obtained from figures 4.1.5.2-42a through 4.1.5.2-42i.

w is the zero-lift drag factor due to linear twist obtained from figures 4.1.5.2-48a through 4.1.5.2-48i.

e is the span-efficiency factor determined by

$$e = \frac{1.1\left(C_{L_\alpha}/A\right)}{R\left(C_{L_\alpha}/A\right) + (1 - R)\pi} \qquad \text{4.1.5.2-i}$$

where

C_{L_α} is the wing lift-curve slope obtained by the method presented for straight-tapered wings in paragraph A of Section 4.1.3.2.

R is the leading-edge-suction parameter defined as the ratio of leading-edge suction actually attained to that theoretically possible. This parameter is presented in figure 4.1.5.2-53 as a function of leading-edge-radius Reynolds number, Mach number, aspect ratio, and sweepback. The leading-edge-radius Reynolds number $R_{\ell_{LER}}$ is based on the leading-edge radius of the airfoil at the wing mean aerodynamic chord.

For values of the parameter $R_{\ell_{LER}} \cot \Lambda_{LE} \sqrt{1 - M^2 \cos^2 \Lambda_{LE}} > 1.3 \times 10^5$, R is read from figure 4.1.5.2-53b.

For wings with sharp leading edges $R_{\ell_{LER}} = 0$ and $R = 0$. For such configurations the method results in the approximation $C_{D_L}/C_L^2 = 1/(1.1\, C_{L_\alpha})$.

A comparison of test data with results calculated by this method is presented as table 4.1.5.2-A. Most of the configurations listed in the table are wing-body combinations with small values of the ratio of body diameter to wing span. For these configurations, the predictions were made using the total wing planform geometry and neglecting body effects. The ranges of planform and flow parameters of the test data are:

$$2 \leqslant A \leqslant 10.7$$
$$0 \leqslant \lambda \leqslant 0.713$$
$$19.1^\circ \leqslant \Lambda_{LE} \leqslant 63.4^\circ$$
$$0.72 \times 10^6 \leqslant R_{\ell_{MAC}} \leqslant 16.6 \times 10^6$$
$$0.13 \leqslant M \leqslant 0.81$$

Since the effect of camber is not accounted for in the method, no cambered wing data are included in table 4.1.5.2-A.

The limited amount of data available precludes substantiation of the effect of linear wing twist as given in reference 5. The design charts for the induced-drag factor due to linear twist and the zero-lift drag factor due to linear twist have resulted from the use of 59 Weissinger span stations to compute these quantities by means of an automatic digital computer program. In addition, the effect of compressibility on these parameters has been accounted for by applying the Prandtl-Glauert transformation.

Application of the method to an untwisted, sweptback wing is illustrated by sample problem 1 on page 4.1.5.2-9.

Non-Straight-Tapered Wings

Semiempirical methods, taken from reference 2, are presented for estimating the subsonic induced drag of non-straight-tapered wings. The methods presented for double-delta and curved planforms are applicable only to wings with sharp leading edges. In the development of these methods the effect of leading-edge suction was neglected, and the expression used as a basis for the correlation of induced drag was written solely in terms of the normal-force coefficient.

The method presented for cranked planforms is applicable only to wings with round leading edges. All the cranked wings analyzed in reference 2 had round leading edges; therefore, the development of the prediction technique was based on properly accounting for the leading-edge suction force. The resulting method is an extension of the straight-tapered-wing method presented above. It was assumed that given an accurate estimate of the leading-edge-suction parameter on both the inboard and outboard panels of a cranked wing, an effective leading-edge-suction parameter can be estimated by a span-weighted average.

The method presented for cranked wings is applicable in the higher lift-coefficient range where the drag polar deviates from a parabolic variation, as well as in the lower lift-coefficient range. The method presented for sharp-edged double-delta and curved planforms is valid only for the higher lift coefficients. In each case an empirical correlation has been derived that accounts for the effects of flow separation at the higher values of lift coefficient.

Double-Delta Wings

The subsonic induced drag of double-delta wings with sharp leading edges is given by

$$C_{D_L} = 0.95\, C_L \tan\alpha \qquad 4.1.5.2\text{-j}$$

where

C_L is the wing lift coefficient at angle of attack obtained by the method presented for double-delta wings in paragraph A of Section 4.1.3.3.

The constant in equation 4.1.5.2-j is the drag-due-to-lift factor. This factor has been determined during the course of the work reported in reference 2 by plotting test values of $C_{D_L}/(C_L \tan\alpha)$ versus α. This correlation showed that at $\alpha > 8^o$, the ratio of $C_{D_L}/(C_L \tan\alpha)$ approaches 0.95. However, below $\alpha = 8^o$ there was considerable scatter in the data. This is attributed to the inability to determine C_{D_L} accurately from the test data at the lower angles of attack. The method should not be expected to give satisfactory results below $\alpha = 8^o$.

A sample problem illustrating the use of this method is presented on page 4.1.5.2-10.

A comparison of test data with results calculated by this method is presented as table 4.1.5.2-B (taken from reference 2). The test results have been compiled entirely from reference 15 and were the only available low-speed data for sharp-edged double-delta wings. Although all the configurations listed in the table are wing-body combinations, all predictions were made by using the total wing planform geometry and neglecting body effects. Note that at $\alpha = 4^o$ the method does not adequately predict C_{D_L} for sharp-edged double-delta wings.

Since all the test data of table 4.1.5.2-B were included in the drag-due-to-lift-factor correlation, application of the method to configurations with geometric parameters falling outside those of table 4.1.5.2-B should be approached with caution. The ranges of planform parameters used in the correlation are:

$$1.34 \leq A \leq 1.87$$
$$72.6^o \leq \Lambda_{LE_i} \leq 77.4^o$$
$$\Lambda_{LE_o} = 59^o$$
$$0.332 \leq \eta_B \leq 0.628$$

Although the data in table 4.1.5.2-B are for $M = 0.13$, the method should be applicable at higher subsonic Mach numbers, provided an accurate estimation of the C_L versus α variation can be made.

The effects of wing twist and/or camber are not accounted for in the method.

For double-delta wings with round leading edges, it is suggested that the subsonic drag due to lift be approximated by using the method for cranked wings.

Cranked Wings

The subsonic drag due to lift of cranked wings with round leading edges is given by

$$C_{D_L} = \frac{C_L^2}{\pi Ae} + \Delta C_{D_L} \qquad 4.1.5.2\text{-k}$$

where

C_L is the wing lift coefficient.

ΔC_{D_L} is that portion of the drag due to lift resulting from a breakdown in the leading-edge suction at lift coefficients above the parabolic-drag-polar region. An empirical correlation of ΔC_{D_L} as a function of lift coefficient and aspect ratio is presented as figure 4.1.5.2-54.

e is the span-efficiency factor over the parabolic-drag region, given by

$$e = \frac{C_{L_\alpha}/A}{R'\left(C_{L_\alpha}/A\right) + (1 - R')\,\pi} \qquad 4.1.5.2\text{-}\ell$$

where

C_{L_α} is the wing lift-curve slope obtained by the method presented for cranked wings in paragraph A of Section 4.1.3.2.

R' is the effective leading-edge-suction parameter given by

$$R' = R_i(\eta_B) + R_o(1 - \eta_B) \qquad 4.1.5.2\text{-m}$$

where

R_i is the leading-edge suction parameter of the inboard panel, obtained from figure 4.1.5.2-53, but with the parameter $A\lambda/\cos\Lambda_{LE} = 0$.

R_o is the leading-edge-suction parameter of the outboard panel, obtained from figure 4.1.5.2-53 by assuming the outboard panels to be an isolated wing.

The leading-edge-radius Reynolds numbers required to read R_i and R_o from figure 4.1.5.2-53 are based on the leading-edge radius of the mean aerodynamic chord of the inboard and outboard panels, respectively. For values of the parameter $R_{\ell_{LER}} \cot\Lambda_{LE}\sqrt{1 - M^2\cos^2\Lambda_{LE}} > 1.3 \times 10^5$, R_i and/or R_o are read from figure 4.1.5.2-53b.

A sample problem illustrating the use of this method is presented on page 4.1.5.2-11.

A comparison of test data with results calculated by this method is presented as tables 4.1.5.2-C and 4.1.5.2-D (both taken from reference 2). Table 4.1.5.2-C compares the parabolic drag-due-to-lift factor $C_{D_L}/C_L^2 = 1/(\pi Ae)$ with test data. Table 4.1.5.2-D compares the drag due to lift over the nonparabolic region of the drag polar with test data. In table 4.1.5.2-D only the calculated results for references 16 and 18 are based on the predicted value of the parabolic drag-due-to-lift factor. The remainder of the data used the test value of C_{D_L}/C_L^2 combined with ΔC_{D_L} from figure 4.1.5.2-54.

Where test data were available for wing-body configurations, the portion of the inboard panel submerged in the body was accounted for in calculating the parabolic drag due to lift. This was accomplished by defining the effective leading-edge-suction parameter by

$$R' = R_i\left(\eta_B - \frac{d}{b}\right) + R_o(1 - \eta_B) \qquad 4.1.5.2\text{-m}'$$

and basing the leading-edge-radius Reynolds number used to obtain R_i on the leading-edge radius of the mean aerodynamic chord of the exposed inboard panel.

The effect of Reynolds number on the accuracy of predicting ΔC_{D_L} cannot be assessed quantitatively, since all the data used in the empirical correlation were for low Reynolds numbers except those from reference 22. Although a comparison of the data of reference 22 with the low Reynolds-number data shows no effect of Reynolds number, it must be expected that Reynolds number will affect ΔC_{D_L}.

The effect of wing twist is not accounted for in the method. The test data include cambered-wing data, and camber seems to have no effect on ΔC_{D_L}; however, there are not enough data to allow a quantitative evaluation of camber effects.

Finally, it should be pointed out that all the test data of table 4.1.5.2-D were used to derive the ΔC_{D_L} correlation. Therefore, no independent evaluation of the accuracy of the method in the nonparabolic region has been accomplished. In view of this, figure 4.1.5.2-54 should be used with caution outside the range of planform parameters used in the correlation (see figure 4.1.5.2-54).

Curved Wings

The correlation of $C_{D_L}/(C_L \tan \alpha)$, of reference 2, for determining the drag-due-to-lift factor of double-delta wings with sharp leading edges also included data on both Gothic and ogee wings at Mach numbers from 0.1 to 0.7. Therefore, the prediction method is essentially the same as that for double-delta wings.

As previously noted, the correlation for the drag-due-to-lift factor showed considerable scatter in the data below $\alpha = 8^\circ$. Although the data scatter for the curved planforms was not as widely dispersed as that for the double-delta planforms, the method should not be expected to give satisfactory results below $\alpha = 8^\circ$.

The subsonic drag due to lift of curved wings with sharp leading edges is given by equation 4.1.5.2-j; i.e.,

$$C_{D_L} = 0.95\, C_L \tan \alpha$$

where C_L is the wing lift coefficient at angle of attack obtained by the method presented for curved wings in paragraph A of Section 4.1.3.3.

A sample problem illustrating the use of this method is presented on page 4.1.5.2-13.

A comparison of test data with results calculated by this method is presented as table 4.1.5.2-E (taken from reference 2). The test data are for two thin Gothic and two thin ogee wings. It is noted that the calculated results below $\alpha = 8^\circ$ compare more favorably with the test data than those for double-delta wings at low angles of attack. However, since no consistent trend is indicated by the comparison at the lower angles of attack, there is no basis for lowering the angle-of-attack limit below 8°

Since all the data are for low Reynolds numbers, the effect of Reynolds number cannot be assessed. However, it is expected that Reynolds number will affect the results even at low lift coefficients, since leading-edge separation is almost immediate for the sharp-nosed airfoils.

Since all the test data of table 4.1.5.2-E were included in the drag-due-to-lift-factor correlation, application of the method to configurations with geometric parameters falling outside those of table 4.1.5.2-E should be approached with caution. The ranges of planform parameters used in the correlation are:

$$0.75 \leq A \leq 1.98$$

$$0.455 \leq p \leq 0.667$$

$$0.250 \leq \frac{b_W}{2\ell} \leq 0.450$$

The method is limited to thin wings ($t/c < 0.06$). Tests on one 12-percent thick Gothic wing showed less drag due to lift than did the tests on the thin wings. This is attributed to the development of significant suction forces on the forward-facing slopes of the thick wing. The correlation of $C_{D_L}/(C_L \tan\alpha)$ for the 12-percent-thick wing resulted in a constant drag-due-to-lift factor of 0.87.

The effects of wing twist and/or camber are not accounted for in the method.

Sample Problems

1. Conventional, Straight-Tapered Wing

Given: The sweptback wing of reference 14.

Wing Characteristics:

$A = 5.14$ $\lambda = 0.713$ $\Lambda_{LE} = 36.2^o$ $\Lambda_{c/2} = 33.7^o$ $\bar{c} = 1.166$ ft

NACA 65_1A012 airfoil LER = 0.00922c No twist

Additional Characteristics:

$M = 0.75; \beta = 0.661$ $R_{\ell_{MAC}} = 2 \times 10^6$ $R_{\ell_{LER}} = 18.4 \times 10^3$

$\kappa = 1.0$ (assumed)

Compute:

Leading-edge-suction parameter

$$R_{\ell_{LER}} \cot \Lambda_{LE} \sqrt{1 - M^2 \cos^2 \Lambda_{LE}} = (18.4 \times 10^3)(1.3663)\sqrt{1 - (0.75)^2(0.8070)^2} = 20.0 \times 10^3$$

$$\frac{A\lambda}{\cos \Lambda_{LE}} = \frac{(5.14)(0.713)}{(0.8070)} = 4.54$$

$R = 0.803$ (figure 4.1.5.2-53)

$$\frac{A}{\kappa}\sqrt{\beta^2 + \tan^2 \Lambda_{c/2}} = \frac{5.14}{1}\sqrt{(0.661)^2 + (0.6675)^2} = 4.83$$

$$\frac{C_{L_\alpha}}{A} = 0.870 \quad \text{(figure 4.1.3.2-49)}$$

Span-efficiency factor

$$e = \frac{1.1\left(C_{L_\alpha}/A\right)}{R\left(C_{L_\alpha}/A\right) + (1 - R)\,\pi} \qquad \text{(equation 4.1.5.2-i)}$$

$$= \frac{(1.1)\,(0.870)}{(0.803)\,(0.870) + (1 - 0.803)\,\pi} = 0.726$$

Solution:

$$C_{D_L} = \frac{C_L{}^2}{\pi Ae} \qquad \text{(equation 4.1.5.2-h)}$$

$$\frac{C_{D_L}}{C_L{}^2} = \frac{1}{\pi Ae} = \frac{1}{\pi\,(5.14)\,(0.726)} = 0.085$$

This compares with a test value of 0.090 from reference 14.

2. Double-Delta Wing

Given: A double-delta planform of reference 15.

Wing Characteristics:

$A_W = 1.73$ $A_i = 0.409$ $S_W = 560.0$ sq ft $S_i = 407.0$ sq ft

$S_o = 153.0$ sq ft $\Lambda_{LE_i} = 77.4^o$ $\Lambda_{LE_o} = 59^o$ $\Lambda_{TE} = -10^o$

$\eta_B = 0.414$

Additional Characteristics:

$M = 0.13$

Compute:

Variation of C_L with α (Section 4.1.3.3)

The predicted values of C_L versus α for this configuration are listed in table 4.1.3.3-B (This configuration is shown under "reference 31" of the table)

Solution:

$C_{D_L} = 0.95\ C_L \tan \alpha$ (equation 4.1.5.2-j)

α (deg)	C_L table 4.1.3.3-B	tan α	C_{D_L} eq. 4.1.5.2-j
4	0.143	0.0699	0.00950
8	0.302	0.1405	0.04031
12	0.491	0.2126	0.09917
16	0.685	0.2867	0.1866
20	0.974	0.3640	0.3368

The calculated results are compared with test values in table 4.1.5.2-B.

3. Cranked Wing

Given: The cranked wing-body configuration of reference 16. This is the configuration of the cranked-wing sample problem of paragraph A of Section 4.1.3.2.

Wing Characteristics:

$A_W = 4.0$ $A_o = 2.37$ $\Lambda_{LE_i} = 48.6^o$ $\Lambda_{LE_o} = 7.7^o$

$\lambda_o = 0.517$ $\eta_B = 0.60$ NACA 65A006 airfoil LER = 0.00229c

$\bar{c}_i = 0.933$ ft $\bar{c}_o = 0.525$ ft

Additional Characteristics:

$M = 0.80$ $R_\ell = 3.645 \times 10^6$ per ft $\frac{d}{b} = 0.139$

Compute:

Leading-edge-suction parameters, R_i and R_o

Inboard panel:

$$\left(R_{\ell_{LER}}\right)_i = (3.645 \times 10^6)(0.00229\,\bar{c}_i) = (3.645 \times 10^6)(0.00229)(0.933) = 7.79 \times 10^3$$

$$\left(R_{\ell_{LER}} \cot \Lambda_{LE} \sqrt{1 - M^2 \cos^2 \Lambda_{LE}}\right)_i = (7.79 \times 10^3)(0.8816)\sqrt{1 - (0.8)^2 (0.6613)^2}$$

$$= 5.83 \times 10^3$$

$R_i = 0.470$ (figure 4.1.5.2-53, with $\left(A\lambda/\cos \Lambda_{LE}\right)_i = 0$. See definition of R_i, page 4.1.5.2-7)

Outboard panel:

$$\left(R_{\ell_{LER}}\right)_o = (3.645 \times 10^6)(0.00229\,\bar{c}_o) = (3.645 \times 10^6)(0.00229)(0.525) = 4.38 \times 10^3$$

$$\left(R_{\ell_{LER}} \cot \Lambda_{LE} \sqrt{1 - M^2 \cos^2 \Lambda_{LE}}\right)_o = (4.38 \times 10^3)(7.396)\sqrt{1 - (0.8)^2 (0.9910)^2}$$

$$= 1.973 \times 10^4$$

$$\left(\frac{A\lambda}{\cos \Lambda_{LE}}\right)_o = \frac{(2.37)(0.517)}{0.9910} = 1.236$$

$R_o = 0.766$ (figure 4.1.5.2-53)

Effective leading-edge-suction factor

$$R' = R_i\left(\eta_B - \frac{d}{b}\right) + R_o\,(1 - \eta_B) \qquad \text{(equation 4.1.5.2-m')}$$

$$= (0.470)(0.60 - 0.139) + (0.766)(1 - 0.60)$$

$$= 0.523$$

C_{L_α}/A = 1.081 per rad (sample problem, paragraph A, Section 4.1.3.2)

Span-efficiency factor over parabolic-drag region

$$e = \frac{C_{L_\alpha}/A}{R'(C_{L_\alpha}/A) + (1 - R')\pi} \qquad \text{(equation 4.1.5.2-l)}$$

$$= \frac{1.081}{(0.523)(1.081) + (1 - 0.523)\pi}$$

$$= 0.524$$

$$\frac{C_{D_L}}{C_L^2} = \frac{1}{\pi Ae} = \frac{1}{\pi (4.0)(0.524)} = 0.152$$

Solution:

$$C_{D_L} = \frac{C_L^2}{\pi Ae} + \Delta C_{D_L} \qquad \text{(equation 4.1.5.2-k)}$$

$$= \frac{C_{D_L}}{C_L^2} C_L^2 + \Delta C_{D_L}$$

①	②	③	④	⑤	⑥
C_L	C_L/A ①/ 4	ΔC_{D_L} fig 4.1.5.2-54	$\frac{C_{D_L}}{C_L^2}$	$\frac{C_{D_L}}{C_L^2} C_L^2$ ④①^2	C_{D_L} eq 4.1.5.2-k ⑤ + ③

0.7	0.175	0.0840		0.0745	0.1585
0.8	0.200	0.1245		0.0973	0.2218

The test values for this configuration are presented in tables 4.1.5.2-C and 4.1.5.2-D for the cranked wing mounted on a circular-ogive body. The calculated results presented in tables 4.1.5.2-C and 4.1.5.2-D take into account the portion of the inboard panel submerged in the body by applying the corrections noted on page 4.1.5.2-7. The leading-edge-radius Reynolds number used to obtain R_i is based on the leading-edge radius of the mean aerodynamic chord of the exposed inboard panel, and the effective leading-edge-suction parameter is determined by using equation 4.1.5.2-m'.

4. Curved Wing

Given: The ogee wing of reference 23. This is the same configuration as the curved-wing sample problem of paragraph A of Section 4.1.3.3.

Wing Characteristics:

$A = 1.20$ $b = 12.0$ in. $\ell = 20.0$ in.

Additional Characteristics:

$M = 0.4$

Compute:

Variation of C_L with α (Section 4.1.3.3)

The predicted values of C_L versus α are obtained from the curved-wing sample problem of paragraph A of Section 4.1.3.3.

Solution:

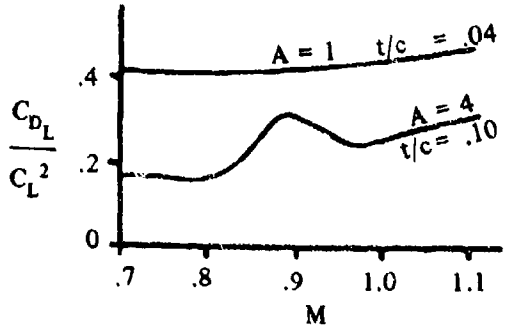
$C_{D_L} = 0.95\ C_L\ \tan\alpha$ (equation 4.1.5.2-j)

α (deg)	C_L Sec. 4.1.3.3	tan α	C_{D_L} eq. 4.1.5.2-j
4	0.136	0.0699	0.0090
8	0.288	0.1405	0.0384
12	0.465	0.2126	0.0939

The calculated results are compared with test values in table 4.1.5.2-E.

B. TRANSONIC

Test data on straight-tapered wings show that the variation of the drag-due-to-lift parameter C_{D_L}/C_L^2 with Mach number at transonic speeds is somewhat analogous to that of the lift-curve slope. That is, for thick and/or high-aspect-ratio wings this parameter experiences significant deviations with Mach number, while for thin and/or low-aspect-ratio wings this parameter varies uniformly with Mach number (see sketch (c)).



SKETCH (c)

Transonic data on non-straight-tapered wings are too few to allow quantitative analysis of the variation of drag due to lift with Mach number.

The only available approach to the estimation of transonic drag due to lift of conventional, trapezoidal wings appears to be through the use of transonic similarity parameters. This is a particularly useful approach where the quantity of data available for correlation is limited. The method presented, therefore, uses transonic similarity parameters. It should be pointed out, however, that the bulk of existing data at transonic speeds is derived from "bump tests," which are frequently questioned because of the spanwise Mach number gradients.

DATCOM METHOD

The transonic drag due to lift of conventional, trapezoidal planforms of symmetrical section may be approximated by using figures 4.1.5.2-55a through 4.1.5.2-55c for given values of the transonic similarity parameters, $A \tan \Lambda_{LE}$ and $\frac{M^2 - 1}{(t/c)^{2/3}}$

Sample Problem

Given: The following straight-tapered wing from reference 26.

$A = 4.0$ $\quad \lambda = 0$ $\quad \Lambda_{LE} = 45^o$ $\quad$ NACA 63A004 airfoil

Compute:

$(t/c)^{1/3} = 0.342$; $\quad (t/c)^{2/3} = 0.116$; $\quad A(t/c)^{1/3} = 1.368$

$A \tan \Lambda_{LE} = 4.0$

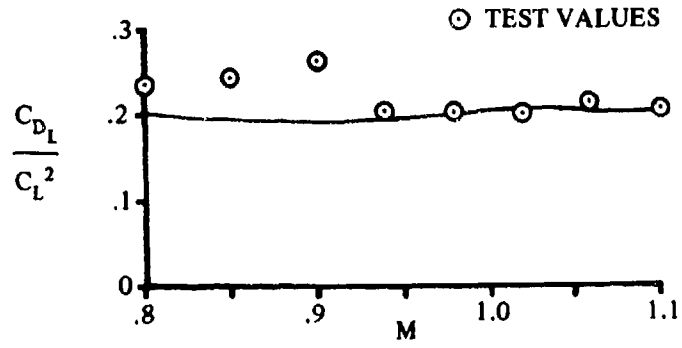
$\frac{M^2 - 1}{(t/c)^{2/3}}$ (see calculation table below)

$\left(\frac{t}{c}\right)^{-1/3}\left(\frac{C_{D_L}}{C_L^2}\right)$ (figures 4.1.5.2-55a and -55b extrapolated, see calculation table below)

Solution:

①	②	③	④
M	$\frac{M^2 - 1}{(t/c)^{2/3}}$	$\left(\frac{t}{c}\right)^{-1/3}\frac{C_{D_L}}{C_L^2}$ fig. 4.1.5.2-55	C_{D_L}/C_L^2 ③ $(t/c)^{1/3}$
0.8	-3.10	0.59	0.202
0.9	-1.64	0.57	0.195
0.94	-1.00	0.57	0.195
0.98	-0.34	0.58	0.198
1.00	0	0.60	0.205
1.05	0.88	0.60	0.205
1.10	1.81	0.59	0.202

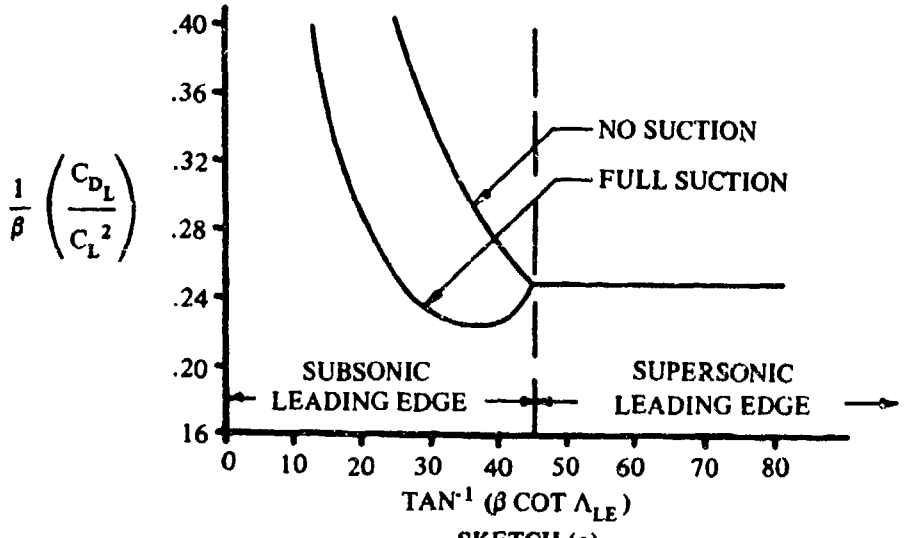
The calculated values of C_{D_L}/C_L^2 are compared with test values from reference 26 in sketch (d).



SKETCH (d)

C. SUPERSONIC

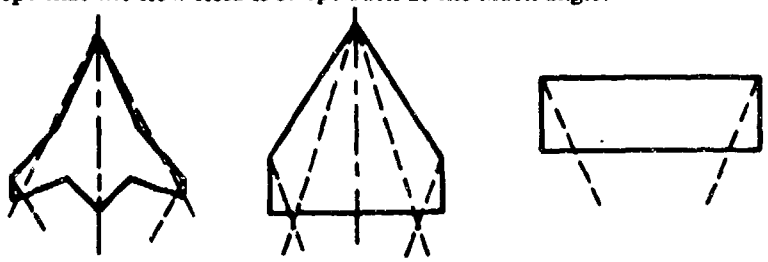
At supersonic speeds, wings are generally classified according to whether the Mach number component perpendicular to the leading edge is subsonic or supersonic. A typical presentation of supersonic drag due to lift is shown in sketch (e). For supersonic-leading-edge wings, certain regions of the wing will be in two-dimensional flow where the spanwise pressure loading on the surface is constant.



SKETCH (e)

Other portions of the wing are influenced by tip effects and by the wing apex. Three cases are shown in sketch (f). The two-dimensional region has wave drag due to lift, which can be calculated by simple linear theory or by shock-expansion theory. But because the span loading is constant, this region does not produce any vortex drag. The three-dimensional region has shock-wave drag due to lift, but not as much as that of the two-dimensional region. The three-dimensional region also has a drag-due-to-lift contribution associated with the vortex that is shed because of the varying span loading. This phenomenon is exactly like its subsonic counterpart except that the flow field is swept back at the Mach angle.

SKETCH (f)



In general, the drag due to lift of a wing quickly approaches the two-dimensional value as the leading edge progresses from the sonic into the supersonic region. The two-dimensional value from linear theory is

$$C_{D_L} = \frac{\beta C_L^2}{4}$$

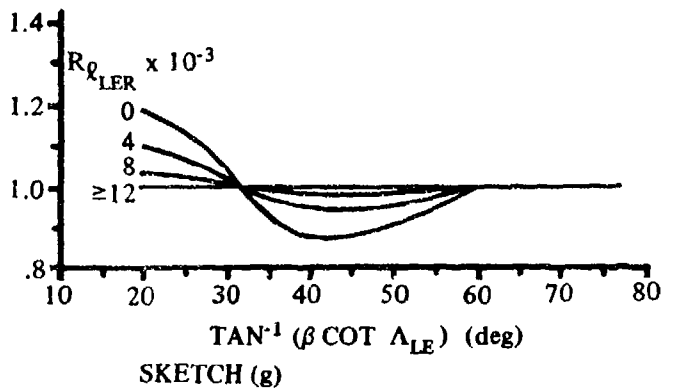
For subsonic leading edges, no part of the wing is in two-dimensional flow and the span pressure loading, in general, varies continuously across the span. Wave drag due to lift and vortex drag exist as for the supersonic leading-edge case. However, an additional phenomenon occurs. The subsonic Mach number component perpendicular to the leading edge allows leading-edge-suction pressures to develop similar to those that occur on wings in subsonic flow. These suction pressures can cause significant reductions in drag, which, to date, cannot be predicted for a given wing. The amount of suction depends upon the leading-edge shape and the wing-camber shape and distribution. Several authors have, however, calculated the maximum amount of suction attainable for several types of wings (e.g., references 6 and 7). Camber can also produce a significant drag-due-to-lift reduction that is not affected by leading-edge suction. Sketch (e) above shows typical drag reduction due to suction for a cambered delta wing.

Test results for subsonic leading-edge wings generally fall between the limits of wings with no leading-edge suction and wings with full leading-edge suction. For a given test on a cambered wing, however, it is impossible to determine what fraction of the drag reduction is attributable to camber, since camber and leading-edge-suction effects are very similar in nature.

For conditions where the leading edge is slightly supersonic, the theoretical results for cambered wings are less than the two-dimensional value because the forward inclination of the integrated force vector due to the pressures on the cambered portion of the wing persists into the supersonic leading-edge region. In practice, uncambered wings of finite thickness exhibit the same trend, because the leading-edge shock is detached and causes the leading edge to operate at a lower effective Mach number; that is, the airfoil operates at a subsonic leading-edge condition where leading-edge suction can reduce the drag even though the theoretical leading-edge condition is supersonic.

The Reynolds number based on leading-edge radius can also significantly affect the drag due to lift. At low Reynolds number, local leading-edge flow separation can occur with a loss in leading-edge suction. Low Reynolds number also affects the boundary-layer transition point on the wing. In general, increasing Reynolds number causes an increase in friction drag at low angles of attack (forward-moving transition point) and no change in friction drag at high angles of attack (transition point is already forward). Sketch (g) shows the effect of leading-edge-radius Reynolds number based on test data (reference 8). The ordinate of this sketch is the ratio of the induced-drag parameter C_{D_L}/C_L^2 at a Reynolds number of 14×10^3 based on leading-edge radius to the value of the parameter at a given value of leading-edge Reynolds number.

$$\frac{\left(\frac{C_{D_L}}{C_L^2}\right)_{R_{\ell_{LER}} = 14 \times 10^3}}{\left(\frac{C_{D_L}}{C_L^2}\right)_{R_{\ell_{LER}} = \text{Test Value}}}$$



SKETCH (g)

Methods are presented for determining the wing drag due to lift over the parabolic-drag region for the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal wings)

Non-Straight-Tapered Wings
- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

These three general categories of non-straight-tapered wings are illustrated in sketch (a) of Section 4.1.3.2. Their wing-geometry parameters are presented in Section 2.2.2.

The methods presented are based on the conclusions of an analysis of the experimental results of the drag due to lift of slender uncambered wings at supersonic speeds reported in reference 9. It was shown therein that the drag-due-to-lift factor at supersonic speeds collapses into a fairly well-defined single curve when plotted as a function of the wing planform shape and slenderness parameters.

The supersonic design chart presented for non-straight-tapered wings is taken from reference 2, and the parameters used to collapse the data are modifications of those presented in reference 9. The correlation makes no distinction between round and sharp leading edges nor between cambered and uncambered wings.

The parameters used to collapse the data for non-straight-tapered wings in reference 2 have also been applied to uncambered straight-tapered wings. The resulting correlation showed a distinction between straight-tapered wings with round leading edges and those with sharp leading edges.

DATCOM METHODS

Straight-Tapered Wings

The supersonic drag due to lift over the parabolic-drag region for straight-tapered wings is obtained using the procedure outlined in the following steps:

Step 1. Using the given wing geometry, calculate the aspect ratio, the planform shape parameter p, and the wing slenderness parameter $\frac{b_W}{\ell}$. (See Section 2.2.2 for wing-geometry parameters).

Step 2. At the desired value of $\frac{\beta b_W}{2\ell}$ obtain $\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p}$ from the proper design curve of figure 4.1.5.2-58.

Step 3. Calculate the drag due to lift by

$$\frac{C_{D_L}}{C_L^2} = \left[\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p}\right]\left(\frac{1}{\pi A}\right)\left(\frac{1+p}{p}\right) \qquad 4.1.5.2\text{-n}$$

A comparison of test data with results calculated by this method is presented as table 4.1.5.2-F. With one exception, all the configurations listed in the table are wing-body combinations with small ratios of body diameter to wing span. The calculations for these configurations were made by using the theoretical planform extended to the body center line and neglecting body effects. The test configurations are about equally divided between wings with sharp leading edges and those with round leading edges. None of the wings are cambered. The ranges of the planform parameters covered for each leading-edge shape are:

Round Leading Edge	Sharp Leading Edge
$1.313 \leq A \leq 4.0$	$1.5 \leq A \leq 3.5$
$35^{o} \leq \Lambda_{LE} \leq 73^{o}$	$0 \leq \Lambda_{LE} \leq 71^{o}$
$0 \leq \lambda \leq 0.5$	$0 \leq \lambda \leq 1.0$
$0.237 \leq p \leq 0.502$	$0.333 \leq p \leq 0.995$
$0.271 \leq \frac{b_W}{2\ell} \leq 1.00$	$0.333 \leq \frac{b_W}{2\ell} \leq 1.070$

The sample problem presented on page 4.1.5.2-20 for a double-delta wing illustrates the application of the straight-tapered-wing method.

Non-Straight-Tapered Wings

The supersonic drag due to lift over the parabolic-drag region for non-straight-tapered wings is obtained by following the procedure outlined above for straight-tapered wings. The value of the parameter $\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p}$ at the desired value of $\frac{\beta b_W}{2\ell}$ is obtained from figure 4.1.5.2-59. This correlation makes no distinction between wing planforms, between round and sharp leading edges, nor between cambered and uncambered wings.

A comparison of test data with results calculated by this method is presented in table 4.1.5.2-G for double-delta and cranked wings, and in table 4.1.5.2-H (taken from reference 2) for curved wings.

All the configurations listed in table 4.1.5.2-G are wing-body combinations with small ratios of body diameter to wing span. The calculations for these configurations were made by using the theoretical planform extended to the body center line and neglecting body effects. The table includes double-delta wings with both round and sharp leading edges and cranked wings with round leading edges. Some of the wings with round leading edges are cambered. The ranges of the planform parameters of the test data are:

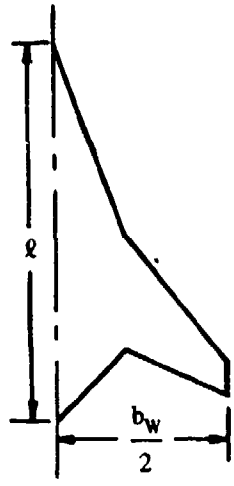
Double-Delta Wings	Cranked Wings
$1.74 \leq A \leq 3.15$	$2.91 \leq A \leq 4.0$
$0.292 \leq p \leq 0.500$	$0.491 \leq p \leq 0.666$
$0.353 \leq \frac{b_W}{2\ell} \leq 0.787$	$0.710 \leq \frac{b_W}{2\ell} \leq 1.333$

The results presented in table 4.1.5.2-H for curved wings with sharp leading edges agree quite well with test data. This is probably due to the fact that the curved planforms have a more limited range of geometric parameters than the double-delta and cranked wings. The ranges of planform parameters of the test data are:

$$0.75 \leq A \leq 1.39$$
$$0.384 \leq p \leq 0.667$$
$$0.208 \leq \frac{b_W}{2\ell} \leq 0.389$$

Sample Problem

Given: The double-delta wing of reference 30 designated X-67-67.



Wing Characteristics:

$A = 2.42$ $\quad S_W = 1.651$ sq ft

$b_W = 2.0$ ft $\quad \ell = 2.22$ ft

Additional Characteristics:

$M = 2.01$; $\quad \beta = 1.742$

Compute:

$$\frac{b_W}{2\ell} = \frac{2.0}{(2)(2.22)} = 0.450$$

$$\frac{\beta b_W}{2\ell} = (1.742)(0.450) = 0.784$$

$$p = \frac{S_W}{b_W \ell} = \frac{1.651}{(2.0)(2.22)} = 0.372$$

$$\frac{1+p}{p} = \frac{1+0.372}{0.372} = 3.688$$

$$\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p} = 0.961 \qquad \text{(figure 4.1.5.2-59)}$$

Solution:

$$\frac{C_{D_L}}{C_L^2} = \left[\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p}\right] \left(\frac{1}{\pi A}\right)\left(\frac{1+p}{p}\right) \qquad \text{(equation 4.1.5.2-n)}$$

$$= (0.961)\left(\frac{1}{2.42\pi}\right)(3.688) = 0.466$$

This compares with a test value of 0.479 from reference 30.

4.2 BODIES AT ANGLE OF ATTACK

4.2.1 BODY LIFT

4.2.1.1 BODY LIFT-CURVE SLOPE

A. SUBSONIC

One of the first attempts to use potential theory for the estimation of lift for bodies of revolution was made by Munk (reference 1). Several similar methods have since been developed that give essentially the same results (references 2 and 3). Potential theory is limited to angles of attack near zero, where viscous cross-flow forces are small. At higher angles of attack the viscous forces become increasingly important (see Section 4.2.1.2).

DATCOM METHOD

The method presented for estimating the lift-curve slope of bodies of revolution at subsonic speeds uses the potential flow term of the expression for body lift from reference 4. The lift-curve slope, based on $V_B^{2/3}$, is

$$C_{L_\alpha} = \frac{2(k_2 - k_1)\, S_o}{V_B^{2/3}} \quad \text{(per radian)} \qquad 4.2.1.1\text{-a}$$

where

V_B is the total body volume.

$(k_2 - k_1)$ is the apparent mass factor developed by Munk and presented in figure 4.2.1.1-20a as a function of body fineness ratio.

S_o is the body cross-sectional area at x_o.

x_o is the body station where the flow ceases to be potential. This is a function of x_1, the body station where the parameter, dS_x/dx first reaches its maximum negative value. x_o and x_1 are correlated in figure 4.2.1.1-20b.

S_x is the body cross-sectional area at any body station.

In many cases it will be possible to determine the location of x_1 by inspection. For cases that are doubtful, the area distribution should be plotted and examined to determine the location where dS_x/dx first reaches its maximum negative value.

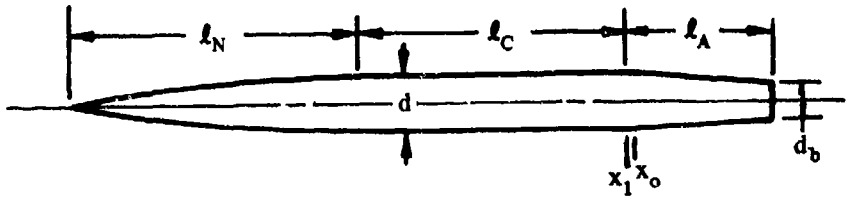
The lift-curve slopes of several bodies of revolution, calculated by this method, have been compared with test data in reference 4. In general, the accuracy of the method at angles of attack near zero is good.

For a rapid but approximate estimation, slender-body theory can be used. This gives $C_{L_\alpha} = 2$ per radian, where C_{L_α} is based on the body cross-sectional area at x_o.

No method is available for estimating the lift-curve slope of a body of noncircular cross section. Consequently, test data must be relied upon as the basis for predicting the lift-curve slope of such configurations. A summary of available test data on bodies of noncircular cross section at subsonic speeds is presented as table 4.2.1.1-A.

Sample Problem

Given: An ogive-cylinder-boattailed body of revolution of reference 18.



$d = 0.417$ ft $\quad \ell_N = 2.19$ ft $\quad \ell_C = 1.98$ ft $\quad \ell_A = 1.12$ ft

$\ell_B = 5.29$ ft $\quad f = \frac{\ell_B}{d} = 12.7 \quad V_B = 0.537$ cu ft

$x_1 = 4.17$ ft (determined by inspection) $\quad d_b = 0.275$ ft

Compute:

$x_1/\ell_B = 4.17/5.29 = 0.788$

$x_o/\ell_B = 0.793$ (figure 4.2.1.1-20b)

$x_o = (0.793)(5.29) = 4.195$ ft

$(k_2 - k_1) = 0.96$ (figure 4.2.1.1-20a)

$S_o = 0.134$ sq ft

$V_B^{2/3} = 0.537^{2/3} = 0.660$

Solution:

$$C_{L_\alpha} = \frac{2(k_2 - k_1) S_o}{V_B^{2/3}} \quad \text{(equation 4.2.1.1-a)}$$

$$= \frac{2(0.96)(0.134)}{0.660}$$

$= 0.390$ per rad (based on $V_B^{2/3}$)

This compares with a test value of 0.378 per radian, based on $V_B^{2/3}$, from reference 18. The slender-body-theory approximation gives C_{L_α} = 0.406 per radian, based on $V_B^{2/3}$.

B. TRANSONIC

Slender-body theory states that body force characteristics are not functions of Mach number. Experimental data substantially verify this result (references 5, 6, and 7). Any differences in the subsonic value of C_{L_α} obtained from paragraph A and the supersonic value of C_{L_α} obtained from paragraph C should be faired out smoothly in the transonic range.

Transonic test data on bodies of noncircular cross section are available in references 25, 26, and 5 (see table 4.2.1.1-A).

C. SUPERSONIC

Several theoretical methods that have been developed for estimating the lift-curve slope of bodies of revolution are best applied by machine methods. Three of the methods that can be used to estimate characteristics of simple nose-cylinder bodies of revolution at small angles of attack throughout the supersonic range are briefly discussed. They are the slender-body, hybrid, and second-order shock-expansion theories.

Slender-body theory is based on the assumption that the body surface slope (relative to the free stream) is everywhere so small that the boundary conditions may be applied on the axis. This condition is met if β/f_N is small, i.e., if the nose has a large fineness ratio or if the flow is close to sonic speed. Slender-body theory is applicable in the range of values of the parameter β/f_N from 0 to approximately 0.05. Hybrid theory (reference 8), a combination of a second-order axial solution with a first-order cross-flow solution, is applicable for values of β/f_N from approximately 0.05 to 0.40. The second-order shock-expansion method (reference 9), an extension of the general shock-expansion method at small angles of attack, is applicable for values of β/f_N from approximately 0.40 to ∞.

The flow around bodies with boattails can be calculated by Van Dyke's hybrid theory (reference 8). Reference 10 presents a generalized curve for estimating the normal-force-curve slope of boattails, based on the method of reference 8. Lavender and Deep (reference 11) give methods, based on the work of reference 9, for determining the normal-force-curve slope of cone-cylinder-frustums, cone-cylinder-frustum-boosters, and cone-frustum-boosters.

DATCOM METHOD

Empirical design charts are presented for estimating the normal-force-curve slope of bodies of revolution composed of ogival or conical noses and cylindrical afterbodies. In addition, theoretical results are presented for determining the increment in normal-force-curve slope due to the addition of either a boattailed or a flared body of revolution at the end of semi-infinite cylindrical bodies.

Figures 4.2.1.1-21a and 4.2.1.1-21b present C_{N_α}, based on maximum frontal area, for bodies with ogival and conical noses, respectively, and cylindrical afterbodies of varying fineness ratio. The normal-force-curve slopes of two other common nose shapes, the 3/4-power nose and the parabolic nose (1/2-power nose), are not presented directly. However, experimental data indicate that the force characteristics of cones and 3/4-power noses are similar, as are those of ogives and parabolic noses (reference 12). Tests also indicate that the addition of a cylindrical afterbody results in approximately the same increase in lift, irrespective of nose profile shape (reference 13). Therefore figure 4.2.1.1-21a can be used for parabolic-nose-cylinders and

figure 4.2.1.1-21b for 3/4-power-nose-cylinders with sufficient accuracy for most purposes.

The increments in normal-force-curve slope due to the addition of a boattailed or a flared body of revolution at the end of a semi-infinite cylindrical body are presented in figures 4.2.1.1-22a and 4.2.1.1-22b, respectively. Both of these increments are based on the cross-sectional area of the cylindrical body preceding the boattail or the flare. Figure 4.2.1.1-22a is taken from reference 10 and is based on the results of reference 8. Figure 4.2.1.1-22b is based on impact theory.

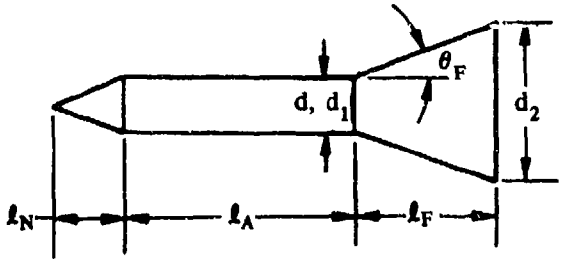
A comparison of test data with C_{N_α} of ogive-cylinder and cone-cylinder bodies calculated by this method is presented as table 4.2.i.1-B. The ranges of body geometry and Mach number of the test data are:

Cone-Cylinder					Ogive-Cylinder				
0	$\leq$	f_A	$\leq$	10.00	0	$\leq$	f_A	$\leq$	11.00
2.50	$\leq$	f_N	$\leq$	7.00	1.50	$\leq$	f_N	$\leq$	7.00
0	$\leq$	f_A/f_N	$\leq$	3.17	0	$\leq$	f_A/f_N	$\leq$	3.87
1.36	$\leq$	M	$\leq$	5.04	1.28	$\leq$	M	$\leq$	5.04

No method is available for estimating the lift-curve slope of a body of noncircular cross section. Consequently, test data must be relied upon as the basis for predicting the lift-curve slope of such configurations. A summary of available test data on bodies of noncircular cross section at supersonic speeds is presented as table 4.2.1.1-C.

Sample Problem

Given: The cone-cylinder-flare body of reference 27.



ℓ_N = 1.21 in. ℓ_A = 4.00 in. ℓ_F = 2.40 in.

d = d_1 = 1.0 in. d_2 = 2.75 in.

θ_F = 20°

M = 5.05; β = 4.95

Compute:

Cone-cylinder:

$f_N = \ell_N/d = 1.21$

$f_A = \ell_A/d = 4.00$

$f_A/f_N = 4.0/1.21 = 3.31$

$f_N/\beta = 1.21/4.95 = 0.244$

C_{N_α} = 3.52 per rad (linear extrapolation, figure 4.2.1.1-21b)
(based on cone-cylinder maximum frontal area)

Flare:

$d_2/d_1 = 2.75$

$\dfrac{(\Delta C_{N_\alpha})_F}{\cos^2 \theta_F} = 13.30$ (figure 4.2.1.1-22b)

$(\Delta C_{N_\alpha})_F = 13.30 \quad (\cos 20^o)^2$

$= 11.73$ per rad (based on $\dfrac{\pi d_1^2}{4}$ = cone-cylinder maximum frontal area)

Solution:

$C_{N_\alpha} = C_{N_\alpha}{}_{\text{cone-cylinder}} + (\Delta C_{N_\alpha})_F$

$= 3.52 + 11.73$

$= 15.25$ per rad (based on cone-cylinder maximum frontal area)

This compares with a test value of 17.70 per radian from reference 27.

D. HYPERSONIC

Newtonian impact theory is used for estimating the normal-force-curve slope of bodies of revolution at hypersonic Mach numbers. Newtonian theory assumes that the component of momentum normal to the surface is canceled on impact, thus giving rise to a normal force. The stagnation pressure predicted by Newtonian theory is about ten percent higher than the theoretical adiabatic pressure rise for an infinite Mach number. To correct this overestimation, a modified Newtonian method has been developed in which the assumptions of Newtonian flow are used, but the theoretical stagnation-pressure coefficient for the Mach number being considered is substituted for the Newtonian stagnation-pressure coefficient. Another modification of Newtonian theory considers the centrifugal forces in the flow around bodies of revolution (reference 14). This effect is small for conventional slender noses such as cones and ogives at moderate angles of attack, and the pressure forces on such slender noses are satisfactorily approximated by simple impact theory. For cylindrical afterbodies, inclusion of the effect of the centrifugal forces reduces the estimated normal-force-curve slope approximately ten percent.

Newtonian theory and its modifications are discussed in detail in reference 14. In this work Newtonian analysis is presented for an arbitrary body of revolution and the resulting forces on a cone and cylinder are given. In reference 15 a method of application of Newtonian concepts similar to that of reference 14 is presented. Reference 15 presents design charts which allow the aerodynamic characteristics of arbitrary

bodies of revolution to be obtained without the computation or radial integration of pressure distributions. In reference 16 the modified Newtonian approximation for the pressure distribution on bodies of revolution has been used to derive expressions for the aerodynamic characteristics at zero angle of attack for blunted cones, truncated cones, spherical segments, and rounded-shoulder cylinders. Approximate equations are also presented which may be used in conjunction with the design charts to obtain the zero angle-of-attack characteristics of composite missile components. The Datcom method uses the results of Newtonian impact theory presented in reference 17. This work presents design charts and equations for determining the aerodynamic characteristics of missile shapes composed of one or more cone frustums with or without a spherical nose. In addition, design charts are presented for the special cases of spherically blunted cones and ogives which can be used in conjunction with the results of reference 17.

DATCOM METHOD

The normal-force-curve slope of a body composed of one or more cone frustums with or without a spherical nose, a blunted conical nose, or a blunted ogival nose, based on the body base area, is given by

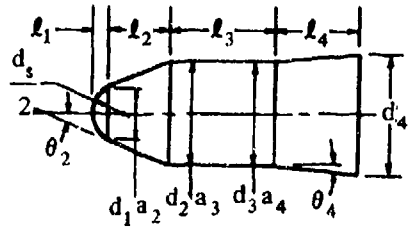
$$C_{N_\alpha} = \sum_{n=1}^{m} \left(C_{N_\alpha}\right)_n \left(\frac{d_n}{d_b}\right)^2 \qquad 4.2.1.1\text{-b}$$

To apply equation 4.2.1.1-b the body is divided into m segments, the first segment being either a spherical nose, a blunted conical nose, a blunted ogival nose, or a cone frustum, and each succeeding segment a cone frustum. The normal-force-curve slope of a spherical nose, based on its base area, is obtained from figure 4.2.1.1-23. The normal-force-curve slope of a blunted conical or blunted ogival nose, based on their respective base areas, is obtained from figures 4.2.1.1-24 and 4.2.1.1-25, respectively. The normal-force-curve slope of a cone frustum, based on the base area of the specific segment, is obtained from figure 4.2.1.1-26. (Note that a cylinder is considered a cone frustum with $\theta = 0$ and $a/d = 1.0$, and that $C_{N_\alpha} = 0$ by Newtonian impact theory.) The ratio $(d_n/d_b)^2$ refers the normal-force-curve slope to the base area of the configuration.

It should be noted that the design charts used in this method are based on Newtonian theory with no modifications of the stagnation-pressure coefficient or the centrifugal forces.

Sample Problem

Given: Configuration 5115 of reference 45, consisting of a cone-cylinder-frustum body with a spherical nose.



All dimensions in feet

Spherical Segment

$$\ell_1 = 0.18 \qquad \frac{d_s}{2} = 0.36 \qquad d_1 = 0.62$$

Forward Cone Frustum

$$a_2 = 0.62 \qquad d_2 = 1.20$$

$$\ell_2 = 0.72 \qquad \theta_2 = 22.5^\circ$$

Cylinder

$a_3 = 1.20$

$\ell_3 = 1.20$

$d_3 = 1.20$

$\theta = 0$

Rear Cone Frustum

$a_4 = 1.20$

$\ell_4 = 0.96$

$d_4 = d_b = 1.368$

$\theta_4 = 5^\circ$

Compute:

Spherical Segment

$2\ell_1/d_s = 0.18/0.36 = 0.50$

$\left(C_{N_\alpha}\right)_1 = 0.75$ per rad (figure 4.2.1.1-23) $\left(\text{based on } \frac{\pi d_1^2}{4}\right)$

Foreward Cone Frustum

$a_2/d_2 = 0.62/1.20 = 0.517$

$\left(C_{N_\alpha}\right)_2 = 1.250$ per rad (figure 4.2.1.1-26) $\left(\text{based on } \frac{\pi d_2^2}{4}\right)$

Cylinder

$a_3/d_3 = 1.20/1.20 = 1.00$

$\left(C_{N_\alpha}\right)_3 = 0$ (figure 4.2.1.1-26)

Rear Cone Frustum

$a_4/d_4 = 1.20/1.368 = 0.877$

$\left(C_{N_\alpha}\right)_4 = 0.450$ per rad (figure 4.2.1.1-26) $\left(\text{based on } \frac{\pi d_b^2}{4}\right)$

Solution:

$$C_{N_\alpha} = \sum_{n=1}^{m} \left(C_{N_\alpha}\right)_n \left(\frac{d_n}{d_b}\right)^2 \quad \text{(equation 4.2.1.1-b)}$$

$$= (C_{N_\alpha})_1 \left(\frac{d_1}{d_b}\right)^2 + (C_{N_\alpha})_2 \left(\frac{d_2}{d_b}\right)^2 + (C_{N_\alpha})_3 \left(\frac{d_3}{d_b}\right)^2 + (C_{N_\alpha})_4 \left(\frac{d_4}{d_b}\right)^2$$

$$= (0.75) \left(\frac{0.62}{1.368}\right)^2 + (1.250) \left(\frac{1.20}{1.368}\right)^2 + (0) \left(\frac{d_3}{d_b}\right)^2 + (0.450) \left(\frac{1.368}{1.368}\right)^2$$

$$= 0.1540 + 0.9618 + 0 + 0.450$$

$$= 1.566 \text{ per rad} \left(\text{based on configuration base area } \frac{\pi d_b^2}{4}\right)$$

This compares with a test value of 1.719 per radian from reference 45 at a Mach number of 4.04.

4.2.1.2 BODY LIFT IN THE NONLINEAR ANGLE-OF-ATTACK RANGE

Potential-flow theory shows that the lift on a body is a linear function of angle of attack and is proportional to the body base area. In particular, the lift on a closed body is zero. Slender-body theory also shows that the lift of an inclined body is independent of Mach number from low subsonic to supersonic Mach numbers.

The prediction of body-lift characteristics using potential-flow theory is necessarily limited to those cases where negligible viscous flow separation occurs, i.e., low angles of attack. Divergence between test data and potential-flow predictions can occur at very low angles of attack. Thus, to eliminate the potential-flow-theory angle-of-attack limitation requires consideration of the viscous flow separation effects.

Experimentally, the flow separates over the leeward side of the body, and the normal force increases nonlinearly with angle of attack. A pair of standing body vortices originate near the nose and increase in strength along the length of the body. A cross section of the flow is very similar to the two-dimensional flow about an infinite cylinder with laminar separation. That is, the flow separates in the region of the lateral meridians of the body rather than at points closer to the top meridian, as in turbulent separation. This effect is further accentuated by shocklets that appear (at subsonic speeds) near the maximum half-breadth at about $M \approx 0.4$ and fix the boundary-layer separation. For these reasons a cross-flow drag coefficient for laminar-boundary-layer conditions is used to evaluate viscous cross-flow forces for body lift even though the actual boundary layer is usually turbulent.

Several methods have been developed that assume that the normal forces acting on bodies of revolution at angles of attack can be represented by the linear combination of potential-flow and viscous cross-flow contributions. The lift-curve slope at zero angle of attack is used for the potential-flow term. Some form of cylinder cross-flow drag is used to evaluate viscous cross-flow lift. The methods differ mainly in their treatment of the nonlinear cross-flow term. Some of the better known methods for subsonic and supersonic analyses are discussed below.

In Reference 1 Allen and Perkins assume that the viscous contribution at each station along the body is equal to the steady-state drag of a section of an infinite cylinder placed normal to the flow with velocity $V \sin \alpha$. This method is accurate to within ±10 percent for high fineness-ratio bodies (fineness ratios of approximately 20 or greater). However, the accuracy of the method deteriorates as fineness ratio is decreased.

Kelly, in Reference 2, presents a method that is a refinement of that presented in Reference 1. Kelly uses the hybrid theory of Van Dyke (Reference 3), with a correction for boundary-layer displacement thickness for the potential-flow contribution. For the viscous term, the unsteady cross-flow drag of a cylinder started impulsively from rest is used instead of the steady-state value. This method is limited to cross-flow Mach numbers less than 0.4 and to values of the parameter $2f \tan \alpha \leqslant 9$.

The method of Reference 4 assumes that viscous cross-flow effects occur only on the cylindrical afterbody.

These methods are approximate, however, and each gives accurate answers over a limited range of test conditions. None of them is valid for all conditions.

A. SUBSONIC

Three methods are presented for predicting body lift. The first method, taken from Reference 5, applies only to bodies of revolution and is rather general in its application. It is based on the assumption that the flow is potential over the forward part of the body and has no viscous contribution in this region. On the aft part of the body, the flow is assumed to be entirely viscous, with lift arising solely from cross-flow drag.

The second method applies to bodies of elliptical cross section and bodies of revolution. This method is based on the concept of vortex lift for sharp delta wings as presented in Reference 6. The method as presented herein has been extended to include a set of empirical curves designed to estimate the angle of attack where the onset of vortex lift begins. This modification to the theory is necessary, since the onset of vortex lift for thick bodies does not correspond to that for flat-plate wings, i.e., zero angle of attack. The experimental data used in the correlation are presented in References 7 through 11.

The third method is, in principle, the most general in application, but can be substantiated the least by test data. This method, presented in Reference 12 by Jorgensen, applies to bodies of arbitrary cross section and angles of attack from 0 to 180^{o} in the Mach-number range from 0 to 7. The method is based on the original proposal of Allen (Reference 1), that the cross flow or lift distribution over a body can be expressed as the sum of a slender-body potential term and an empirical viscous cross-flow term. Although the method has been extended in the literature to include bodies with nonconstant cross sections of various types with and without lifting surfaces and afterbodies (References 12 and 13), the lack of substantiating test data has restricted the Datcom method to bodies with constant circular and elliptical cross sections. References are cited to assist in analyzing other configurations. Normal-force coefficient is calculated by this method. See Section 4.2.3.2 for calculation of axial-force coefficient using the method of Jorgensen. The experimental data used in the correlation are presented in References 12, 14, 15, and 16.

As noted above, all methods are applicable to bodies of revolution. It is suggested that Method 1 be used for bodies of revolution at low angles of attack because of its general application and sensitivity to the many possible body profile shapes. It should be noted that for those cases where the predictions from Method 1 diverge from test data (approximately 12^{o} angle of attack or higher), they generally tend to underpredict the lift coefficient. Conversely, the results from Method 2 generally tend to yield estimates that exceed the test data in the high-angle-of-attack range. Therefore, it is recommended that Method 3 be used in the high-angle-of-attack range.

DATCOM METHODS

Method 1

The expression for the lift coefficient of a body of revolution, based on $V_B^{2/3}$, taken from Reference 5, is

$$C_L = \frac{(k_2 - k_1)\, 2\alpha S_o}{V_B^{2/3}} + \frac{2\alpha^2}{V_B^{2/3}} \int_{x_o}^{x_B} \eta\, r\, c_{d_c}\, dx \qquad 4.2.1.2\text{-a}$$

where

$\frac{(k_2 - k_1)\, 2\alpha\, S_o}{V_B^{2/3}}$ is the potential-flow contribution from Paragraph A of Section 4.2.1.1.

α is the angle of attack in radians.

η is the ratio of the drag on a finite cylinder to the drag on an infinite cylinder, obtained from Figure 4.2.1.2-35a.

r is the body radius at any longitudinal station.

c_{d_c} is the steady-state cross-flow drag coefficient of a circular cylinder of infinite length, obtained from Figure 4.2.1.2-35b.

ℓ_B is the body length.

The remaining terms are defined in Paragraph A of Section 4.2.1.1.

The lift coefficients of several bodies of revolution, calculated by the Datcom method, have been compared with test data in Reference 5. In general, the accuracy of the method is satisfactory up to angles of attack of approximately 12^o.

Method 2

The expression for the lift coefficient of bodies of revolution and elliptical cross-section bodies, based on the projected body planform area, is given by

$$C_L = K_p \sin\alpha \cos^2\alpha + K_v \sin^2(\alpha - \alpha_v)\cos(\alpha - \alpha_v) \qquad 4.2.1.2\text{-b}$$

where

K_p is the potential-flow lift parameter, obtained from Figure 4.2.1.2-36a as a function of body aspect ratio.

K_v is the viscous-flow lift parameter, obtained from Figure 4.2.1.2-36b as a function of body aspect ratio.

α is the body angle of attack.

α_v is the angle of attack where the onset of vortex lift begins, obtained from Figure 4.2.1.2-37 as a function of body fineness ratio and thickness ratio.

When $\alpha_v > \alpha$ the viscous-lift contribution (second term) of Equation 4.2.1.2-b is not considered; i.e., it is zero. Thus the second term is considered only for those cases where $\alpha - \alpha_v$ yields a positive value.

The test data used to generate Figure 4.2.1.2-37 were limited to Mach numbers less than 0.6. Therefore it is advisable that Equation 4.2.1.2-b be applied to Mach numbers less than 0.6. For higher Mach numbers the user is referred to the parametric test data contained in References 8 through 11.

A comparison of test data with results calculated by this method is presented in Table 4.2.1.2-A. It should be noted that these test data and all other available test data were used in the development of the empirical curves, which estimate the angle of attack where the onset of vortex lift begins.

In general, the accuracy of the method was found to be satisfactory up to angles of attack of approximately 20°.

For those noncircular cross-section bodies that cannot be analyzed by this method, the user is referred to the summary of available test data on bodies of noncircular cross section at subsonic speeds presented in Table 4.2.1.1-A.

Method 3

The normal-force coefficient* for bodies with circular and elliptical cross sections, based on cross-sectional reference area S, is given by

$$C_N = \left(\frac{C_N}{C_{N_{cir}}}\right)_{SB} \left(\frac{S_b}{S} \sin 2\alpha' \cos\frac{\alpha'}{2}\right) + \left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} \left(\eta c_{d_c} \frac{S_p}{S} \sin^2 \alpha'\right) \qquad 4.2.1.2\text{-c}$$

where

$\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB}$ is the ratio of the normal-force coefficient for the body of noncircular cross section to that for the equivalent body of circular cross section (same cross-sectional area) as determined by slender-body theory. For circular cross sections this ratio is one. For elliptical cross sections this ratio is given by

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB} = \frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi \qquad 4.2.1.2\text{-d}$$

where

a is the major axis of the elliptical cross section.

b is the minor axis of the elliptical cross section.

ϕ is the angle of bank of the body about its longitudinal axis; $\phi = 0$ with the major axis horizontal, and $\phi = 90^{\circ}$ with the minor axis horizontal.

*The body lift can be determined by $C_L = C_N \cos\alpha + C_X \sin\alpha$ where C_X is obtained from Section 4.2.3.2.

S_b is the body base area.

S is the cross-sectional reference area of the cylindrical portion of the body (can be arbitrarily selected).

α' is an incidence angle defined as $\alpha' = \alpha$ for $0 \leqslant \alpha \leqslant 90^o$ and $\alpha' = 180^o - \alpha$ for $90^o \leqslant \alpha \leqslant 180^o$.

$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT}$ is the ratio of the normal-force coefficient for the body of noncircular cross section to that for the equivalent body of circular cross section (same cross-sectional area) as determined by Newtonian impact theory. For circular cross sections this ratio is one. For elliptical cross sections this ratio is described below.

When the major axis (a) is perpendicular to the cross-flow velocity,

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} = \frac{3}{2}\sqrt{\frac{a}{b}}\left\{\frac{-b^2/a^2}{\left(1-\frac{b^2}{a^2}\right)^{3/2}}\log_e\left[\frac{a}{b}\left(1+\sqrt{1-\frac{b^2}{a^2}}\right)\right]+\frac{1}{1-\frac{b^2}{a^2}}\right\}$$

4.2.1.2-e

When the minor axis (b) is perpendicular to the cross-flow velocity,

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} = \frac{3}{2}\sqrt{\frac{b}{a}}\left[\frac{a^2/b^2}{\left(\frac{a^2}{b^2}-1\right)^{3/2}}\tan^{-1}\left(\sqrt{\frac{a^2}{b^2}-1}\right)-\frac{1}{\frac{a^2}{b^2}-1}\right]$$

4.2.1.2-f

where a and b are as defined above.

η is the cross-flow drag proportionality factor, obtained from Figure 4.2.1.2-35a as a function of body fineness ratio.

c_{d_c} is the cross-flow drag coefficient of the cylindrical section, obtained from Figure 4.2.1.2-35b as a function of cross-flow Mach number M_c, where $M_c = M \sin \alpha$.

S_p is the body planform area. In applying the method to bodies with elliptical cross section, the term S_p in Equation 4.2.1.2-c is based on an equivalent body of revolution with the same cross-sectional area.

Reference 12 discusses methods of computing C_N for bodies with noncircular and nonelliptical cross sections. Reference 13 treats the general case of axially varying cross-sectional shape and bodies with lifting surfaces. However, since substantiating data for these methods are lacking, they have been omitted from the Datcom.

It is noted in Reference 12 that the cross-flow drag coefficient c_{d_c} may be reduced dramatically under the simultaneous conditions of $M_c \leq 0.4$ and $R_\ell \sin\alpha > 10^5$ (R_ℓ is Reynolds number based on diameter). These conditions have only recently been analyzed in detail and have not been included in the Datcom method because of considerable uncertainty in the magnitude and trend of the effects. For more detailed information regarding these effects, the user should refer to Reference 12.

Although the method is applicable up to $\alpha = 180^\circ$, no test verification has been obtained for $\alpha > 60^\circ$ at subsonic speeds. Table 4.2.1.2-B presents substantiation data taken at two Mach numbers. The calculated values for C_N tend to underestimate the test values at high α's. The method is probably less accurate as transonic speeds are approached ($M > 0.9$). It is further recommended that Methods 1 and 2 be used at the low angles of attack whenever possible, since the accuracies of these methods are better substantiated at low α's.

Sample Problems

Method 1

Given: An ogive-cylinder-boattail body of revolution of Reference 20. This is the body of the sample problem of Paragraph A of Section 4.2.1.1.

Body Characteristics:

$d = 5.0$ in. $\quad \ell_N = 26.25$ in. $\quad \ell_C = 23.77$ in. $\quad \ell_A = 13.45$ in.

$d_b = 3.30$ in. $\quad \ell_B = 63.47$ in. $\quad f = \ell_B/d = 12.7$

$(k_2 - k_1) = 0.960$

$V_B^{2/3} = 0.660$ sq ft

$x_o = 50.34$ in.

$S_o = 0.134$ sq ft

(Sample Problem, Paragraph A, Section 4.2.1.1)

Additional Characteristics:

$M = 0.80 \qquad \alpha = 4^\circ, 8^\circ, 12^\circ, 16^\circ, 20^\circ$

Compute:

$$\frac{(k_2 - k_1)\, 2\alpha\, S_o}{V_B^{2/3}} = \frac{(0.960)\,(2)\,\alpha\,(0.134)}{0.660} = 0.390\,\alpha$$

$c_{d_c} = f(M_c);\ M_c = M \sin \alpha$

M_c varies from $0.80 \sin 4^o$ to $0.80 \sin 20^o$; $0.056 \leqslant M_c \leqslant 0.274$

$c_{d_c} = 1.20$ (constant) (Figure 4.2.1.2-35b)

$\eta = 0.710$ (Figure 4.2.1.2-35a)

$$\int_{x_o}^{\ell_B} \eta\, r\, c_{d_c}\, dx = \int_{50.34}^{63.47} (0.710)\,(r)\,(1.20)\, dx$$

$$= (0.710) \left(\frac{2.48 + 1.65}{2}\right) (1.20)\,(63.47 - 50.34)$$

$$= 23.10 \text{ sq in.} = 0.160 \text{ sq ft}$$

Solution:

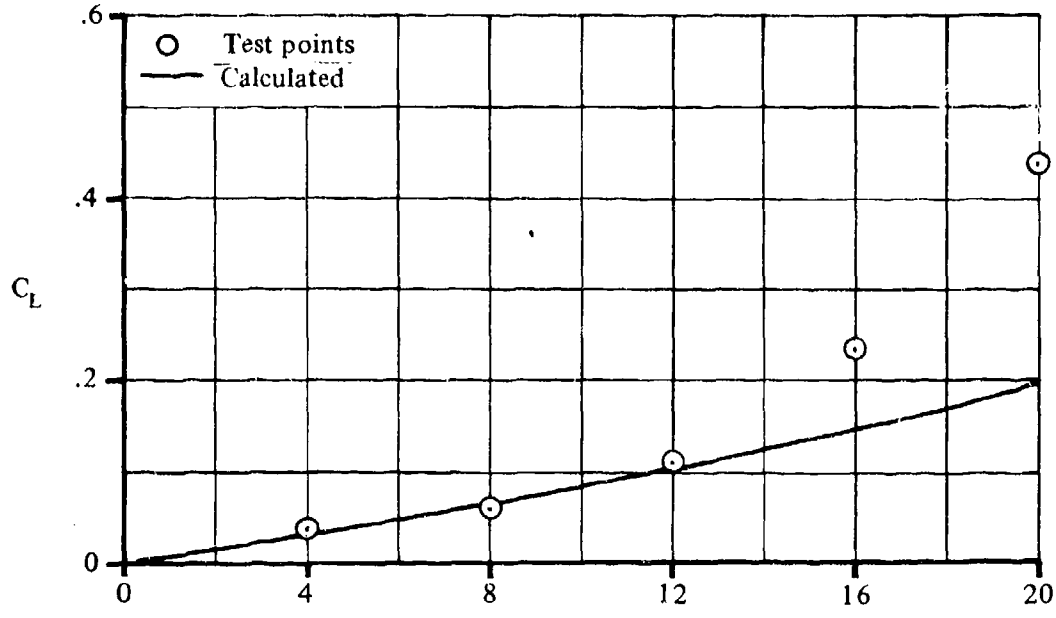
$$C_L = \frac{(k_2 - k_1)\, 2\alpha S_o}{V_B^{2/3}} + \frac{2\alpha^2}{V_B^{2/3}} \int_{x_o}^{\ell_B} \eta\, r c_{d_c}\, dx \qquad \text{(Equation 4.2.1.2-a)}$$

$$= 0.390\,\alpha + \frac{2\alpha^2}{0.660}\,(0.160)$$

$$= 0.390\,\alpha + 0.485\,\alpha^2$$

α (deg)	α (rad)	C_L (based on $V_B^{2/3}$) Eq. 4.2.1.2-a
4	0.0698	0.0296
8	0.1396	0.0639
12	0.2094	0.1030
16	0.2792	0.1467
20	0.3490	0.1954

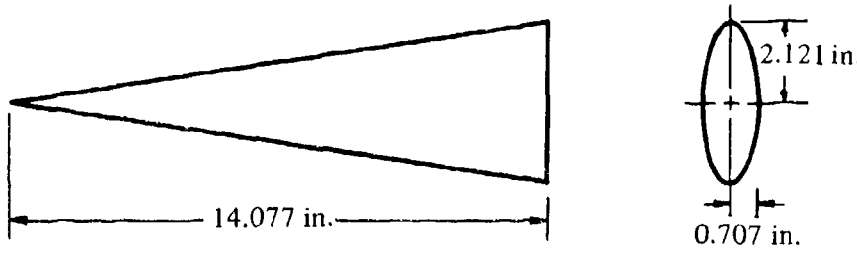
The calculated results are compared with test values in Sketch (a).



SKETCH (a)

Method 2

Given. The Model A elliptical cross-section body of Reference 11.



PLANFORM

$S = 29.857$ in.^{2} $A = 0.602$ $S_b = 4.712$ in.^{2}

$M = 0.60$ $R_\ell = 1.4 \times 10^6$

Compute:

$$d_{equiv} = 2\sqrt{\frac{ab}{4}}$$

$$= 2\sqrt{(0.707)(2.121)}$$

$$= 2.45$$

$$f = \frac{\ell_B}{d_{equiv}} = \frac{14.077}{2.45} = 5.74$$

$$\frac{a}{b} = \frac{2.121}{0.707} = 3.0$$

$K_p = 0.85$ (Figure 4.2.1.2-36a)

$K_v = 3.14$ (Figure 4.2.1.2-36b)

$\alpha_v = 4.3^o$ (Figure 4.2.1.2-37)

Solution:

$$C_L = K_p \sin\alpha \cos^2\alpha + K_v \sin^2(\alpha - \alpha_v)\cos(\alpha - \alpha_v)$$ (Equation 4.2.1.2-b)

①	②	③	④
α (deg)	$K_p \sin\alpha \cos^2\alpha$ (Potential component)	$K_v \sin^2(\alpha - \alpha_v)\cos(\alpha - \alpha_v)$ (Vortex component)	C_L ② + ③

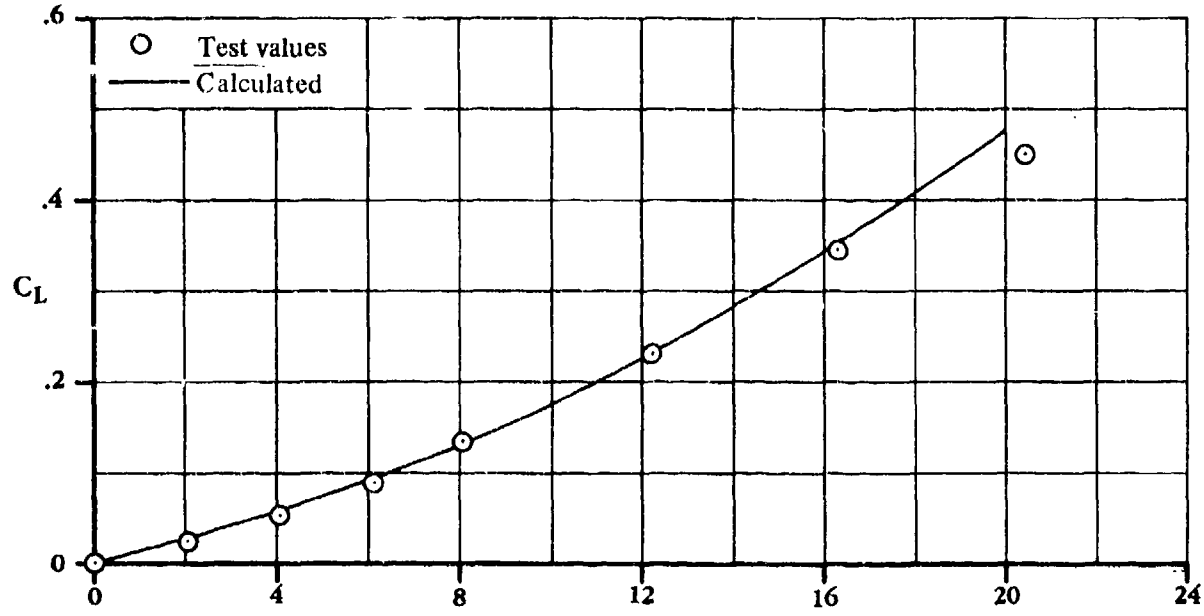
20	0.2567	0.2215	0.4782

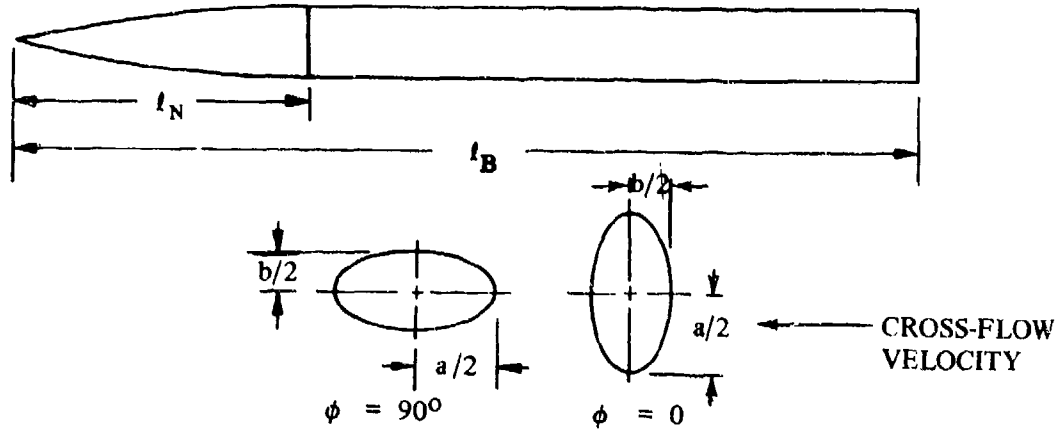
The calculated values are compared with test values from Reference 11 in Sketch (b).



SKETCH (b)

Method 3

Given: Elliptical cross-sectional body with tangent ogive nose of Reference 15.



Body Characteristics:

$\frac{a}{2}$ = 4.667 cm $\quad \ell_B$ = 66.0 cm $\quad S_p$ = 392.466 cm^2

$\frac{b}{2}$ = 2.333 cm $\quad \ell_N$ = 19.8 cm

Additional Characteristics:

$\alpha = 50^{o}$ $\phi = 0$ $M = 0.6$ $R_{\ell} = 6.5 \times 10^{5}$ (based on diameter)

and the major axis (a) is perpendicular to cross-flow velocity.

Compute:

$$\alpha' = \alpha = 50^{o}$$

$$S = \frac{\pi ab}{4} = \pi(4.667)(2.333) = 34.206 \text{ cm}^2$$

$$S_b = S = 34.206 \text{ cm}^2$$

$$d = d_{equiv} = 2\sqrt{\frac{ab}{4}} = 6.6 \text{ cm}$$

Slender-body potential-theory term

$$\frac{S_b}{S} \sin 2\alpha' \cos\frac{\alpha'}{2} = \frac{34.206}{34.206}(0.9848)(0.9063) = 0.8925$$

Viscous cross-flow term

$$f = \frac{\ell_B}{d} = \frac{66.0}{6.6} = 10$$

$\eta = 0.685$ (Figure 4.2.1.2-35a)

$$M_c = M \sin\alpha = 0.6\,(0.7660) = 0.46$$

$c_{d_c} = 1.32$ (Figure 4.2.1.2-35b)

$$\eta c_{d_c} \frac{S_p}{S} \sin^2\alpha = (0.685)(1.32)\ \frac{392.466}{34.206}(0.766)^2 = 6.09$$

Ratios for noncircular cross section

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB} = \frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi \qquad \text{(Equation 4.2.1.2-d)}$$

$$= \frac{4.667}{2.333}(1) + \frac{2.333}{4.667}(0)$$

$$= 2.0$$

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} = \frac{3}{2}\sqrt{\frac{a}{b}}\left\{\frac{b^2/a^2}{\left(1 - \frac{b^2}{a^2}\right)^{3/2}}\log_e\left[\frac{a}{b}\left(1 + \sqrt{1 - \frac{b^2}{a^2}}\right)\right] + \frac{1}{1 - \frac{b^2}{a^2}}\right\}$$

(Equation 4.2.1.2-e)

$$= \frac{3}{2}\sqrt{\frac{4.667}{2.333}}\left\{\frac{(2.333)^2/(4.667)^2}{\left(1 - \frac{2.333^2}{4.667^2}\right)^{3/2}}\log_e\left[\frac{4.667}{2.333}\left(1 + \sqrt{1 - \frac{2.333^2}{4.667^2}}\right)\right] + \frac{1}{1 - \frac{2.333^2}{4.667^2}}\right\}$$

$$= 2.121\left\{-0.3849 \log_e 3.732 + 1.333\right\}$$

$$= 2.121\left\{-0.3849 (1.3169) + 1.333\right\}$$

$$= 1.752$$

Solution:

$$C_N = \left(\frac{C_N}{C_{N_{cir}}}\right)_{SB}\left(\frac{S_b}{S}\sin 2\alpha' \cos\frac{\alpha'}{2}\right) + \left(\frac{C_N}{C_{N_{cir}}}\right)_{NT}\left(\eta c_{d_c}\frac{S_p}{S}\sin^2\alpha'\right) \quad \text{(Equation 4.2.1.2-c)}$$

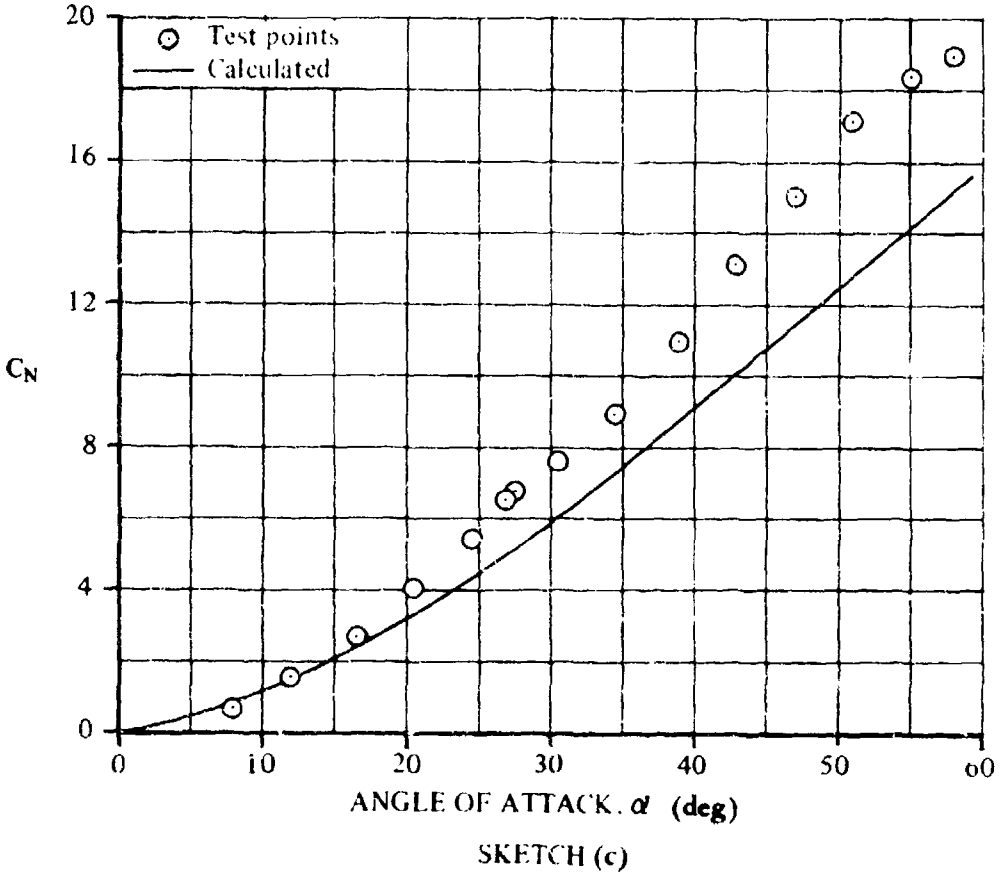
$$= 2.0\,(0.8925) + 1.752\,(6.09)$$

$$= 12.45 \text{ (based on body cross-sectional reference area, S)}$$

Additional values have been tabulated below:

M	α (deg)	C_N
0.6	10	1.2
0.6	20	3.2
0.6	30	5.9
0.6	40	9.0
0.6	50	12.5
0.6	60	16.8

The calculated results of the sample problem are compared to test values from Reference 15 in Sketch (c).



SKETCH (c)

B. TRANSONIC

At transonic Mach numbers, the flow about a body of moderate to large angles of attack is very complex. Analytically, the handling of inviscid mixed subsonic and supersonic flows, which interact at their mutual boundaries, is quite difficult. The presence of the body boundary layer, which may provide an additional mode of interaction between the locally subsonic and supersonic flows, presents an additional complication.

DATCOM METHOD

Because of the analytical difficulties of the problem, no method is given for estimating the transonic lift of a body at angle of attack. It is suggested that subsonic estimates be faired into supersonic results, with experimental data for similar configurations used as a guide in fairing. For bodies of revolution, the reader is referred to the test data of References 17 through 21.

For elliptical cross-section bodies in the transonic speed regime, the reader is referred to the parametric test data presented in References 8 through 11.

C. SUPERSONIC

Three methods are given for predicting body lift.The first method uses the results of the cross-flow analysis presented in Reference 1 to predict the lift on a body of revolution at angle of attack. This result has been modified by Jorgensen in Reference 22 to include bodies of elliptical cross section, and that modification is also presented under Method 1. The cross-flow method of Reference 1 is discussed at the beginning of this section.

The second approach uses hypersonic-similarity concepts that have been adapted to supersonic speeds. The hypersonic-similarity parameters are extended to supersonic Mach numbers by replacing M by β in the hypersonic parameters (Reference 23). Test data for a wide range of cone cylinders for Mach numbers between 1.57 and 4.24 are used in Reference 24 to derive supersonic design charts based on these modified hypersonic-similarity parameters. These charts are presented in this section. They have been slightly modified at the upper limit of their range to make them consistent with the hypersonic charts presented in Paragraph D. These charts can be used for pointed noses other than cones with only small losses in accuracy.

The third method is an improvement on Method 1 developed by Jorgensen in Reference 12. This method calculates the normal-force coefficient up to angles of attack of 180^{o} on bodies with circular and elliptic cross sections. The method is identical to that presented as Method 3 in Paragraph A of this section. It is recommended that this method b used at high angles of attack whenever the first two methods are not applicable

DATCOM METHODS

Method 1

The method presented for predicting the lift of a body of revolution at angle of attack is that of Allen and Perkins, in Reference 1. The lift of bodies of elliptical cross section is that of Reference 1 as modified by Jorgensen in Reference 22.

The lift coefficient of a body of revolution, based on body base area, is

$$C_L = 2\alpha + c_{d_c} \frac{S_p}{S_b} \alpha^2 \qquad 4.2.1.2\text{-g}$$

where

α is the angle of attack in radians.

c_{d_c} is the cross-flow drag coefficient, obtained from Figure 4.2.1.2-35b.

S_p is the body planform area.

S_b is the body base area.

The supersonic lift coefficient at angle of attack of a body having an elliptical cross section, based on body base area, is

$$\left(C_L\right)_{a/b} = \left[\frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi\right] C_L \qquad 4.2.1.2\text{-h}$$

where

- a is the major axis of the elliptical cross section.
- b is the minor axis of the elliptical cross section.
- ϕ is the angle of bank of the body about its longitudinal axis; $\phi = 0$ with the major axis horizontal and $\phi = 90^o$ with the minor axis horizontal.
- C_L is the lift coefficient of a body of revolution having the same cross-sectional area distribution along its axis as the elliptical-cross-section body of interest. It is given by Equation 4.2.1.2-g.

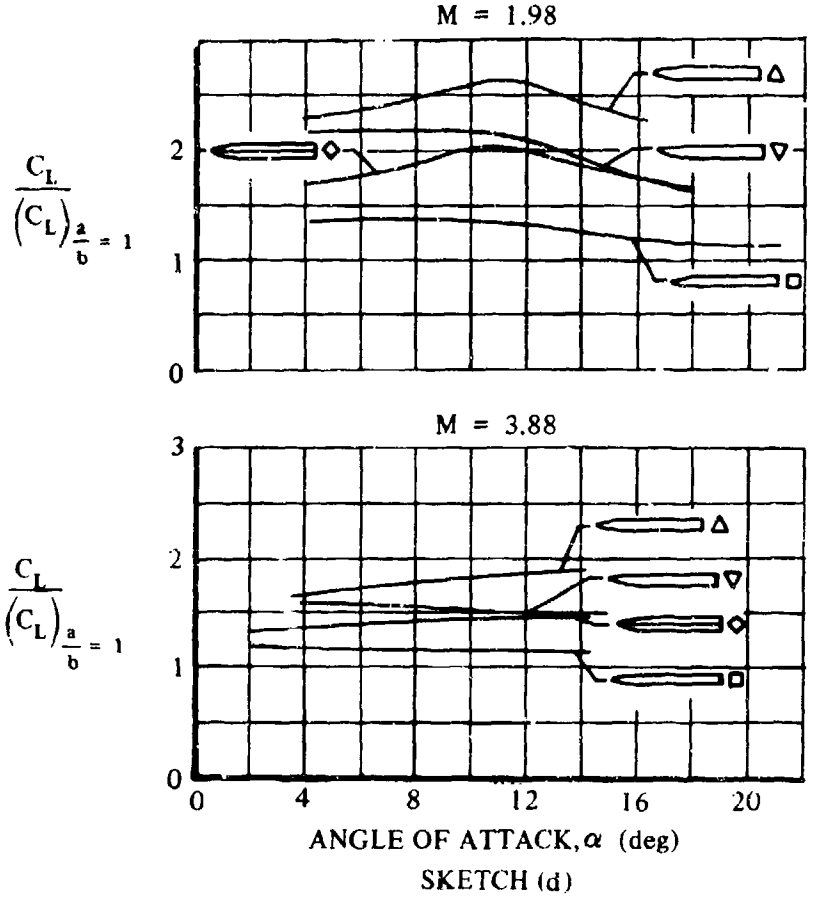
The Datcom method has been used to calculate the variation of lift coefficient with angle of attack for the bodies of elliptic cross section of Reference 22 and the bodies of revolution of References 1, 22, and 25 through 28. Although the nose shapes of most of the configurations analyzed were tangent ogives, a few bodies of revolution had conical or hemispherical noses. All the afterbodies were straight (no boattail or flare). In general, the calculated results agree well with test data, particularly for angles of attack up to approximately 10^o. The comparison of calculated and test values for the sample problems at the conclusion of Paragraph C of this section is indicative of the degree of accuracy of this method.

Method 2

The alternate method uses hypersonic-similarity parameters that have been adapted to supersonic speeds by the method of Reference 23. The variation of normal-force coefficient with angle of attack for pointed or nearly pointed bodies of revolution is estimated by using Figures 4.2.1.2-38a through -38d, where $\beta = \sqrt{M^2 - 1}$. The normal-force coefficient presented in these design charts is referred to the base area of the configurations.

With the exception of bodies with elliptical cross sections there are no methods for predicting the lift on bodies of noncircular cross section at supersonic speeds. A summary of available test data on bodies of noncircular cross section at supersonic speeds is presented as Table 4.2.1.1-C. It is of interest to note that in Reference 22 (Reference 37 of Table 4.2.1.1-C) the effect of cross-sectional shape on body aerodynamics has been assessed for bodies with circular, elliptic, square, and triangular cross sections. The results for bodies with noncircular cross sections have been compared with results for bodies of revolution having the same axial distribution of cross-sectional area. Data taken from Reference 22 are presented in Sketch (d), which shows the experimental ratio of the lift of bodies with square and triangular cross sections to the lift of the body of revolution having the same axial distribution of cross-sectional area as a function of angle of attack and Mach number.

These data show that at certain angles of bank, noncircular bodies develop considerably more lift than their equivalent bodies of revolution at a given angle of attack. The data of Reference 22 also show that the ratio of lift coefficient for a body of elliptic cross section to that for an equivalent body of revolution is practically constant with change in both angle of attack and Mach number, and that the ratio is given closely by slender-body theory. The slender-body-theory result for the ratio of potential-flow lift for an elliptic body to that for an equivalent body of revolution is the bracketed term in Equation 4.2.1.2-h, i.e., $\left[\frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi\right]$. No such simple correlation is available for other bodies of noncircular cross section.



SKETCH (d)

Method 3

The method of Jorgensen for bodies of revolution and bodies with elliptical cross sections, described in Method 3 of Paragraph A of this section, is also applicable throughout the supersonic speed regime up to M = 7. The method is applicable for angles of attack from 0 to 180°.

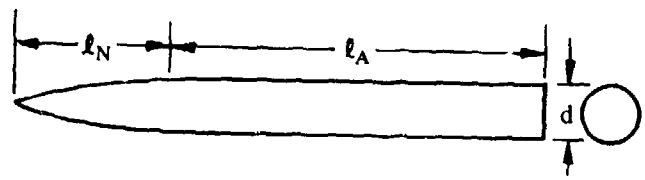
The cross-flow drag proportionality factor η in Equation 4.2.1.2-c is equal to 1.0 for $M \geq 1.0$.

Comparisons of calculated and test values of C_N are presented in Table 4.2.1.2-C for bodies with circular and elliptical cross sections and various nose shapes. The method is intended primarily for the high-angle-of-attack analysis, and it is recommended that either Datcom Method 1 or 2 be used at low angles of attack.

Sample Problems

1. Method 1

Given: An ogive-cylinder body of Reference 22



Body Characteristics:

$$f_N = \frac{\ell_N}{d} = 3.0 \qquad f_A = \frac{\ell_A}{d} = 7.0 \qquad f = \frac{\ell_B}{d} = 10.0$$

$d = 1.40$ in. $\qquad S_p = 17.66$ sq in. $\qquad S_b = 1.539$ sq in.

$$S_p/S_b = 11.47$$

Additional Characteristics:

$M = 1.98 \qquad \alpha = 4^o, 8^o, 12^o, 16^o, 20^o$

Compute:

$c_{d_c} = f(\alpha, M)$ (Figure 4.2.1.2-35b) (See calculation table below.)

Solution:

$$C_L = 2\alpha + c_{d_c} \frac{S_p}{S_b} \alpha^2 \qquad \text{(Equation 4.2.1.2-g) (based on } S_b\text{)}$$

① α (deg)	② α (rad)	③ α^2 (rad^2)	④ M_c $M \sin \alpha$	⑤ c_{d_c} Fig. 4.2.1.2-35b	⑥ 2α 2 (2)	⑦ $c_{d_c} \frac{S_p}{S_b} \alpha^2$ (5) (11.47) (3)	⑧ C_L Eq. 4.2.1.2-g (6) + (7)

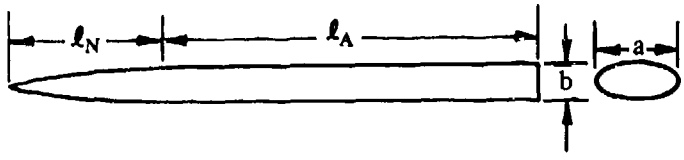
20	0.3490	0.12180	0.677	1.62	0.6980	2.2620	2.9600

2. Method 1

Given: A body of Reference 22 having an elliptical cross section and the same axial distribution of cross-sectional area as the body of revolution of Sample Problem 1.



Body Characteristics:

$a = 1.98$ in. $\quad b = 0.99$ in. $\quad a/b = 2.0 \quad \phi = 0$

Additional Characteristics:

$M = 1.98 \quad \alpha = 4^o, 8^o, 12^o, 16^o, 20^o$

Compute:

C_L vs α for a body of revolution having the same cross-sectional area distribution. (from Sample Problem 1)

Solution:

$$(C_L)_{a/b} = \left[\frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi\right] C_L \qquad \text{(Equation 4.2.1.2-h) (based on } S_b\text{)}$$

$$= [(2.0)(1.0) + 0]\, C_L = 2.0\, C_L$$

α (deg)	C_L Sample Problem 1	$(C_L)_{a/b}$ Eq. 4.2.1.2-h

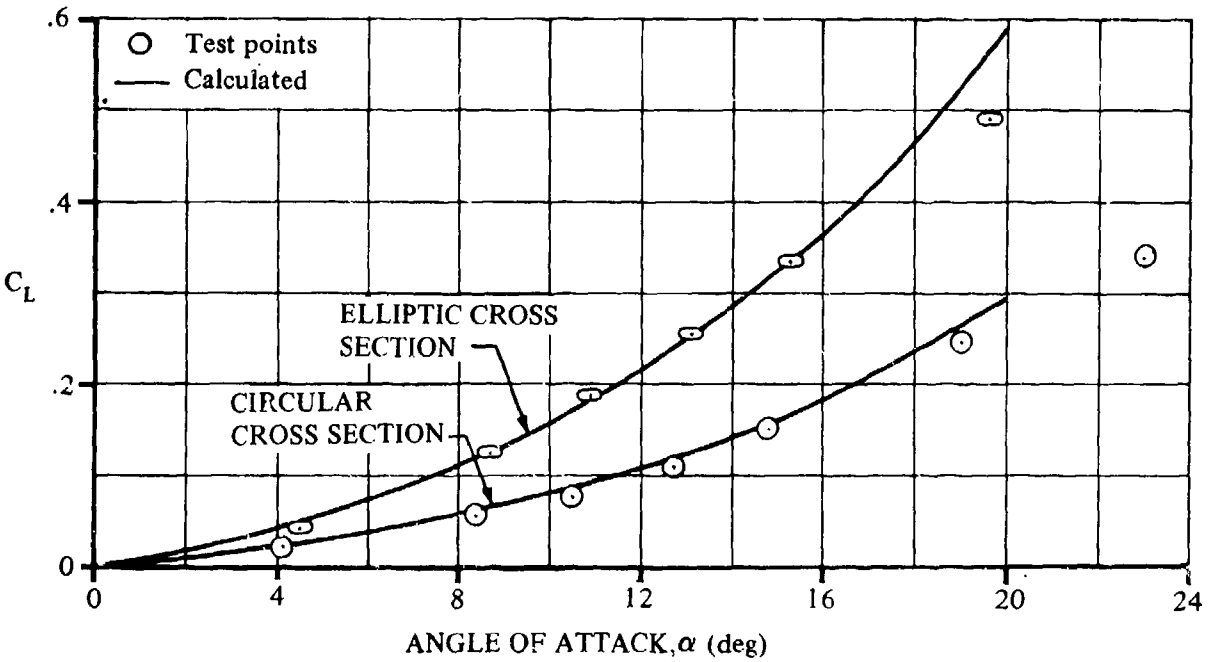
8	0.549	1.098
12	1.060	2.120
16	1.818	3.636
20	2.960	5.920

The calculated results of Sample Problems 1 and 2 are compared with test values from Reference 22 in Sketch (e).



SKETCH (e)

3. Method 3

Refer to Sample Problem 3 in Paragraph A of this section for an example of the application of the method.

D. HYPERSONIC

Three methods are presented for estimating forces on bodies of revolution at hypersonic speeds. One is the hypersonic-similarity method. Another is the Newtonian impact theory and its modifications, discussed in Paragraph D of Section 4.2.1.1. A third method is the method of Jorgensen presented in Paragraphs A and C of this section.

The first method presented in this section is based on hypersonic similarity with Newtonian-theory modifications. Data from References 23 and 29 through 32 have been correlated by means of the hypersonic-similarity parameters and the results extended to high Mach numbers by means of Newtonian theory. These data are limited to pointed, unflared bodies.

The incremental normal-force coefficient due to spherical nose blunting of cones has been calculated by using Newtonian theory. The calculations assume that pressures aft of the intersection of the sphere and the cone are not affected by the blunt nose.

Increments in normal forces due to the addition of flares on cylindrical bodies have also been calculated on the basis of Newtonian flow. Caution should be used in using body flares, however, because they can cause flow separation due to the pressure rise across the shock wave at the beginning of the flare. These separated flows can be unsteady and can cause large losses in lift and moment effectiveness. The conditions that aggravate boundary-layer separation tendencies are large flare angles, lower Mach numbers, high Reynolds number (for a given laminar or turbulent condition), and high wall temperatures. Corner radii or filleting can greatly alleviate this problem. Reference 33 gives some idea of the magnitude of these effects.

The second method is based on Newtonian impact theory. Design charts, taken from Reference 34, are presented for estimating the normal-force characteristics of arbitrary bodies of revolution. These charts are applicable to angles of attack up to 90^{O}.

The third method is the method given by Jorgensen in Reference 12, and presented as Method 3 of Paragraphs A and C of this section. This method calculates the normal-force coefficient up to angles of attack of 180^{O} on bodies with circular and elliptical cross sections. It is recommended that this method be used at high angles of attack whenever the first two methods are not applicable.

DATCOM METHODS

Method 1

The normal-force coefficient for a body composed of a circular cone-cylinder with or without a blunted nose and/or a flared skirt, based on the body base area, is

$$C_N = \left(C_N\right)_{\substack{\text{cone-}\\\text{cylinder}}} \left(\frac{d_{cyl}}{d_b}\right)^2 + \left(\Delta C_N\right)_N \left(\frac{d}{d_b}\right)^2 + \left(\Delta C_N\right)_F \qquad 4.2.1.2\text{-i}$$

where

$\left(C_N\right)_{\substack{\text{cone}\\\text{cylinder}}}$ is the normal-force coefficient of a circular cone-cylinder, based on the cylinder base area. This parameter is obtained from Figure 4.2.1.2-40.

$\left(\Delta C_N\right)_N$ is the increment in normal-force coefficient due to blunting the nose of the cone, based on the base area of the spherical nose segment. This parameter is obtained from Figure 4.2.1.2-42a.

$\left(\Delta C_N\right)_F$ is the increment in normal-force coefficient due to the addition of a flared body of revolution at the end of a semi-infinite cylindrical body, based on the base area of the flared body. This parameter is obtained from Figure 4.2.1.2-42b.

d_{cyl} is the diameter of the cylinder.

d is the diameter of the spherical nose segment. (See Figure 4.2.1.2-42a.)

d_b is the body base diameter.

Method 2

The expression for the normal-force coefficient of an arbitrary body of revolution, based on the body base area, taken from Reference 34, is

$$C_N = \frac{K}{\pi} \frac{\ell_B}{R} \int_0^1 K_\theta \frac{r}{R} d\left(\frac{x}{\ell_B}\right) \qquad 4.2.1.2\text{-j}$$

where

K = 2, according to Newtonian theory, which corresponds to $M_\infty = \infty$ and $\gamma = 1.0$. This value does not account for either Mach number or γ variations, but for pointed bodies with attached shocks it gives results of acceptable accuracy. For blunt bodies the actual value of the stagnation-point pressure coefficient may be used for K:

$$K = C_{P_{stag}} = \frac{\gamma + 3}{\gamma + 1}\left[1 - \frac{2}{\gamma + 3}\,\frac{1}{M_\infty^2}\right] \qquad 4.2.1.2\text{-k}$$

ℓ_B is the body length.

R is the reference radius (radius of the base).

r is the local radius at any body station.

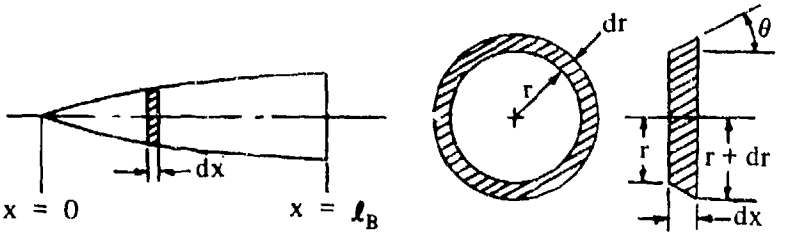
K_θ is a pressure-surface-slope integral factor obtained from Figure 4.2.1.2-43 as a function of angle of attack and the surface slope θ of the body of revolution.

The following steps outline the calculation procedure:

Step 1. From the equation of the body of revolution obtain the expression for the surface slope using the relation

$$\theta = \tan^{-1}\left(\frac{dr}{dx}\right)$$

where θ, dr, and dx are illustrated in Sketch (f).



ELEMENT OF SURFACE DETAIL

SKETCH (f)

Step 2. Compute the values of r/R and θ at various longitudinal stations x/ℓ_B.

Step 3. For various x/ℓ_B enter Figure 4.2.1.2-43 with the corresponding θ from Step 2 and obtain K_θ at the desired angle of attack.

Step 4. Plot the product $K_\theta \frac{r}{R}$ versus x/ℓ_B.

Step 5. Obtain C_N by integrating the area under the curve described in Step 4 and multiplying that value by $\frac{K}{\pi} \frac{\ell_B}{R}$.

Method 3

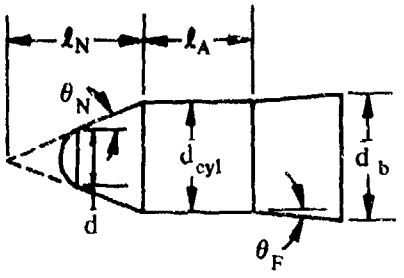
This method is identical to Method 3 presented in Paragraphs A and C of this section. The method is applicable to angles of attack from 0 to 180^o and Mach numbers up to 7. The method has been partially substantiated by test data from Reference 16 in Table 4.2.1.2-C.

The method shows reasonable agreement with test data at hypersonic speeds in the low-angle-of-attack range. Because of the scarcity of substantiating test data, caution should be used when applying the method at higher angles of attack ($\alpha > 25^o$).

Sample Problems

1. Method 1

Given: Configuration 5115 of Reference 35, consisting of a cone-cylinder-frustum body with a spherical nose. This is the configuration of the sample problem in Paragraph D of Section 4.2.1.1.



ℓ_N = 1.45 ft ℓ_A = 1.20 ft d = 0.62 ft d_{cyl} = 1.20 ft d_b = 1.268 ft

θ_N = 22.5^o θ_F = 5^o M = 4.04; β = 3.91

Compute:

$$f_A = \frac{\ell_A}{d_{cyl}} = \frac{1.20}{1.20} = 1.00$$

$$f_N = \frac{\ell_N}{d_{cyl}} = \frac{1.45}{1.20} = 1.21$$

$$f_A/f_N = 1.00/1.21 = 0.83$$

$$\beta/f_N = 3.91/1.21 = 3.23$$

$$(d/d_b)^2 = (0.62/1.368)^2 = 0.205$$

$$(d_{cyl}/d_b)^2 = (1.20/1.368)^2 = 0.769$$

$$1 - (d_{cyl}/d_b)^2 = 0.231$$

Solution:

$$C_N = \left(C_N\right)_{\substack{\text{cone-}\\\text{cylinder}}} \left(\frac{d_{cyl}}{d_b}\right)^2 + \left(\Delta C_N\right)_N \left(\frac{d}{d_b}\right)^2 + \left(\Delta C_N\right)_F \qquad \text{(Equation 4.2.1.2-i)}$$

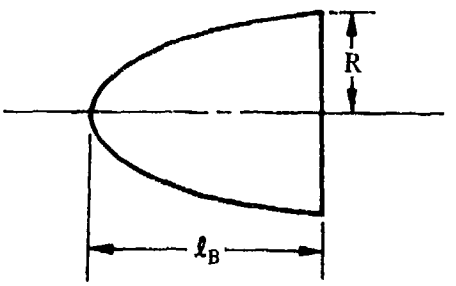
40	156.4	7.8	1.534	–1.350	–0.277	2.55	0.589	1.846

2. Method 2

Given: A second-power body of revolution of fineness ratio 1.0.



$x = \left(\frac{4}{\ell_B}\right) r^2$ (equation of body) $\quad \ell_B = 2.0$ ft $\quad R = 1.0$ ft

$M_\infty = 3.55 \quad \alpha = 6^o \quad \gamma = 1.40$

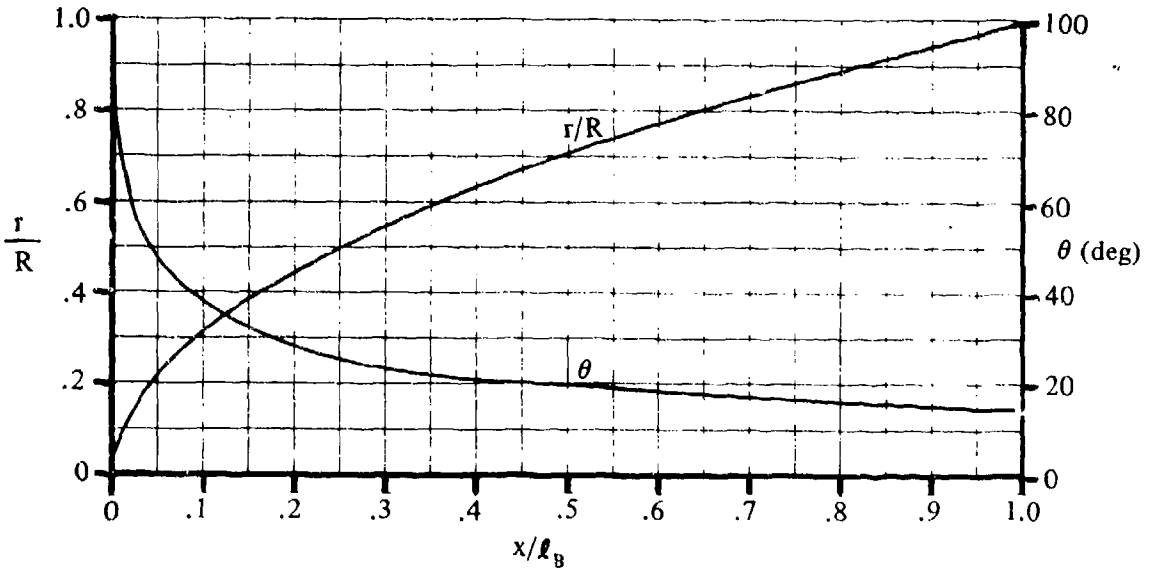
Compute:

Determine K for a blunt-nosed body

$$K = \frac{\gamma + 3}{\gamma + 1}\left[1 - \frac{2}{\gamma + 3}\,\frac{1}{M_\infty^2}\right] = 1.77 \qquad \text{(Equation 4.2.1.2-k)}$$

$$\theta = \tan^{-1}\left(\frac{dr}{dx}\right) = \tan^{-1}\left(\frac{1}{4\sqrt{x/\ell_B}}\right)$$

Calculate r/R and θ at various longitudinal stations x/ℓ_B and plot (see Sketch (g)).

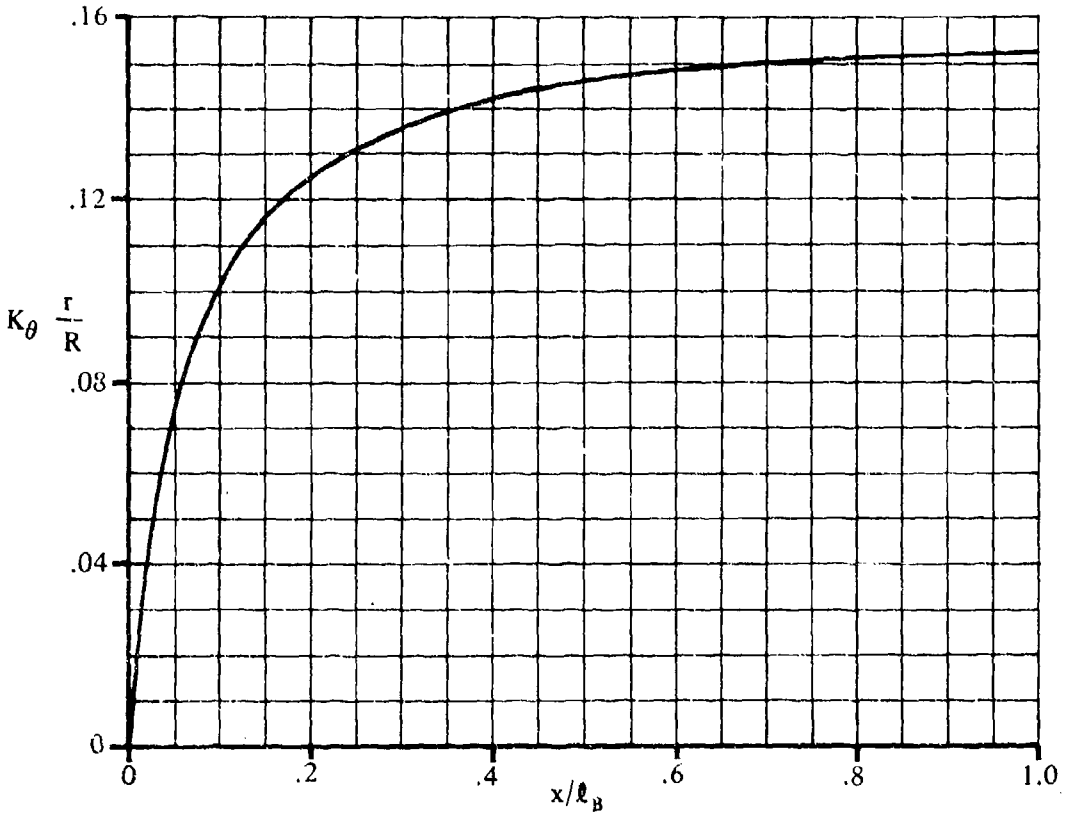


SKETCH (g)

Obtain values for K_θ from Figure 4.2.1.2-43 for various values of θ at $\alpha = 6^o$.

Plot the product of $K_\theta \frac{r}{R}$ versus x/ℓ_B (see Sketch (h)).

Integrate the area under the curve of Sketch (h). $\int_0^1 K_\theta \frac{r}{R} d\left(\frac{x}{\ell_B}\right) = 0.135$



SKETCH (h)

Solution:

$$C_N = \frac{K}{\pi} \frac{\ell_B}{R} \int_0^1 K_\theta \frac{r}{R} d\left(\frac{x}{\ell_B}\right) \quad \text{(Equation 4.2.1.2-j)}$$

$$= \frac{(1.77)(2.0)}{\pi \quad (1.0)}(0.135)$$

$$= 0.152 \text{ (based on } S_b)$$

3. Method 3

Refer to Sample Problem 3 in Paragraph A of this section for an example of the application of the method.

4.2.2 BODY PITCHING MOMENT

4.2.2.1 BODY PITCHING-MOMENT-CURVE SLOPE

A. SUBSONIC

Two methods are presented in this section for estimating the body pitching-moment-curve slope at angles of attack near zero. Several additional methods are presented in References 1 through 4 of Section 4.2.1.1. As in the case with lift, moments acting on bodies are frequently considered in the literature to be divisible into two contributions – one due to potential flow over the forward part of the body and the other due to viscous cross flow over the aft part of the body. The general discussion of Section 4.2.1.2 on these flow conditions is directly applicable to this section.

DATCOM METHODS

The two methods presented for calculating the body pitching-moment-curve slope are distinguished from one another in that Method 1 is applicable only to bodies in the presence of a wing flow field; whereas Method 2 is valid only when applied to a body in undisturbed flow.

It is not feasible to present generalized design charts; however, both Equations 4.2.2.1-a and -b can be integrated for any arbitrary body of revolution.

Method 1

Multhopp's method, taken from Reference 1, estimates the body pitching-moment-curve slope in the presence of a wing flow field. This method is valid for bodies of revolution in the low subsonic speed regime. Application of this method is practical only when test data are available for the wing pitching-moment-curve slope of the wing-body combination. This method then allows a separate analysis of the body effects to be made, enabling a build-up of the wing-body pitching-moment-curve slope based on test data for the wing contribution and on this method for the body contribution. If no wing pitching-moment-curve-slope test data are available, the method of Section 4.3.2.2 is recommended for estimating the wing-body pitching-moment-curve slope. The body pitching-moment-curve slope in the presence of a wing flow field, based on the product of wing area and wing MAC $S_W \bar{c}_W$, is given by

$$C_{m_\alpha} = \frac{1}{36.5\, S_W \bar{c}_W} \int_0^{\ell_B} w_f^2 \left(\frac{\partial \epsilon_u}{\partial \alpha} + 1 \right) dx \quad \text{(per degree)} \qquad 4.2.2.1\text{-a}$$

where

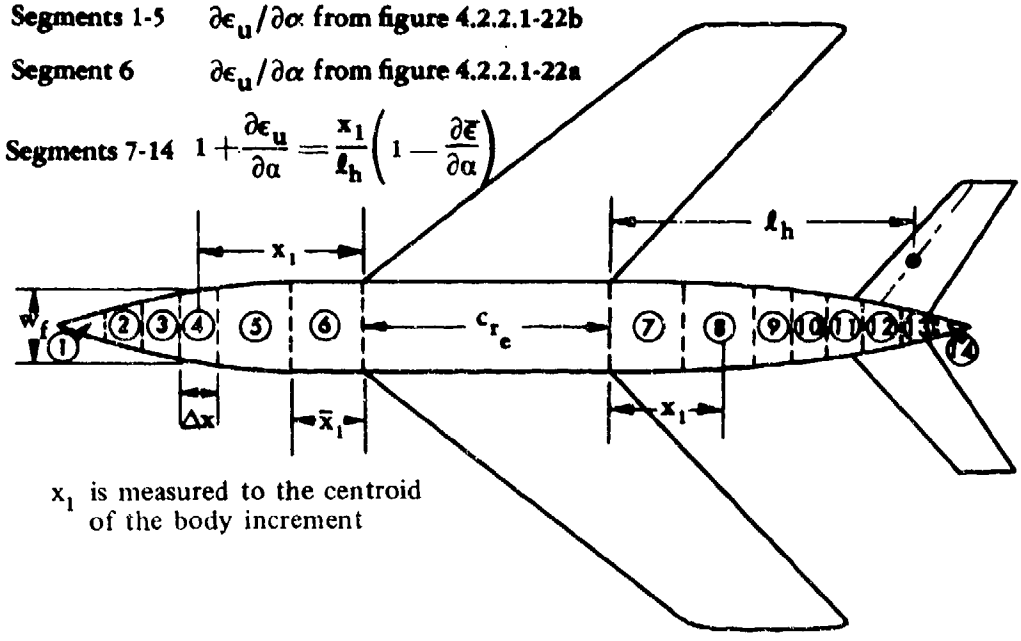
S_W is the wing reference area.

$\bar{c}_W$ is the wing mean aerodynamic chord.

ℓ_B is the length of the body.

w_f is the average width of a given body segment (see Sketch (a)).

$\frac{\partial \epsilon_u}{\partial \alpha}$ is the rate of change of upwash with respect to angle of attack. The estimation of $\frac{\partial \epsilon_u}{\partial \alpha}$ varies for various fuselage segments. These definitions of $\frac{\partial \epsilon_u}{\partial \alpha}$ with their respective body segments are presented in Sketch (a). The values of $\frac{\partial \epsilon_u}{\partial \alpha}$ for the body increments forward of the wing are estimated by the curves presented in Figures 4.2.2.1-22a and -22b. The separate curve for the body increment immediately forward of the wing is necessary because of the rapid increase of upwash in this vicinity. Both curves of $\frac{\partial \epsilon_u}{\partial \alpha}$ presented in Figures 4.2.2.1-22a and -22b are based on a wing-body lift-curve slope of 0.0785 per degree. To correct for other values of $\left(C_{L_\alpha}\right)_{WB}$, multiply the values of $\frac{\partial \epsilon_u}{\partial \alpha}$ obtained from these figures by the ratio $\left(C_{L_\alpha}\right)_{WB}/0.0785$. (The values of $\left(C_{L_\alpha}\right)_{WB}$ should be obtained from test data or Section 4.3.1.2 and expressed in units of per degree.) The estimation of $\frac{\partial \epsilon_u}{\partial \alpha}$ for that portion of the body aft of the wing is based on the assumption of a linear variation of downwash from the trailing edge of the exposed wing root chord to the horizontal tail. If the methods of Section 4.4.1 are to be used for estimating $\frac{\partial \bar{\epsilon}}{\partial \alpha}$, the downwash should be calculated for the trailing-edge point of the body; i.e., assume the horizontal-tail MAC quarter-chord point coincides with the trailing edge of the fuselage.



x_1 is measured to the centroid of the body increment

SKETCH (a)

Method 2

The method of Reference 2 is presented for estimating the body pitching-moment-curve slope. Only the potential-flow portion of the method of Reference 2 is applied, limiting the application of the method to angles of attack near zero. The body pitching-moment-curve slope, based on the total body volume V_B, is given by

$$C_{m_\alpha} = \frac{2(k_2 - k_1)}{V_B} \int_0^{x_o} \frac{dS_x}{dx}(x_m - x)\, dx \quad \text{(per radian)} \qquad 4.2.2.1\text{-b}$$

where

$(k_2 - k_1)$ is the apparent mass factor developed by Munk and given in Figure 4.2.1.1-20a.

V_B is the volume of the body.

x_o is the body station where the flow ceases to be potential. It is a function of x_1, the body station where the parameter dS_x/dx first reaches its maximum negative value. The parameters x_o and x_1 are correlated in Figure 4.2.1.1-20b.

S_x is the body cross-sectional area at any body station.

x_m is the longitudinal distance from the nose to the chosen moment center.

x is the location of the center of pressure of a given body segment, measured from the nose.

In many cases it will be possible to determine the location of x_1 by inspection. For cases that are doubtful, the area distribution should be plotted and examined to determine the location where dS_x/dx first reaches its maximum negative value.

The pitching-moment-curve slopes of several bodies of revolution have been calculated by this method and compared with test data in Reference 2. In general, the method has a fair degree of accuracy at angles of attack near zero.

For a rapid but approximate estimation, slender-body theory can be used, which gives

$$C_{m_\alpha} = 2\left(\frac{x_m}{\ell_B} + \frac{V_B}{S_b \ell_B} - 1\right) \quad \text{(per radian)} \qquad 4.2.2.1\text{-c}$$

where C_{m_α} is based on $S_b \ell_B$, S_b being the base area of the body of revolution and ℓ_B the total length of the body of revolution.

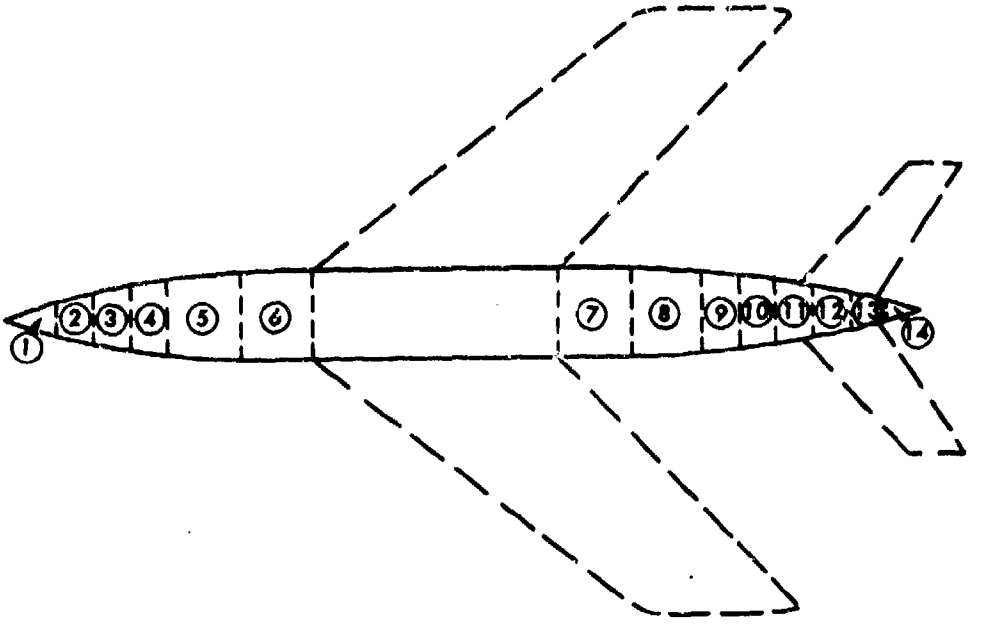
No method is available for estimating the pitching-moment-curve slope of a body of noncircular

cross section. Consequently, test data must be relied upon as the basis for predicting the pitching-moment-curve slope of such configurations. A summary of available test data on bodies of noncircular cross section at subsonic speeds is presented as Table 4.2.1.1-A.

Sample Problems

1. Body in the wing flow field

Given: The wing-body configuration of Reference 3



Body Increment	Δx (in.)	w_f (in.)	x_1 (in.)

$$\sum_{x=0}^{\ell_B} w_f^2 \left(\frac{\partial \epsilon_u}{\partial \alpha} + 1\right) \Delta x = 18{,}106.78 \text{ cu. in.}$$

Solution:

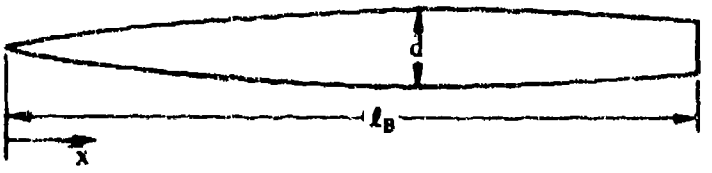
$$C_{m_\alpha} = \frac{1}{36.5\, S_w \bar{c}_w} \int_0^{\ell_B} w_f^2 \left(\frac{\partial \epsilon_u}{\partial \alpha} + 1\right) dx \quad \text{(Equation 4.2.2.1-a)}$$

$$= \frac{18{,}106.78}{(36.5)(4429)(39.97)} = 0.00280 \text{ per degree}$$

No test data are available for the body in the presence of the wing flow field.

2. Potential Flow

Given: The 3/4-power body of revolution of Reference 12.



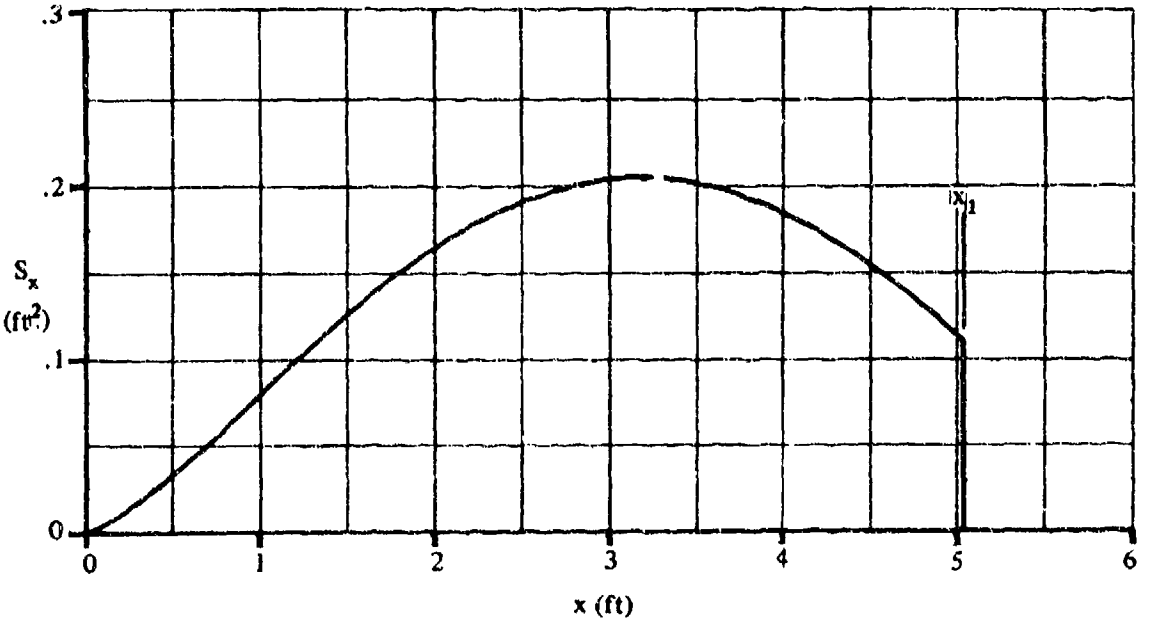
$$r = 0.255\left[1 - \left(1 - \frac{2x}{6.375}\right)^2\right]^{3/4} \qquad \ell_B = 5.036 \text{ ft} \qquad d = 0.510 \text{ ft}$$

$V_B = 0.687$ cu ft $\qquad f = \ell_B/d = 9.87 \qquad x_m = 3.54$ ft $\qquad M = 0.40$

Compute:

Determine x_1

The body station where dS_x/dx first reaches a maximum negative value can be determined by inspection; however, the area distribution is plotted to illustrate the determination of x_1.



Cross-Sectional Area Distribution

$x_1 = 5.036$ ft

$x_1/\ell_B = 5.036/5.036 = 1.0$

$x_o/\ell_B = 0.905$ (figure 4.2.1.1-20)

$x_o = (0.905)(5.036) = 4.558$ ft

$(k_2 - k_1) = 0.937$ (figure 4.2.1.1-20a)

$$\frac{2(k_2 - k_1)}{V_B} = \frac{2(0.937)}{0.687} = 2.728$$

Evaluate $\int_0^{x_o} \frac{dS_x}{dx} (x_m - x)\, dx$

$$\sum_{x=0}^{x_o} \frac{dS_x}{dx} (x_m - x)\Delta x = 0.474 \text{ cu ft}$$

Solution:

$$C_{m_\alpha} = \frac{2(k_2 - k_1)}{V_B} \int_0^{x_o} \frac{dS_x}{dx} (x_m - x)\, dx \quad \text{(equation 4.2.2.1-b)}$$

$$= (2.728)(0.474)$$

$$= 1.293 \text{ per rad (based on } V_B)$$

This compares with a test value of 1.369 per radian from reference 12.

*x is taken at the center of volume of each body segment.

3. Slender-Body Theory

Given: The same configuration as sample problem 2.

$x_m = 3.54$ ft $\quad \ell_B = 5.036$ ft $\quad V_B = 0.687$ cu ft $\quad S_b = 0.1103$ sq ft

Compute:

$$x_m/\ell_B = 3.54/5.036 = 0.7029$$

$$\frac{V_B}{S_b \ell_B} = \frac{0.687}{(0.1103)(5.036)} = 1.237$$

Solution:

$$C_{m_\alpha} = 2\left(\frac{x_m}{\ell_B} + \frac{V_B}{S_b \ell_B} - 1\right) \qquad \text{(equation 4.2.2.1-c)}$$

$$= 2(0.7029 + 1.237 - 1)$$

$$= 1.880 \text{ per rad (based on } S_b \ell_B)$$

$$= 1.52 \text{ per rad (based on } V_B)$$

B. TRANSONIC

Slender-body theory states that body force and moment characteristics are not functions of Mach number. Experimental data verify this result (references 4, 5, and 6). Any differences in the subsonic value of C_{m_α} obtained from paragraph A and the supersonic value of C_{m_α} obtained from paragraph C should be faired out smoothly in the transonic range. Experimental data should be used, when available, as a guide in fairing in the transonic range.

Transonic test data on bodies of noncircular cross section are available in references 25, 26, and 5 of table 4.2.1.1-A.

C. SUPERSONIC

Several theoretical methods have been developed that can be used for estimating the moment characteristics of bodies of revolution at supersonic speeds. However, these are best applied by machine methods. Some of these methods are discussed in paragraph C of Section 4.2.1.1.

DATCOM METHOD

An empirical method is presented, based on the data from reference 7, for ogive-cylinder and cone-cylinder bodies at supersonic speeds. Figure 4.2.2.1-23a gives the center-of-pressure location for ogive-cylinders, and figure 4.2.2.1-23b gives the center-of-pressure location for cone-cylinders. The moment slope, based on the product of the maximum frontal area and body length $S_B \ell_B$, is

$$C_{m_\alpha} = \left(\frac{x_m}{\ell_B} - \frac{x_{c.p.}}{\ell_B}\right) C_{N_\alpha} \quad \text{(per radian)} \qquad 4.2.2.1\text{-d}$$

where

$\frac{x_m}{\ell_B}$ is the desired moment-center location in fraction of body length.

$\frac{x_{c.p}}{\ell_B}$ is the center-of-pressure location in fraction of body length, obtained from figure 4.2.2.1-23a or figure 4.2.2.1-23b, depending upon the given configuration.

C_{N_α} is the normal-force-curve slope, based on maximum frontal area of the ogive-cylinder or cone-cylinder body, obtained from paragraph C of Section 4.2.1.1 (figures 4.2.1.1-21a and 4.2.1.1-21b, respectively).

Experimental data from reference 6 indicate that the center-of-pressure location of 1/2-power bodies is closely approximated by corresponding (same fineness ratio) ogive values. This reference also indicates that the center-of-pressure location for 3/4-power bodies is approximately 5 percent of the body length ahead of the corresponding cone location. Figure 4.2.2.1-23a is recommended for 1/2-power bodies. For 3/4-power bodies it is recommended that figure 4.2.2.1-23b be used with the center-of-pressure location moved forward approximately 5 percent from the chart value.

The center-of-pressure location of a boattail at the end of a semi-infinite cylindrical body is presented in figure 4.2.2.1-24. This chart is taken from reference 9 and is based on the results of reference 10.

The moment slope of an ogive-cylinder or cone-cylinder body with a boattail afterbody, based on the product of the maximum frontal area and the length of the ogive-cylinder or cone-cylinder body $S_B\ell_B$, is (see sketch (b))

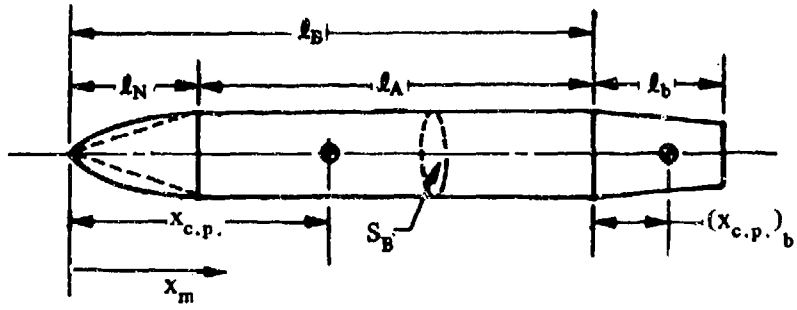
$$C_{m_\alpha} = (C_{m_\alpha})_{\substack{\text{ogive/cone-}\\\text{cylinder}}} + \left\{\frac{x_m}{\ell_B} - \left[\frac{(x_{c.p.})_b}{\ell_b}\frac{\ell_b}{\ell_B} + \left(1 - \frac{x_m}{\ell_B}\right)\right]\right\} \Delta C_{N_\alpha} \text{ (per radian)} \quad 4.2.2.1\text{-e}$$

where $(C_{m_\alpha})_{\substack{\text{ogive/cone-}\\\text{cylinder}}}$ is obtained from equation 4.2.2.1-d, x_m/ℓ_B is defined above, and

$\frac{(x_{c.p.})_b}{\ell_b}$ is the center-of-pressure location of the boattail in fraction of boattail length, measured aft of the forward face of the boattail. This parameter is obtained from figure 4.2.2.1-24.

$\frac{\ell_b}{\ell_B}$ is the ratio of the boattail length to the length of the ogive-cylinder or cone-cylinder body.

ΔC_{N_α} is the increment in normal-force-curve slope, based on S_B, due to the addition of a boattail to a semi-infinite cylindrical body. This parameter is obtained from paragraph C of Section 4.2.1.1 (figure 4.2.1.1-22a).



SKETCH (b)

The moment coefficient of a flared body of revolution is taken to be that predicted by impact theory.

The moment slope of an ogive-cylinder or cone-cylinder body with a flared afterbody, based on the product of the maximum frontal area and length of the ogive-cylinder or cone-cylinder body $S_B \ell_B$, is (see sketch (c))

$$C_{m_\alpha} = \left(C_{m_\alpha}\right)_{\substack{\text{ogive/cone-}\\\text{cylinder}}} + C'_{m_\alpha} \frac{d^3}{a^2 \ell_B} + \frac{n}{\ell_B}\left(\Delta C_{N_\alpha}\right)_F \text{ (per radian)} \qquad 4.2.2.1\text{-f}$$

where

$\left(C_{m_\alpha}\right)_{\substack{\text{ogive/cone-}\\\text{cylinder}}}$ is obtained from equation 4.2.2.1-d, and

C_{m_α} is the pitching-moment-curve slope of the flared afterbody about its own front face, based on the product of its base area and base diameter. This parameter is obtained from figure 4.2.2.1-25a.

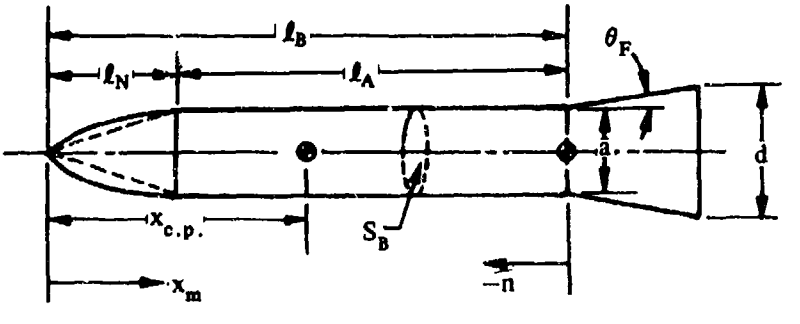
d is the diameter of the base of the flared body.

a is the diameter of the front face of the flared body.

ℓ_B is the length of the ogive-cylinder or cone-cylinder body.

n is the distance from the face of the flared afterbody to the desired moment reference axis of the configuration, positive aft.

$\left(\Delta C_{N_\alpha}\right)_F$ is the normal-force-curve-slope increment, based on S_B, due to the addition of a flared afterbody behind a semi-infinite cylinder. This parameter is obtained from paragraph C of Section 4.2.1.1 (figure 4.2.1.1-22b).



SKETCH (c)

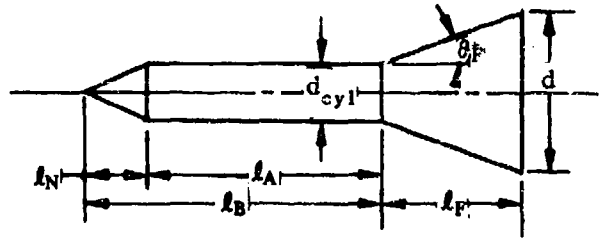
A comparison of test data with C_{m_α} of ogive-cylinder and cone-cylinder bodies calculated by this method is presented as table 4.2.2.1-A. The ranges of body geometry and Mach number of the test data are:

Cone-Cylinder	Ogive-Cylinder
$0 < f_A < 12$	$0 < f_A < 10$
$2.112 < f_N < 12$	$1.5 < f_N < 7$
$0 < f_A/f_N < 2.5$	$0 < f_A/f_N < 2.5$
$1.5 < M < 5.0$	$1.20 < M < 4.24$

No method is available for estimating the pitching-moment-curve slope of a body of noncircular cross section at supersonic speeds. Consequently, test data must be relied upon as the basis for predicting the pitching-moment-curve slope of such configurations. A summary of available test data on bodies of noncircular cross section at supersonic speeds is presented as table 4.2.1.1-C.

Sample Problem

Given: The cone-cylinder-flare body of reference 13. This is the same configuration as the sample problem of paragraph C of Section 4.2.1.1.



ℓ_N = 1.21 in. ℓ_A = 4.00 in. ℓ_B = 5.21 in.

ℓ_F = 2.40 in. $d_{cyl} = a_{flare}$ = 1.0 in.

$d_{flare} = d$ = 2.75 in. θ_F = 20°

n = −5.21 in. x_m = 0 M = 5.05; β = 4.95

Compute:

Cone-cylinder

$f_N = \ell_N/d_{cyl}$ = 1.21

$f_A = \ell_A/d_{cyl}$ = 4.00

$f_A/f_N = 4.00/1.21 = 3.31$

$f_N/\beta = 1.21/4.95 = 0.244$

$x_{c.p.}/\ell_B = 0.36$ (linear extrapolation) (figure 4.2.2.1-23b)

$C_{N_\alpha} = 3.52$ per rad (based on S_B) (sample problem, paragraph C, Section 4.2.1.1)

$$\left(C_{m_\alpha}\right)_{\substack{\text{cone-}\\\text{cylinder}}} = \left(\frac{x_m}{\ell_B} - \frac{x_{c.p.}}{\ell_B}\right) C_{N_\alpha} \quad \text{(equation 4.2.2.1-d)}$$

$$= (0 - 0.36)(3.52)$$

$$= -1.267 \text{ per rad (based on } S_B\ell_B)$$

Flare:

$\left(\Delta C_{N_\alpha}\right)_F = 11.73$ per rad (based on S_B) (sample problem, paragraph C, Section 4.2.1.1)

$n/\ell_B = -5.21/5.21 = -1.0$

$a/d = 1.0/2.75 = 0.364$

$C'_{m_\alpha} = -1.0$ per rad $\left(\text{based on } \frac{\pi d^3}{4}\right)$ (figure 4.2.2.1-25a)

Solution:

$$C_{m_\alpha} = \left(C_{m_\alpha}\right)_{\substack{\text{cone-}\\\text{cylinder}}} + C'_{m_\alpha} \frac{d^3}{a^2\ell_B} + \frac{n}{\ell_B}\left(\Delta C_{N_\alpha}\right)_F \quad \text{(equation 4.2.2.1-f)}$$

$$= -1.267 + (-1.0)\frac{(2.75)^3}{(1.0)^2(5.21)} + (-1.0)(11.73)$$

$$= -1.267 - 3.992 - 11.73$$

$$= -16.99 \text{ per rad (based on } S_B\ell_B)$$

This compares with a test value of -14.51 per radian from reference 13.

D. HYPERSONIC

Newtonian theory is used in this section to estimate the pitching-moment-curve slope of cone frustums with or without a spherical nose, a blunted conical nose, or a blunted ogival nose. Newtonian impact theory and its modifications are discussed in paragraph D of Section 4.2.1.1.

DATCOM METHOD

Charts that give the pitching-moment-curve slope of cone-frustum bodies and spherical noses are presented in figures 4.2.2.1-25a and 4.2.2.1-25b, respectively. These charts are taken from reference 11 and are based on Newtonian impact theory. By properly combining values from these charts, the total C_{m_α} may be determined for bodies composed of multiple cone frustums with or without spherically blunted noses.

The center-of-pressure locations of spherically blunted cones and ogives are presented in figures 4.2.2.1-26 and 4.2.2.1-27, respectively. These charts are also based on impact theory, and represent a specific application of the method described below for configurations consisting of cone frustums with spherical noses.

The procedure for computing the total pitching-moment-curve slope for a complex body is given in the following steps. The moment values for each individual segment of a multiple cone-frustum body with or without a spherical nose are referred to a moment axis at the front face of that particular segment, and are based on the product of the base area and base diameter of that particular segment.

Step 1. Compute C'_{m_α} for each body segment about its own front face, using figures 4.2.2.1-25a and 4.2.2.1-25b.

Step 2. Transfer the individual moment slopes to a common reference axis by applying the following moment transfer equation to each body segment.

$$C_{m_\alpha} = C'_{m_\alpha} + \frac{n}{d} C_{N_\alpha} \quad \text{(per radian)} \qquad 4.2.2.1\text{-g}$$

where

C_{N_α} is the normal-force-curve slope of the individual cone-frustum or spherical nose segment, based on its own base area, from figures 4.2.1.1-26 and 4.2.1.1-23, respectively.

d is the base diameter of the individual cone-frustum or spherical nose segment.

n is the distance from the front face of a given segment to the desired moment reference axis of the configuration, positive aft.

C'_{m_α} is the pitching-moment-curve slope of an individual segment from figure 4.2.2.1-25a for cone frustums and from figure 4.2.2.1-25b for spherical nose segments. C'_{m_α} is based on the product of the base area and the base diameter of the individual segment.

C_{m_α} is the pitching-moment-curve slope of an individual segment based on the product of the base area and base diameter of the individual segment and referred to a common reference axis.

Step 3. The transferred pitching-moment-curve slopes of the individual body segments are then converted to a common basis by

$$C_{m_\alpha} = \sum_{n=1}^{m} \left(C_{m_\alpha}\right)_n \left(\frac{d_n}{d_b}\right)^3 \quad \text{(per radian)} \qquad 4.2.2.1\text{-h}$$

where the subscript n refers to an individual segment of m segments, and C_{m_α} is referred to a common reference axis and is based on the product of the area and diameter of the base of the configuration $S_b d_b$.

In using figures 4.2.2.1-26 and 4.2.2.1-27 to obtain the pitching-moment-curve slope of spherically blunted cones and ogives, respectively, use is made of equation 4.2.2.1-d, i.e.,

$$C_{m_\alpha} = \left(\frac{x_m}{\ell_B} - \frac{x_{c.p.}}{\ell_B}\right) C_{N_\alpha} \quad \text{(per radian)}$$

where

$\frac{x_{c.p.}}{\ell_B}$ is obtained from figure 4.2.2.1-26 for spherically blunted cones and from figure 4.2.2.1-27 for spherically blunted ogives.

$\frac{x_m}{\ell_B}$ is the desired moment-center location in fraction of body length.

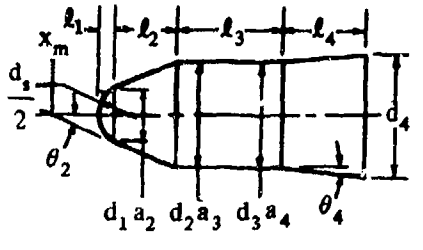
C_{N_α} is the normal-force-curve slope of spherically blunted cones and spherically blunted ogives from figures 4.2.1.1-24 and 4.2.1.1-25, respectively.

C_{m_α} is the pitching-moment-curve slope, referred to a desired moment axis and based on the product of the maximum frontal area and body length $S_B \ell_B$.

Values of C_{m_α} computed by the above method for spherically blunted cones and ogives may be used in conjunction with the results presented for conical-frustum bodies in figure 4.2.2.1-25a, provided the individual results are transferred to a common reference axis and converted to a common basis.

Sample Problem

Given: Configuration 5115 of reference 14, consisting of a cone-cylinder-frustum body with a spherical nose. This is the same configuration as the sample problem in paragraph D of Section 4.2.1.1.



(All dimensions are in feet. x_m located 0.55 ft forward of nose.)

Spherical Segment

$\ell_1 = 0.18 \qquad \frac{d_s}{2} = 0.36 \qquad d_1 = 0.62$

Forward Cone Frustum

$a_2 = 0.62 \qquad d_2 = 1.20 \qquad \ell_2 = 0.72$

$\theta_2 = 22.5^o$

Cylinder

$a_3 = 1.20 \quad d_3 = 1.20 \quad \ell_3 = 1.20 \quad \theta = 0$

Rear Cone Frustum

$a_4 = 1.20 \quad d_4 = d_b = 1.368 \quad \ell_4 = 0.96 \quad \theta_4 = 5^o$

Compute:

Spherical segment

$2\ell_1/d_s = 0.18/0.36 = 0.50$

$C'_{m_{\alpha_1}}$ = −0.430 per rad (figure 4.2.2.1-25b) (based on $\left(\frac{\pi d_1^2}{4}\right) d_1$, and taken about its front face)

$n_1 = -0.55$

$C_{N_{\alpha_1}}$ = 0.75 per rad $\left(\text{based on } \frac{\pi d_1^2}{4}\right)$ (sample problem, paragraph D, Section 4.2.1.1)

$C_{m_{\alpha_1}} = C'_{m_{\alpha_1}} + \frac{n_1}{d_1} C_{N_{\alpha_1}}$ (equation 4.2.2.1-g)

$= -0.430 + \left(\frac{-0.55}{0.62}\right) 0.75$

$= -1.095$ per rad (based on $\left(\frac{\pi d_1^2}{4}\right) d_1$, and taken about x_m)

Forward Cone Frustum

$a_2/d_2 = 0.62/1.20 = 0.517$

$C'_{m_{\alpha_2}}$ = −0.590 per rad (figure 4.2.2.1-25a) (based on $\left(\frac{\pi d_2^2}{4}\right) d_2$, and taken about its front face)

$n_2 = -(0.55 + \ell_1) = -0.73$

$C_{N_{\alpha_2}}$ = 1.250 per rad $\left(\text{based on } \frac{\pi d_2^2}{4}\right)$ (sample problem, paragraph D, Section 4.2.1.1)

$$C_{m_{\alpha_2}} = C'_{m_{\alpha_2}} + \frac{n_2}{d_2} C_{N_{\alpha_2}} \quad \text{(equation 4.2.2.1-g)}$$

$$= -0.590 + \left(\frac{-0.73}{1.20}\right) 1.250$$

$$= -1.350 \text{ per rad (based on } \left(\frac{\pi d_2^{\,2}}{2}\right) d_2, \text{ and taken about } x_m)$$

Cylinder

$a_3/d_3 = 1.20/1.20 = 1.00$

$C'_{m_{\alpha_3}} = 0$ (figure 4.2.2.1-25a)

$n_3 = -(0.55 + \ell_1 + \ell_2) = -1.45$

$C_{N_{\alpha_2}} = 0$ (sample problem, paragraph D, Section 4.2.1.1)

$$C_{m_{\alpha_3}} = C'_{m_{\alpha_3}} + \frac{n_3}{d_3} C_{N_{\alpha_3}} = 0 \quad \text{(equation 4.2.2.1-g)}$$

Rear Cone Frustum

$a_4/d_4 = 1.20/1.368 = 0.877$

$C'_{m_{\alpha_4}} = -0.325$ per rad (figure 4.2.2.1-23a) (based on $\left(\frac{\pi d_b^{\,2}}{4}\right) d_b$, and taken about its front face)

$n_4 = -(0.55 + \ell_1 + \ell_2 + \ell_3) = -2.65$

$C_{N_{\alpha_4}} = 0.450$ per rad $\left(\text{based on } \frac{\pi d_b^{\,2}}{4}\right)$ (sample problem, paragraph D, Section 4.2.1.1)

$$C_{m_{\alpha_4}} = C'_{m_{\alpha_4}} + \frac{n_4}{d_4} C_{N_{\alpha_4}} \quad \text{(equation 4.2.2.1-g)}$$

$$= -0.325 + \left(\frac{-2.65}{1.368}\right) 0.450$$

$$= -1.196 \text{ per rad (based on } \left(\frac{\pi d_b^{\,2}}{4}\right) d_b, \text{ and taken about } x_m)$$

Solution: $= \sum_{n=1}^{m} (C_{m_\alpha})_n \left(\frac{d_n}{d_b}\right)^3$ (equation 4.2.2.1-h)

$$C_{m_\alpha} = (C_{m_\alpha})_1 \left(\frac{d_1}{d_b}\right)^3 + (C_{m_\alpha})_2 \left(\frac{d_2}{d_b}\right)^3 + (C_{m_\alpha})_3 \left(\frac{d_3}{d_b}\right)^3 + (C_{m_\alpha})_4 \left(\frac{d_4}{d_b}\right)^3$$

$$= (-1.095) \left(\frac{0.62}{1.368}\right)^3 + (-1.350) \left(\frac{1.20}{1.368}\right)^3 + 0 \left(\frac{d_3}{d_b}\right)^3 + (-1.196) \left(\frac{1.368}{1.368}\right)^3$$

$$= -0.1019 - 0.9112 + 0 - 1.196$$

$= -2.209$ per rad (based on $\left(\frac{\pi d_b^2}{4}\right) d_b$, and referred to a moment axis at x_m)

4.2.2.2 BODY PITCHING MOMENT IN THE NONLINEAR ANGLE-OF-ATTACK RANGE

A. SUBSONIC

Two methods are presented for calculating subsonic pitching-moment coefficient. The first method is applicable to bodies with circular cross sections and angles of attack up to about 12°. This method allows for a variation of the cross-sectional diameter along the length of the body. The second method is applicable to bodies with circular or elliptical cross sections for angles of attack from 0 to 180°. This method has been substantiated only for bodies with a constant cross-sectional size and shape.

DATCOM METHODS

Method 1

As discussed in Section 4.2.1.2, the viscous cross flow over a body at moderate to large angles of attack makes a substantial contribution to both lift and pitching moment. This method for predicting body pitching moment therefore differs chiefly from the method of Section 4.2.2.1 in that the viscous cross forces are considered.

The method of Reference 1 is presented for estimating the pitching moment of a body of revolution at angle of attack, based on the total body volume and referred to an arbitrary moment axis.

$$C_m = \frac{(k_2 - k_1)}{V_B} 2\alpha \int_0^{x_o} \frac{dS_x}{dx}(x_m - x)dx + \frac{2\alpha^2}{V_B} \int_{x_o}^{\ell_B} \eta r c_{d_c}(x_m - x)dx \qquad 4.2.2.2\text{-a}$$

where the terms in the above expression are defined in Paragraph A of either Section 4.2.1.2 or Section 4.2.2.1.

The pitching-moment coefficients of several bodies of revolution, calculated by the Datcom method, have been compared with test data in Reference 1. The method appears to give the best results at the lower angles of attack, but in general the method is satisfactory up to angles of attack of approximately 12°.

Method 2

This method is based on the method of Jorgensen (Reference 2) and consists of the sum of a slender-body potential term and an empirical viscous cross-flow term. The method is applicable to bodies of circular and elliptical cross sections for angles of attack from 0 to 180°. However, it is recommended that Method 1 be used for $\alpha \leqslant 12^{\circ}$. Bodies with other types of cross sections and those with variable cross sections have been investigated by this method (References 2 and 3), but very little substantiating test data are available. A summary of available test data on bodies of noncircular cross section at subsonic speeds is presented as Table 4.2.1.1-A.

The pitching-moment coefficient for bodies of revolution and bodies with elliptical cross sections, based on body cross-sectional reference area and diameter, is determined from the following equations:

For $0 \leqslant \alpha \leqslant 90^{o}$

$$C_m = \left(\frac{C_N}{C_{N_{cir}}}\right)_{SB} \left[\frac{V_B - S_b(\ell_B - x_m)}{Sd}\right] \sin 2\alpha' \cos\frac{\alpha'}{2} + \left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} \eta c_{d_c} \frac{S_p}{S}\left(\frac{x_m - x_c}{d}\right) \sin^2\alpha' \qquad 4.2.2.2\text{-b}$$

For $90^{o} \leqslant \alpha \leqslant 180^{o}$

$$C_m = -\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB} \left(\frac{V_B - S_b x_m}{Sd}\right) \sin 2\alpha' \cos\frac{\alpha'}{2} + \left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} \eta c_{d_c} \frac{S_p}{S}\left(\frac{x_m - x_c}{d}\right) \sin^2\alpha' \qquad 4.2.2.2\text{-c}$$

where

$\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB}$ is the ratio of the normal-force coefficient for the body of noncircular cross section to that for the equivalent body of circular cross section (same cross-sectional area) as determined by slender-body theory. For circular cross sections this ratio is one. For elliptical cross sections this ratio is given by Equation 4.2.1.2-d.

V_B is the total body volume.

S_b is the body base area.

ℓ_B is the body length.

x_m is the distance from the nose to the moment reference center of the body.

S is the cross-sectional reference area of the body (can be arbitrarily selected).

d is the body diameter (or the diameter of an equivalent body of revolution for an elliptic cross section).

α' is an incidence angle defined as $\alpha' = \alpha$ for $0 \leqslant \alpha \leqslant 90^{o}$ and $\alpha' = 180^{o} - \alpha$ for $90^{o} \leqslant \alpha \leqslant 180^{o}$.

$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT}$ is the ratio of the normal-force coefficient for the body of noncircular cross section to that for the equivalent body of circular cross section (same cross-sectional area) as determined by Newtonian impact theory. For circular cross sections this ratio is one. For elliptical cross sections this ratio is given by Equations 4.2.1.2-e and 4.2.1.2-f.

η is the cross-flow drag proportionality factor, obtained from Figure 4.2.1.2-35a, as a function of body fineness ratio.

c_{d_c} is the cross-flow drag coefficient of the cylindrical section, obtained from Figure 4.2.1.2-35b, as a function of cross-flow Mach number M_c, where $M_c = M \sin \alpha$.

S_p is the body planform area. In applying the method to bodies with elliptical cross section, the term S_p in Equations 4.2.2.2-b and 4.2.2.2-c is based on an equivalent body of revolution with the same cross-sectional area.

x_c is the distance from the nose to the centroid of the body planform area.

This method is applied to bodies of noncircular cross sections in the same manner as Method 3 of Section 4.2.1.2, Paragraph A. Refer to this paragraph for a more detailed explanation of bodies with elliptical cross sections. Bodies with other cross sections are discussed in Reference 3.

It is noted in Reference 2 that the cross-flow drag coefficient may be reduced dramatically under the simultaneous conditions of $M_c \leq 0.4$ and $R_\ell \sin \alpha > 10^5$ (R_ℓ is Reynolds number based on diameter). These conditions have only recently been analyzed in detail and have not been included in the Datcom method because of considerable uncertainty in the magnitude and trend of the effects. For more detailed information regarding these effects, the user should refer to Reference 2.

Calculated results using this method have been compared with test data from Reference 6 in Table 4.2.2.2-A. The method shows fairly good agreement at angles of attack up to 20°, but significantly underestimates the data at higher angles of attack. Caution should be exercised when using this method at subsonic Mach numbers because of the shortage of substantiating test data. It is recommended that Method 1 be used for $0 \leq \alpha \leq 12^\circ$.

Sample Problems

1. Method 1

Given: The 3/4-power body of revolution of Reference 10. This is the same configuration as that in Paragraph A of Section 4.2.2.1.

$$r = 0.255 \left[1 - \left(1 - \frac{2x}{6.375}\right)^2\right]^{3/4} \qquad \ell_B = 5.036 \text{ ft} \qquad d = 0.510 \text{ ft}$$

$$f = \ell_B/d = 9.87 \qquad V_B = 0.687 \text{ cu ft} \qquad x_m = 3.54 \text{ ft}$$

$$M = 0.40 \qquad \alpha = 0 \text{ to } 18^\circ$$

Compute:

$x_o = 4.558$ ft

$$\frac{2(k_2 - k_1)}{V_B} \int_0^{x_o} \frac{dS_x}{dx} (x_m - x)\, dx = 1.293 \text{ per rad}$$ (Sample Problem 2, Paragraph A, Section 4.2.2.1)

$\eta = 0.685$ (Figure 4.2.1.2-35a)

$c_{d_c} = f(M_c)$; $M_c = M \sin \alpha$

M_c varies from 0 to 0.40 sin 18°; $0 \leq M_c \leq 0.1236$

$c_{d_c} = 1.20$ (constant) (Figure 4.2.1.2-35b)

Evaluate $\int_{x_o}^{\ell_B} r\,(x_m - x)\, dx$

Station (ft)	r* (ft)	Δx (ft)	x* (ft)	$(x_m - x)$ ft	$r(x_m - x)\,\Delta x$ (ft^3)
$x_o = 4.56$	0.2037	0.476	4.79	−1.25	−0.121
$\ell_B = 5.036$					

$$\sum_{x_o}^{\ell_B} r(x_m - x)\,\Delta x = -0.121 \text{ cu ft}$$

Solution:

$$C_m = \frac{(k_2 - k_1)}{V_B}\, 2\alpha \int_0^{x_o} \frac{dS_x}{dx} (x_m - x)\, dx + \frac{2\alpha^2}{V_B} \int_{x_o}^{\ell_B} \eta r c_{d_c} (x_m - x)\, dx$$

(Equation 4.2.2.2-a)

$$= 1.293\alpha + \frac{2\alpha^2}{0.687} (0.685)(1.20) \int_{x_o}^{\ell_B} r(x_m - x)\, dx$$

$$= 1.293\alpha - 0.290\alpha^2$$

*x and r are taken at the center of volume of the body segment.

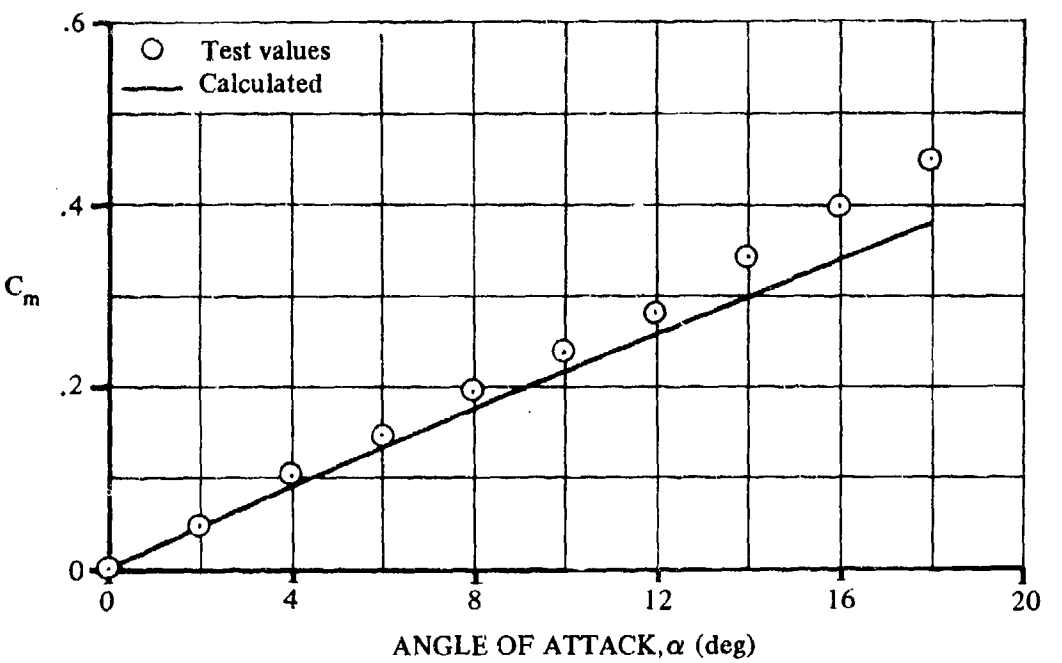
14	0.2443	0.05968	0.2986
16	0.2792	0.07795	0.3384
18	0.3141	0.09866	0.3775

The calculated results are compared with test values from Reference 15 in Sketch (a).



SKETCH (a)

2. Method 2

Given: The elliptical cross-section body with tangent ogive nose of Reference 6. This is the same configuration as given in the sample problem for Method 3 of Paragraph A of Section 4.2.1.2.

Body Characteristics:

$V_B = 1944.64\ cm^3$ $\quad x_c = 36.08\ cm$

$\ell_B = 66.0\ cm$ $\quad x_m = 39.58\ cm$ $\quad S_p = 392.466\ cm^2$

$d = 6.6\ cm$

$S = 34.206\ cm^2$

$S_b = 34.206\ cm^2$

$\left(\frac{C_N}{C_{N_{cir}}}\right)_{SB} = 2.0$

$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} = 1.752$

} Sample Problem 3, Paragraph A, Section 4.2.1.2

Additional Characteristics:

$\alpha' = \alpha = 50^o$ $\quad M = 0.6$ $\quad R_\ell = 6.5 \times 10^5$ (based on diameter)

$\phi = 0$

Compute:

Slender-body Potential Term

$\eta = 0.685$

$c_{d_c} = 1.32$

} Sample Problem 3, Paragraph A, Section 4.2.1.2

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{Sb} \left[\frac{V_B - S_b(\ell_B - x_m)}{Sd}\right] \sin 2\alpha' \cos\frac{\alpha'}{2}$$

$$= (2.0)\left[\frac{1944.64 - 34.206(66.0 - 39.58)}{(34.206)(6.6)}\right](0.9848)(0.9063) = 8.23$$

Viscous Cross-Flow Term

$$\left(\frac{C_N}{C_{N_{cir}}}\right)_{NT} \eta c_{d_c} \frac{S_p}{S}\left(\frac{x_m - x_c}{d}\right) \sin^2\alpha'$$

$$= (1.752)(0.685)(1.32)\left(\frac{392.466}{34.206}\right)\left(\frac{39.58 - 36.08}{6.6}\right)(0.5868) = 5.66$$

Solution:

C_m = slender-body potential term + viscous cross-flow term

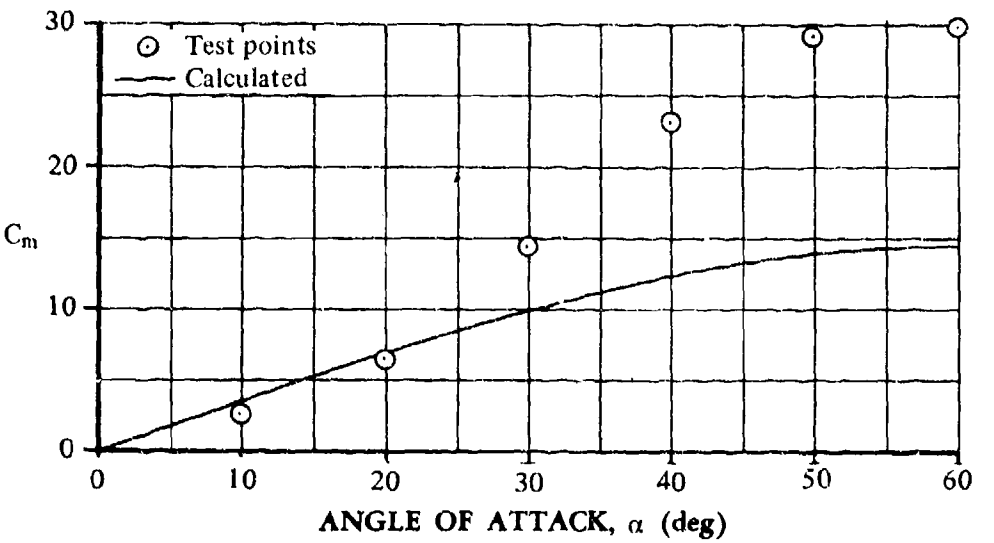
= 8.23 + 5.66

= 13.89 (based on Sd)

Additional values have been tabulated below:

M	α (deg)	C_m
0.6	10	3.41
0.6	20	6.87
0.6	30	9.94
0.6	40	12.34
0.6	50	13.89
0.6	60	14.51

The calculated results of the sample problem are compared to test values from Reference 6 in Sketch (b).



SKETCH (b)

B. TRANSONIC

Transonic flow, which consists by definition of a combination of locally subsonic and supersonic flow regions, is particularly difficult for either theoretical or empirical analysis. The two types of flow interact directly on their mutual boundaries and indirectly through the boundary layer. The resulting flow pattern is highly sensitive to seemingly small changes in geometry. Prediction of transonic body lift is at best an approximation; prediction of transonic body lift distribution is considerably more difficult.

DATCOM METHOD

Because of the difficulty of predicting transonic-flow phenomena to the accuracy required for lift distribution, no Datcom method is given for predicting body pitching moment at transonic speeds. It is suggested that the transonic region be faired smoothly from the subsonic region to the supersonic region.

C. SUPERSONIC

Several theoretical methods have been developed that can be used to estimate the moment characteristics of bodies of revolution at supersonic speeds. Some of these methods are discussed in Paragraph C of Section 4.2.1.2.

Three methods are presented for estimating body pitching moment at supersonic speeds. The first method is based on the method of Allen and Perkins (Reference 7) and includes a modification by Jorgensen (Reference 8) to accommodate bodies with elliptical cross sections. The second approach uses hypersonic-similarity concepts that have been adapted to supersonic speeds (Reference 9). These two methods are discussed in Paragraph C of Section 4.2.1.2. The third method is an improvement on Method 1 developed by Jorgensen in Reference 2. This method extends the capability for calculating pitching moments to 180°. The method is identical to that presented as Method 2 in Paragraph A of this section.

DATCOM METHODS

Method 1

The method presented for predicting the pitching moment of a body of revolution at angle of attack is that of Allen and Perkins, in Reference 7. The method for estimating the pitching moment of bodies of elliptical cross section is that of Reference 7 as modified by Jorgensen in Reference 8.

The pitching-moment coefficient of a body of revolution, based on body base area and body length $S_b \ell_B$ and referred to an arbitrary moment center, is

$$C_m = 2\alpha \left[\frac{V_B}{S_b \ell_B} - \left(1 - \frac{x_m}{\ell_B} \right) \right] + c_{d_c} \frac{S_p}{S_b} \left(\frac{x_m - x_c}{\ell_B} \right) \alpha^2 \qquad 4.2.2.2\text{-d}$$

where x_c is the axial distance from the vertex of the nose to the centroid of the planform area, and the remaining terms are defined in Paragraph C of either Section 4.2.1.2 or Section 4.2.2.1.

The supersonic pitching-moment coefficient at angle of attack of a body having an elliptical cross section, based on body base area and body length $S_b \ell_B$ and referred to an arbitrary moment center, is

$$(C_m)_{a/b} = \left[\frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi\right] C_m \qquad 4.2.2.2\text{-e}$$

where C_m is the pitching-moment coefficient of a body of revolution having the same cross-sectional area distribution along its axis as the elliptical-cross-section body of interest. It is given by Equation 4.2.2.2-d. The parameters a, b, and ϕ are defined in Paragraph C of Section 4.2.1.2.

The Datcom method has been used to calculate the variation of pitching-moment coefficient with angle of attack for the bodies of elliptic cross section of Reference 8 and for the bodies of revolution of References 7, 8, and 10 through 13. Although the nose shapes of most of the configurations analyzed were tangent ogives, a few bodies of revolution had conical or hemispherical noses. All the afterbodies were straight (no boattail or flare). In general, the calculated results agree well with the test data. The comparison of calculated and test values for the sample problems at the conclusion of this paragraph is indicative of the degree of accuracy of this method.

Method 2

This method uses hypersonic-similarity parameters that have been adapted to supersonic speeds by the method of Reference 9. This method is based on experimental data for a wide range of models for Mach numbers between 1.57 and 2.87. The variation of pitching-moment coefficient with angle of attack for pointed or nearly pointed bodies of revolution is estimated by using Figure 4.2.2.2-26 where $\beta = \sqrt{M^2 - 1}$. The body pitching moment obtained from this chart is referred to the nose apex and is based on the product of body frontal area and the body length $S_B \ell_B$.

A comparison of test data with the pitching-moment coefficient calculated by this method is presented as Table 4.2.2.2-B.

Method 3

This method is the same as Method 2 presented in Paragraph A of this section. The only exception is that the term η in Equations 4.2.2.2-b and 4.2.2.2-c is set equal to 1.0 for $M \geq 1.0$.

The method is applicable to angles of attack from 0 to 180° and Mach numbers up to 7. The method is substantiated by test data from References 4, 5, and 6 in Table 4.2.2.2-C.

The method shows reasonable agreement with most test data, but Methods 1 and 2 are recommended in the low-angle-of-attack range.

With the exception of bodies with elliptical cross sections, there are no Datcom methods for predicting the pitching moment on bodies of noncircular cross section at supersonic speeds. A summary of available test data on bodies of noncircular cross section at supersonic speeds is presented as Table 4.2.1.1-C. In

Reference 8 (Reference 37 of Table 4.2.1.1-C) the effect of cross-sectional shape on body aerodynamics has been assessed for bodies with circular, elliptic, square, and triangular cross sections. These data show that at certain angles of bank, noncircular bodies develop considerably more pitching moment than their equivalent bodies of revolution at a given angle of attack. The data of Reference 8 also show that the ratio of pitching-moment coefficient for a body with elliptic cross section to that for an equivalent body of revolution is practically constant with change in both angle of attack and Mach number. However, no such simple correlation is available for other bodies of noncircular cross section. Method 3 has been applied to other bodies with noncircular and axially varying cross sections by Jorgensen in References 2 and 3. The lack of sufficient substantiating data has precluded inclusion of this application in the Datcom.

Sample Problems

1. Method 1

Given: An ogive-cylinder body of Reference 8. This is the same configuration as that of Sample Problem 1 of Paragraph C of Section 4.2.1.2.

Body Characteristics:

$d = 1.40$ in. $\quad \ell_B = 14.0$ in. $\quad \ell_N = 4.20$ in. $\quad \ell_A = 9.80$ in.

$V_B = 18.56$ cu in. $\quad S_b = 1.539$ sq in. $\quad S_p = 17.66$ sq in.

$S_p/S_b = 11.47 \quad x_c = 7.69$ in. $\quad x_m/\ell_B = 1.0$ (moments referred to body base)

Additional Characteristics:

$M = 1.98 \quad \alpha = 4^o, 8^o, 12^o, 16^o, 20^o$

Compute:

$c_{d_c} = f(M_c) = f(M \sin\alpha)$

α	4^o	8^o	12^o	16^o	20^o	(Sample Problem 1, Paragraph C, Section 4.2.1.2)
c_{d_c}	1.20	1.208	1.275	1.41	1.62	

$$\left[\frac{V_B}{S_b \ell_B} - \left(1 - \frac{x_m}{\ell_B}\right)\right] = \left[\frac{18.56}{(1.539)(14.0)} - (1 - 1.0)\right] = 0.8614$$

$$c_{d_c} \frac{S_p}{S_b} \left(\frac{x_m - x_c}{\ell_B}\right) = c_{d_c} (11.47) \left(\frac{14.0 - 7.69}{14.0}\right) = 5.170\, c_{d_c}$$

Solution:

$$C_m = 2\alpha\left[\frac{V_B}{S_b \ell_B} - \left(1 - \frac{x_m}{\ell_B}\right)\right] + c_{d_c}\frac{S_p}{S_b}\left(\frac{x_m - x_c}{\ell_B}\right)\alpha^2 \quad \text{(Equation 4.2.2.2-d)}$$

$$= 2\alpha(0.8614) + 5.170\, c_{d_c}\alpha^2$$

$$= 1.723\alpha + 5.170\, c_{d_c}\alpha^2$$

α (deg)	α (rad)	α^2 (rad^2)	c_{d_c}	1.723α	$5.170\, c_{d_c}\alpha^2$	C_m Eq. 4.2.2.2-d (based on $S_b\ell_B$)
4	0.0698	0.00487	1.20	0.1203	0.0302	0.151

16	0.2793	0.07798	1.41	0.4812	0.5685	1.050
20	0.3491	0.12185	1.62	0.6015	1.0205	1.622

2. Method 1

Given: A body of Reference 8 having an elliptical cross section and the same axial distribution of cross-sectional area as the body of revolution of Sample Problem 1.

Body Characteristics:

a = 1.98 in. b = 0.99 in. a/b = 2.0 φ = 0

x_m/ℓ_B = 1.0 (moments referred to body base)

Additional Characteristics:

M = 1.98 α = 4°, 8°, 12°, 16°, 20°

Compute:

C_m vs α for a body of revolution having the same cross sectional area distribution and with the moment axis located at the base of the body. (from Sample Problem 1)

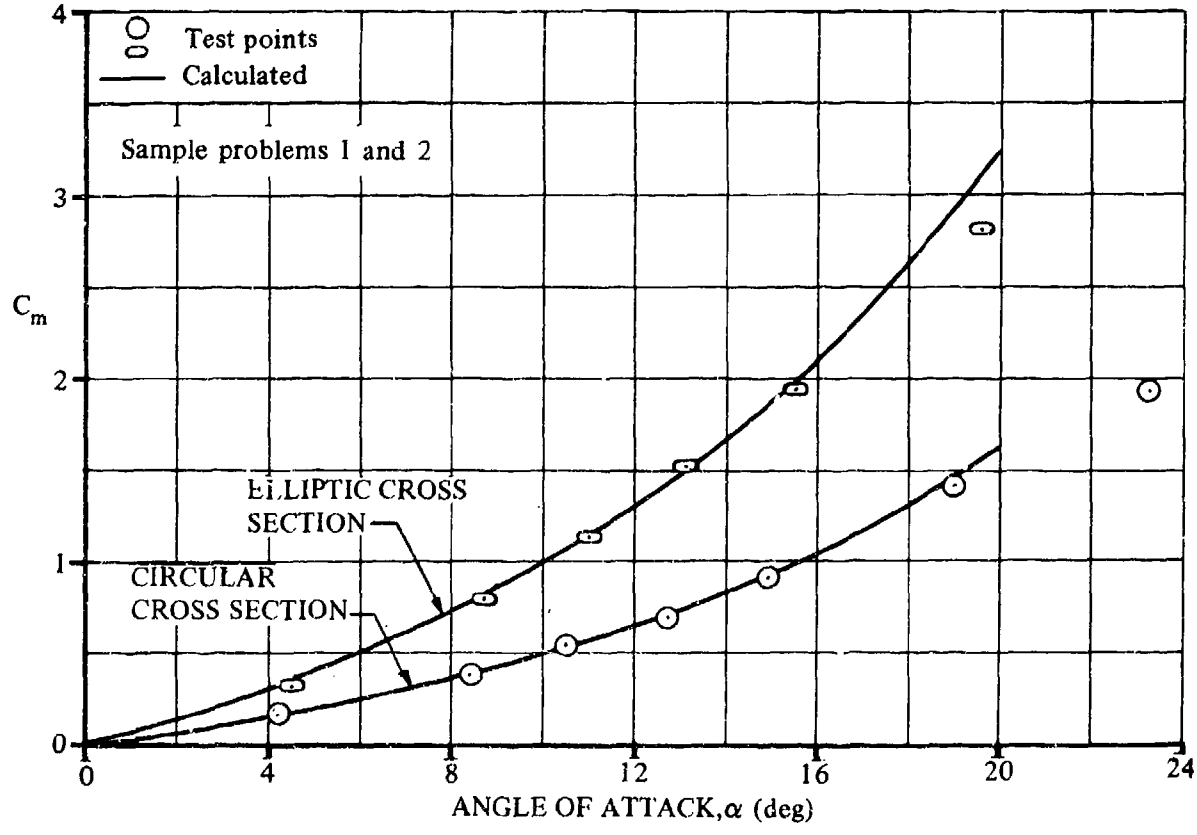
Solution:

$$C_m = \left[\frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi\right] C_m \qquad \text{(Equation 4.2.2.2-e)}$$

$$= [(2.0)(1.0) + 0]\, C_m = 2.0\, C_m$$

α (deg)	C_m Sample Problem 1	$(C_m)_{a/b}$ Eq. 4.2.2.2-e (based on $S_b \ell_B$)
4	0.151	0.302
8	0.362	0.724
12	0.650	1.300
16	1.050	2.100
20	1.622	3.244

The calculated results of Sample Problems 1 and 2 are compared with test values from Reference 8 in Sketch (c)



SKETCH (c)

3. Method 2

Given: The ogive-cylinder body of Sample Problem 1.

Body Characteristics:

$d = 1.40$ in. $\quad \ell_N = 4.20$ in. $\quad \ell_A = 9.80$ in.

Additional Characteristics:

$M = 1.98; \quad \beta = 1.71 \quad \alpha = 4^o, 8^o, 12^o$

Compute:

$f_N = \ell_N/d = 4.2/1.4 = 3.0 \quad f_A = \ell_A/d = 9.8/1.4 = 7.0$

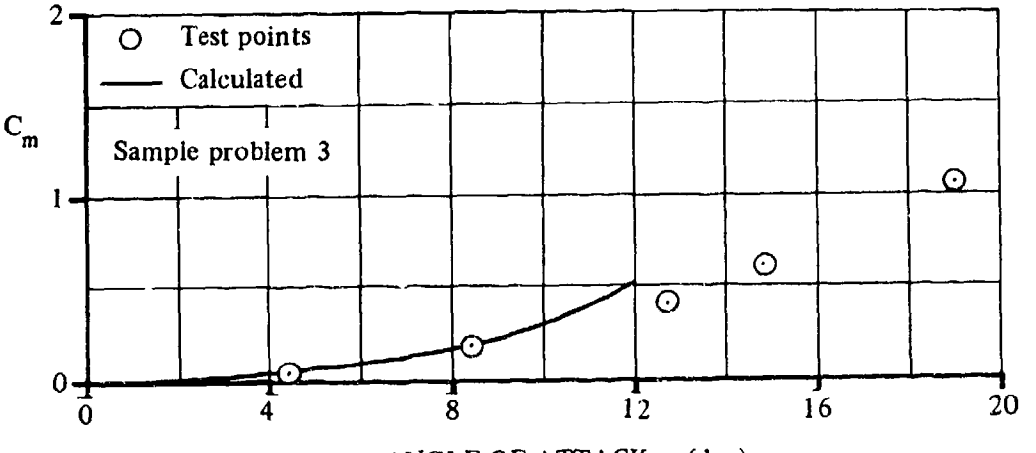
$f_A/f_N = 7.0/3.0 = 2.33$

$\beta/f_N = 1.71/3.0 = 0.570$

Solution:

α (deg)	$\beta\alpha$ (deg)	βC_m Fig. 4.2.2.2-26	C_m (based on $S_B\ell_B$) (referred to nose apex)
4	6.84	−0.073	−0.043
8	13.68	−0.275	−0.161
12	20.52	−0.930	−0.544

The calculated results are compared with test values from Reference 8 in Sketch (d). (The test results have been transferred to a moment axis at the nose apex).



SKETCH (d)

4. Method 3

Refer to Sample Problem 2 in Paragraph A of this section for an example of the application of the method.

D. HYPERSONIC

Three methods are available for estimating the pitching moment of bodies of revolution at hypersonic speeds. The first method, based on Newtonian impact theory and its modifications, is discussed in Paragraph D of Section 4.2.1.1. The second method is the hypersonic-similarity method. The third method is the method of Jorgensen previously presented as Method 3 of Paragraph C of this section.

DATCOM METHODS

Method 1

The expression for the pitching moment of an arbitrary body of revolution, from the modified Newtonian theory of Reference 14, referred to an arbitrary moment center and based on the product of the body base area and body length $S_B \ell_B$, is

$$C_m = \frac{K}{\pi} \frac{\ell_B}{R} \int_0^1 K_\theta \frac{r}{R} \frac{\ell_x}{\ell_B} \, d\left(\frac{x}{\ell_B}\right) \qquad 4.2.2.2\text{-f}$$

where ℓ_x is the distance from the moment center to a transverse element, positive where the element is forward of the moment center. The remaining parameters are defined under Method 2 in Paragraph D of Section 4.2.1.2.

The following steps outline the calculation procedure (Steps 1 through 3 are identical to Steps 1 through 3 of Method 2 of Paragraph D of Section 4.2.1.2):

Step 1. From the equation of the body of revolution obtain the expression for the surface slope using the relation

$$\theta = \tan^{-1}\left(\frac{dr}{dx}\right)$$

where θ, dr, and dx are defined in Sketch (f) of Section 4.2.1.2.

Step 2. Compute the values of r/R and θ at various longitudinanal stations x/ℓ_B.

Step 3. For various x/ℓ_B enter Figure 4.2.1.2-43 with the corresponding θ from Step 2 and obtain K_θ at the desired angle of attack.

Step 4. Plot the product $K_\theta \frac{r}{R} \frac{\ell_x}{\ell_B}$ against x/ℓ_B.

Step 5. Obtain the required value of C_m by integrating the area under the curve described in Step 4 and multiplying by $\frac{K}{\pi} \frac{\ell_B}{R}$.

Method 2

The second method of estimating body pitching moments applies only to ogive-cylinder bodies. This method is based on experimental data for a wide range of models at a Mach number of 4.24. These data have been used to derive a hypersonic design chart (Figure 4.2.2.2-27) based on hypersonic-similarity parameters. The body pitching moment obtained from Figure 4.2.2.2-27, where $\beta = \sqrt{M^2 - 1}$, is referred to the nose apex and is based on the product of the body frontal area and body length $S_B \ell_B$.

Pitching moments calculated by this method are compared with test data in Table 4.2.2.2-D.

Method 3

This method is identical to Method 3 presented in Paragraph C of this section. The method is applicable to angles of attack from 0 to 180° and Mach numbers up to 7. The method has been partially substantiated by the test data from Reference 5 in Table 4.2.2.2-C.

The method shows reasonable agreement with test data at hypersonic speeds in the low-angle-of-attack range. Because of the scarcity of substantiating test data, caution should be used when applying the method at higher angles of attack ($\alpha > 25^\circ$).

Sample Problems

1. Method 1

Given: A second-power body of revolution of fineness ratio 1.0. This is the same configuration as Sample Problem 2 of Paragraph D of Section 4.2.1.2.

$x = \left(\frac{4}{\ell_B}\right) r^2$ (equation of body) $\quad \ell_B = 2.0$ ft $\quad R = 1.0$ ft

$\ell_x/\ell_B = 0.50 - (x/\ell_B)$ (moment center at $0.50\ell_B$)

$M_\infty = 3.55 \quad \alpha = 6^\circ \quad \gamma = 1.40$

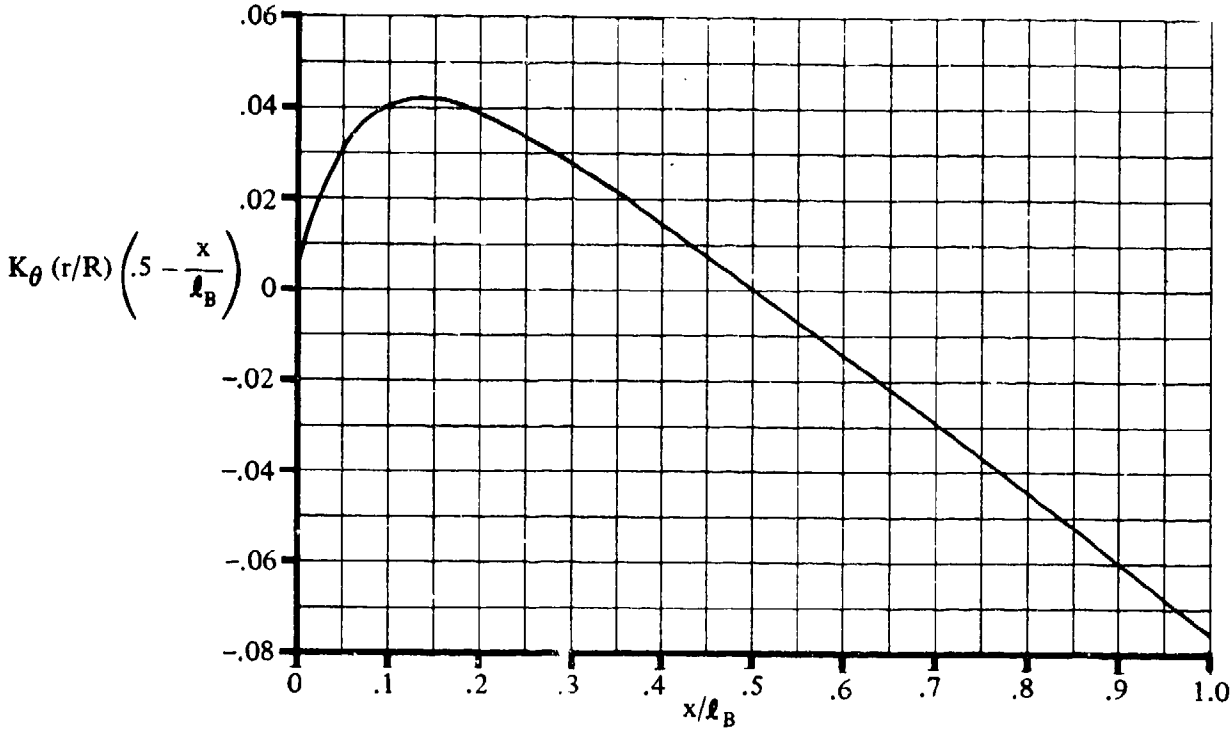
$K = 1.77$ (Sample Problem 2, Paragraph D, Section 4.2.1.2)

Compute:

Calculate r/R and θ at various longitudinal stations x/ℓ_B and plot. (See Sketch (g), Sample Problem 2, Paragraph D, Section 4.2.1.2.)

Obtain values of K_θ from Figure 4.2.1.2-43 for various values of θ at $\alpha = 6^\circ$.

Plot the product $K_\theta \frac{r}{R} \frac{\ell_x}{\ell_B}$ versus x/ℓ_B (Sketch (e)).



SKETCH (e)

Integrate the area under the curve of Sketch (e).

$$\int_0^1 K_\theta \frac{r}{R}\left(0.50 - \frac{x}{\ell_B}\right) d\left(\frac{x}{\ell_B}\right) = -0.00615$$

Solution:

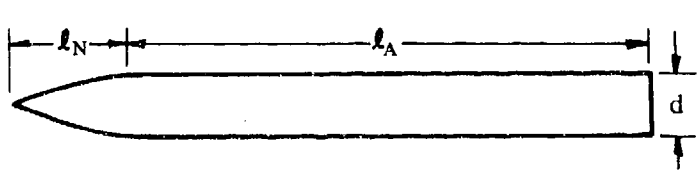
$$C_m = \frac{K}{\pi}\frac{\ell_B}{R}\int_0^1 K_\theta \frac{r}{R}\frac{\ell_x}{\ell_B}\, d\left(\frac{x}{\ell_B}\right) \quad \text{(Equation 4.2.2.2-f)}$$

$$= \frac{1.77}{\pi}\frac{2}{1}\,(-0.00615)$$

$$= -0.0069 \quad \text{(referred to a moment center at } 0.50\,\ell_B \text{ and based on } S_b\ell_B\text{)}$$

2. Method 2

Given: An ogive-cylinder body of Reference 16.



Body Characteristics:

ℓ_N = 2.50 ft ℓ_A = 11.50 ft d = 1.0 ft

Additional Characteristics:

M = 4.24; β = 4.12 α = 2°, 4°, 6°

Compute:

$f_N = \ell_N/d = 2.50$ $f_A = \ell_A/d = 11.50$

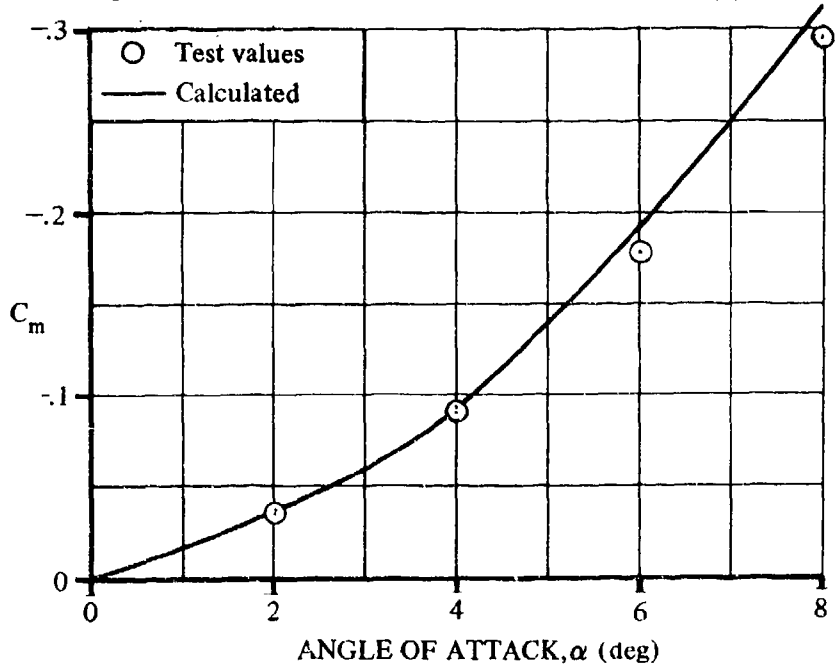
$f_A/f_N = 11.50/2.50 = 4.60$ $\beta/f_N = 4.12/2.50 = 1.648$

Solution:

α (deg)	$\beta\alpha$ (deg)	βC_m Fig. 4.2.2.2-27	C_m (based on $S_B\ell_B$) (referred to nose apex)
2	8.24	−0.15	−0.0364
4	16.48	−0.38	−0.0922
6	24.72	−0.79 (extrapolated)	−0.1917
8	32.96	−1.29 (extrapolated)	−0.3131

The calculated results are compared with test values from Reference 15 in Sketch (f).

SKETCH (f)



3. Method 3

Refer to Sample Problem 2 in Paragraph A of this section for an example of the application of the method.

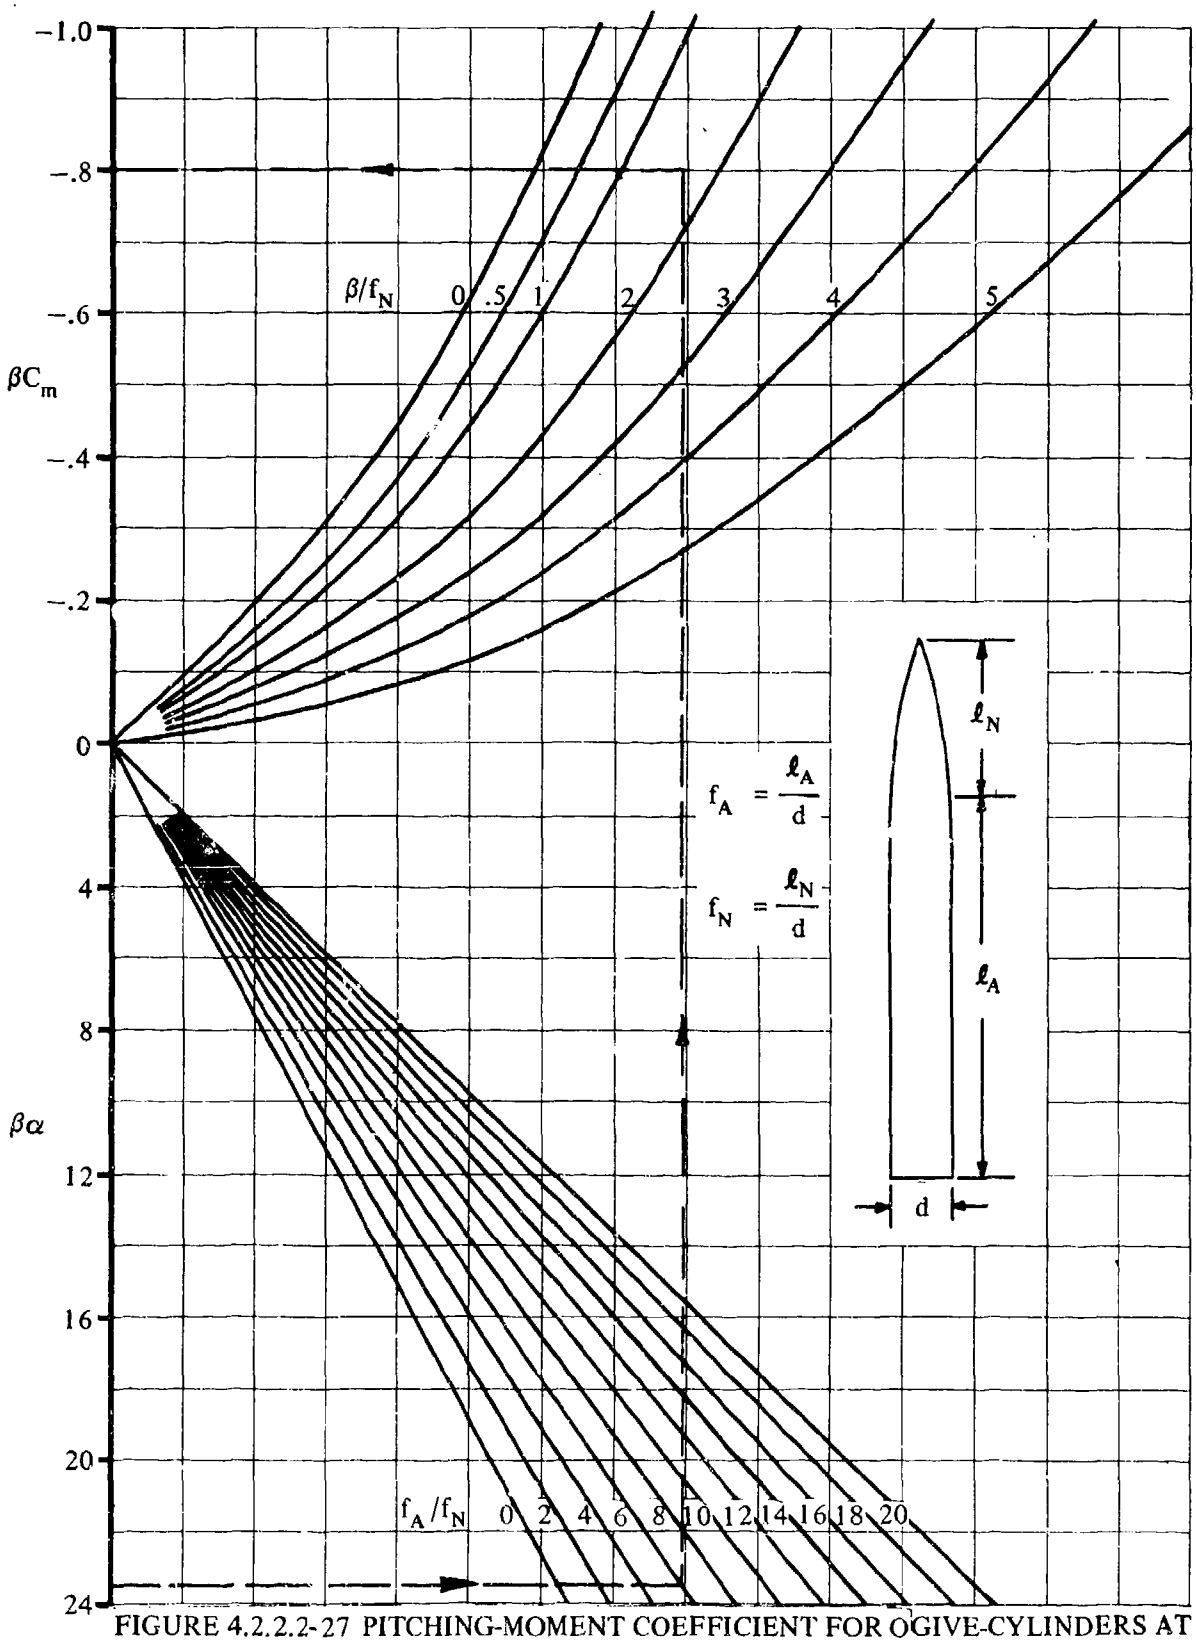

FIGURE 4.2.2.2-27 PITCHING-MOMENT COEFFICIENT FOR OGIVE-CYLINDERS AT HYPERSONIC SPEEDS $3.0 < M < 5.0$

4.2.3 BODY DRAG

4.2.3.1 BODY ZERO-LIFT DRAG

The composition of body zero-lift drag in the various speed regimes is very similar to that for wings (see Section 4.1.5.1). At subsonic speeds the pressure drag of the forebody is generally small and the total drag is composed mostly of skin friction and base drag. For the higher speed regimes the total drag is split significantly between friction and pressure drag.

The methods presented in this section are valid for bodies of revolution. However, excellent approximations can be made for non-body-of-revolution configurations by treating the equivalent body of revolution; that is, the body of revolution that has the same axial area distribution as the actual body.

A. SUBSONIC

At subsonic speeds the total zero-lift drag of smooth slender bodies is primarily skin friction. The Reynolds number based on body length, boundary-layer condition (laminar or turbulent), and surface roughness are important in the determination of the friction drag (see chapter VI of reference 1). For the Datcom these effects are handled the same as for wings (Section 4.1.5.1). A turbulent boundary-layer condition is assumed over the entire body surface.

The pressure drag of a closed body is zero for an inviscid fluid. Actually the displacement of the boundary layer causes an incomplete pressure recovery at the end of the body and a finite pressure drag results. This drag is small for fineness ratios above approximately four but becomes significant for blunt bodies.

The base drag is also generally small, usually less than 10 percent of the total body drag. The most popular approach to the estimation of base drag is to correlate it with the skin-friction drag of the remainder of the body. This approach is discussed in detail in reference 2 and in chapter VI of reference 1. Reference 3 shows that the presence of a wing increases the base pressure (less drag). Tail fins and wind-tunnel stings have the same effect (reference 4). Base pressures are also increased at low Reynolds numbers (reference 5).

DATCOM METHOD

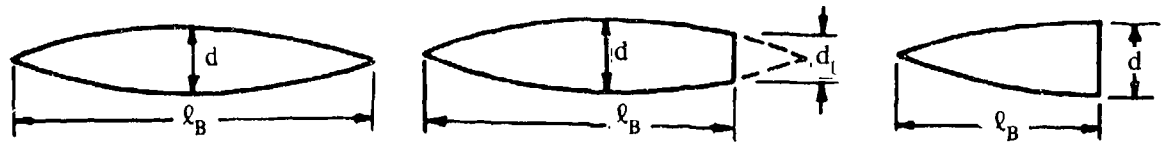
The subsonic zero-lift drag of an isolated body based on the maximum body frontal area is given in reference 6 as

$$C_{D_0} = C_f \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025 \left(\frac{\ell_B}{d}\right) \right] \frac{S_S}{S_B} + C_{D_b} \qquad 4.2.3.1\text{-a}$$

where the first term on the right-hand side of the equation is the zero-lift drag of the body exclusive of the base drag, and

C_f is the turbulent flat-plate skin-friction coefficient, including roughness effects, as a function of Mach number and the Reynolds number based on the reference length ℓ. This value is obtained from figure 4.1.5.1-26 and is determined as discussed in paragraph A of Section 4.1.5.1. The reference length ℓ is the actual length of the body ℓ_B.

$\frac{\ell_B}{d}$ is the body fineness ratio defined for different types of bodies of revolution as follows:



CLOSED BODY BODY HAVING A BLUNT BASE FOREBODY

For non-body-of-revolution configurations the equivalent diameter should be used,

$$d_{equiv} = \sqrt{\frac{\text{cross-sectional area}}{0.7854}}$$

C_{D_b} is the base-drag coefficient, based on the maximum body frontal area, given in reference 1 as

$$C_{D_b} = 0.029 \left(\frac{d_b}{d}\right)^3 \Big/ \sqrt{\left(C_{D_f}\right)_b} \qquad 4.2.3.1\text{-b}$$

where

$\frac{d_b}{d}$ is the ratio of base diameter to maximum diameter (equivalent diameters for non-body-of-revolution configurations).

$\left(C_{D_f}\right)_b$ is the zero-lift drag of the body exclusive of the base as determined by the first term in equation 4.2.3.1-a.

It should be noted that wings or fins (or wind-tunnel stings) can have a sizable effect on base drag.

S_B is the body maximum frontal area.

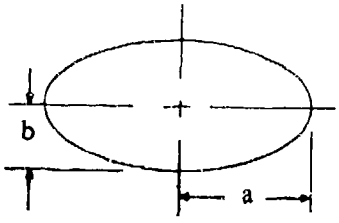
S_S is the wetted area or surface area of the body excluding the base area. This is normally determined by graphical integration of $\int_0^{\ell_B} p\,dx$, where p is the cross-section perimeter.

The ratio S_S/S_B for a given body can be approximated by using figures 2.3-2 and 2.3-3, which give this ratio for a number of specific body shapes.

The term $0.0025 \frac{\ell_B}{d}$ in equation 4.2.3.1-a represents the pressure-drag contribution.

Sample Problem

Given: The body of reference 54 having an elliptical cross section with a cutoff afterbody.



BODY CROSS SECTION
a/b = 3

ℓ_B = 61.45 in. a_{max} = 5.19 in. b_{max} = 1.73 in.

$S_b = 0.25\ S_B$

M = 0.8 $R_\ell = 0.325 \times 10^6$ per in.

Polished metal surface; assume $k = 0.08 \times 10^{-3}$ in.

Compute:

$S_B = \pi ab = \pi(5.19)(1.73) = 28.2$ sq in.

$d_{equiv} = \sqrt{\frac{S_B}{0.7854}} = \sqrt{\frac{28.2}{0.7854}} = 6.0$ in.

$\frac{\ell_B}{d} = \frac{61.45}{6.0} = 10.24$

$\frac{S_S}{S_B} = 31.6$ (extrapolated from figure 2.3-2, ellipsoid with cutoff afterbody)

$R_\ell = (0.325 \times 10^6)(\ell_B) = (0.325 \times 10^6)(61.45) = 1.997 \times 10^7$

$\ell/k = 61.45/(0.08 \times 10^{-3}) = 7.68 \times 10^5$; cutoff $R_\ell = 6.8 \times 10^7$ (figure 4.1.5.1-27)

Since cutoff R_ℓ > calculated R_ℓ, read C_f at calculated R_ℓ.

$C_f = 0.00256$ (figure 4.1.5.1-26)

Determine the zero-lift drag of the body exclusive of base drag.

$$\left(C_{D_f}\right)_b = C_f \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\left(\frac{\ell_B}{d}\right)\right]\frac{S_S}{S_B} = 0.00256\left[1 + \frac{60}{(10.24)^3} + 0.0025\,(10.24)\right] 31.6$$

$= 0.0875$ (based on S_B)

$S_b = 0.25\, S_B = (0.25)(28.2) = 7.05$ sq in.

$(d_b)_{equiv} = \sqrt{\frac{S_b}{0.7854}} = \sqrt{\frac{7.05}{0.7854}} = 3.0$ in.

$\frac{d_b}{d} = \frac{3.0}{6.0} = 0.5$

Determine the base drag

$$C_{D_b} = 0.029\left(\frac{d_b}{d}\right)^3 \Big/ \sqrt{\left(C_{D_f}\right)_b} \quad \text{(equation 4.2.3.1-b)}$$

$= 0.029\,(0.5)^3 \,/\, \sqrt{0.0875}$

$= 0.0122$ (based on S_B)

Solution:

$$C_{D_0} = C_f \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\left(\frac{\ell_B}{d}\right)\right]\frac{S_S}{S_B} + C_{D_b} \quad \text{(equation 4.2.3.1-a)}$$

$$= 0.0875 + 0.0122$$

$$= 0.0997 \text{ (based on } S_B\text{)}$$

This compares with a test value of 0.0920 from reference 54.

B. TRANSONIC

A fundamental discussion of the transonic aerodynamic characteristics of bodies is given in reference 7 and chapter XVI of reference 1. An extensive bibliography on finned bodies is given in reference 8.

For the Datcom, the general approach consists of predicting the skin friction, the drag-divergence Mach number, and the variation of base drag with Mach number, and the variation of pressure drag for Mach numbers above 1.0. The total drag characteristic as a function of Mach number is then constructed from these estimated characteristics. For the purpose of the Datcom the skin-friction drag is assumed to be constant and equal to the subsonic value at M = 0.6 throughout the transonic range.

DATCOM METHOD

The transonic zero-lift drag coefficient of a body is determined by the following procedure.

Step 1. Calculate the skin-friction drag coefficient at M = 0.6, based on maximum frontal area, by

$$C_{D_f} = C_f \frac{S_S}{S_B} \qquad 4.2.3.1\text{-c}$$

where

C_f is the turbulent flat-plate skin-friction coefficient at M = 0.6, including roughness effects, as a function of the Reynolds number based on the reference length ℓ. This value is obtained from figure 4.1.5.1-26 as discussed in paragraph A of Section 4.1.5.1. The reference length ℓ is the actual length of the body ℓ_B. This value is assumed to be constant throughout the transonic region.

$\frac{S_S}{S_B}$ is the ratio of body wetted area to maximum body frontal area, determined as explained in paragraph A of this section.

Step 2. Calculate the subsonic pressure drag at M = 0.6 by

$$C_{D_P} = (C_f)_{M=0.6}\left[\frac{60}{(\ell_B/d)^3} + 0.0025\left(\frac{\ell_B}{d}\right)\right]\frac{S_S}{S_B} \qquad 4.2.3.1\text{-d}$$

where the individual terms are the same as in equation 4.2.3.1-a. This component of drag is assumed to be constant for $0 < M < 1.0$ and to decrease linearly to zero at $M = 1.2$. (See sketch (a).)

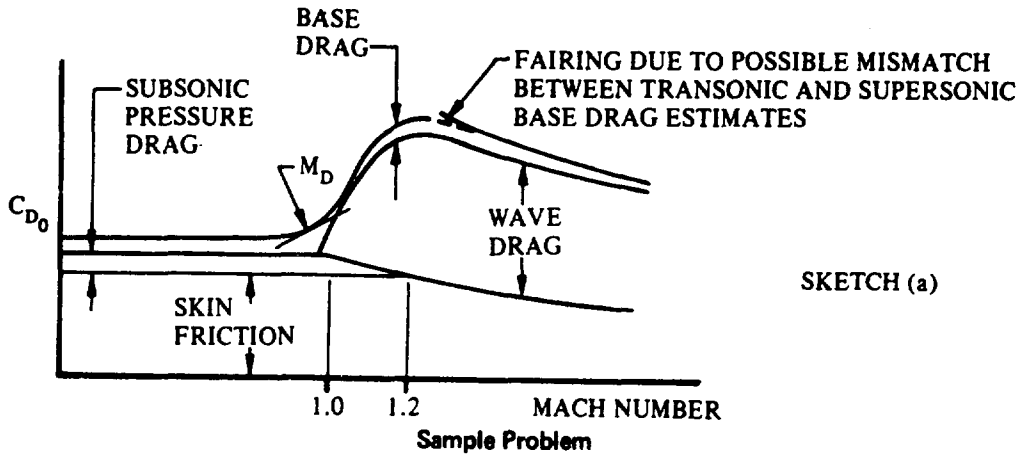
Step 3. Calculate the base-drag coefficient C_{D_b} as a function of Mach number. First calculate the subsonic base drag (at a Mach number of 0.6) as outlined in paragraph A. Figure 4.2.3.1-24 is then used as a guide to determine the base-drag variation with Mach number through the transonic speed range. The chart is based upon the data of references 4 and 9 through 12.

Step 4. The drag-divergence Mach number M_D is obtained from figure 4.2.3.1-25 as a function of body fineness ratio (reference 13). The drag-divergence Mach number is that Mach number at which $\partial C_D / \partial M = 0.10$, and it defines the break in the drag coefficient versus Mach number curve.

Step 5. The wave-drag coefficient C_{D_w} (for parabolic bodies of revolution) is obtained from figure 4.2.3.1-26 as a function of body fineness ratio for Mach numbers between 1.0 and 1.2 (reference 13). Unfortunately, data on other body shapes are extremely limited, and the construction of general charts is not possible at this time. However, for body profiles not too different from parabolic, figure 4.2.3.1-26 can be used as an approximation.

Step 6. The total zero-lift drag is constructed by combining the information of the above steps as illustrated in sketch (a).

$$C_{D_0} = C_{D_f} + C_{D_p} + C_{D_b} + C_{D_w} \qquad \text{4.2.3.1-e}$$



SKETCH (a)

Sample Problem

Given: The parabolic-arc body of revolution with a cutoff afterbody (reference 54).

$\ell_B = 61.45$ in. $\quad d = 6.0$ in. $\quad \ell_B/d = 10.24$ $\quad S_B = 28.2$ sq in.

$S_S/S_B = 30.5$ $\quad d_b/d = 0.50$

$R_{\ell_{M=0.6}} = 1.997 \times 10^7$ (based on ℓ_B)

Polished metal surface; assume $k = 0.08 \times 10^{-3}$ in.

Compute:

The final calculations are presented in table form on page 4.2.3.1-7. Many of the quantities listed below appear as columns in the table.

Skin-friction drag coefficient C_{D_f}

$\ell/k = 61.45/(0.08 \times 10^{-3}) = 7.68 \times 10^5$; cutoff $R_{\ell_{M=0.6}} \approx 6.2 \times 10^7$ (figure 4.1.5.1-27)

Since cutoff R_ℓ > given R_ℓ, read C_f at given R_ℓ.

$C_f = 0.0026$ (figure 4.1.5.1-26 @ M = 0.6)

$$C_{D_f} = C_f \frac{S_S}{S_B} \quad \text{(equation 4.2.3.1-c)}$$

$$= 0.0026\,(30.5) = 0.0793$$

Pressure-drag coefficient C_{D_P}

$$C_{D_P} = (C_f)_{M=0.6} \left[\frac{60}{(\ell_B/d)^3} + 0.0025 \left(\frac{\ell_B}{d} \right) \right] \frac{S_S}{S_B} \quad \text{(equation 4.2.3.1-d)}$$

$$= 0.0026 \left[\frac{60}{(10.24)^3} + 0.0025\,(10.24) \right] 30.5$$

$$= 0.00642$$

This value of C_{D_P} is taken to be constant for $0 < M < 1.0$, then reduced linearly to zero at M = 1.2 (see column (4) of calculation table, page 4.2.3.1-7).

Base-drag coefficient C_{D_b}

$$\left(C_{D_b}\right)_{M=0.8} = 0.029 \left(\frac{d_b}{d} \right)^3 \Big/ \sqrt{\left(C_{D_f}\right)_b} \quad \text{(equation 4.2.3.1-b)}$$

$$\left(C_{D_f}\right)_b = (C_f)_{M=0.6} \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025 \left(\frac{\ell_B}{d} \right) \right] \frac{S_S}{S_B} \quad \text{(first term, eq. 4.2.3.1-a)}$$

$$= (C_f)_{M=0.6} \frac{S_S}{S_B} + C_{D_P}$$

$$= (0.0026)(30.5) + 0.00642 = 0.0857$$

$$C_{D_b} = (0.029)(0.5)^3 / \sqrt{0.0857} = 0.0124$$

$$\left[\frac{C_{D_b}}{\left(\frac{d_b}{d}\right)^2}\right] = \frac{0.0124}{(0.5)^2} = 0.0496$$

With this value and by using the curves of figure 4.2.3.1-24 as guide lines, obtain values of $\frac{C_{D_b}}{(d_b/d)^2}$ for $0.8 < M < 1.2$. Then $C_{D_b} = \left[\frac{C_{D_b}}{(d_b/d)^2}\right] (d_b/d)^2$ (See columns ⑤ and ⑥ of calculation table, page 4.2.3.1-7.)

Drag-Divergence Mach number M_D

$M_D = 0.982$ (figure 4.2.3.1-25)

Wave-drag coefficient C_{D_w}

The wave-drag coefficient as a f(M) is obtained from figure 4.2.3.1-26) (See column ⑦ of calculation table, page 4.2.3.1-7.)

Solution:

$C_{D_0} = C_{D_f} + C_{D_P} + C_{D_b} + C_{D_w}$ (equation 4.2.3.1-e)

① ② ③ ④ ⑤ ⑥ ⑦ ⑧

SKETCH (b)

C. SUPERSONIC

The characteristics of compressible skin-friction drag for bodies are similar to those for wings (see paragraph C of Section 4.1.5.1). The skin-friction coefficient decreases with Mach number at constant Reynolds number, and is a function of the ratio of the wall temperature to the free-stream temperature. For the Datcom, zero heat-transfer conditions are assumed; i.e., stabilized flight conditions are assumed. The friction drag for transient flight lies between the incompressible value and the zero heat-transfer value. Another important consideration for estimating the skin-friction drag at supersonic speeds is the Reynolds-number variation throughout the flight regime. The design chart used in the Datcom method is that of Section 4.1.5.1, which presents the turbulent skin-friction coefficient on an insulated flat plate as a function of Mach number and Reynolds number.

Many theoretical solutions are available for estimating the wave drag of the forebody and afterbody. Reference 14 contains an excellent summary of various theories compared to test data. Ten theories are discussed in this reference. It is seen that second-order shock-expansion theory gives the best over-all agreement with data. Many of the theories are seen to give gross errors over certain ranges of the similarity parameters.

Two methods of estimating the forebody and afterbody wave drag are presented in detail in this section. The first is developed in reference 15 and is based on slender-body theory. The second method is based on similarity parameters and is taken from reference 14. For both methods the wave drag is separated into the

forebody drag, the isolated afterbody drag (afterbody preceded by an infinite cylinder), and the interference drag of the forebody and center (cylindrical) section on the afterbody. Charts are presented for forebody and afterbody drag coefficients of straight-element profiles (cones) and parabolic profiles, and for predicting interference-drag coefficients for conical profiles, pointed parabolic profiles, ducted conical profiles, and truncated afterbodies behind pointed parabolic forebodies. Comprehensive charts based on test data giving the effects of nose bluntness are also presented for the first method.

The first method is applicable to both open-nosed and closed-nosed bodies of revolution. The design charts of the second method for predicting the wave-drag coefficient of the nose are restricted to closed-nosed bodies of revolution. Therefore, the second method is restricted accordingly.

A sizable quantity of data on supersonic base drag exists. Charts derived from test data and theory are presented for a wide range of geometric parameters. For the higher supersonic Mach numbers, theory has been used, and at the lower Mach numbers, empirical results have been used. It should be pointed out that the estimation of the afterbody drag of a body cannot necessarily be accomplished independent of the base. The lambda shock which exists near the end of the body separates the boundary layer over the rear portion of the boattail and thus changes both the base pressure and the pressure loading of the boattail. These effects are included in the base-drag charts presented but are not included in the afterbody charts.

DATCOM METHODS

Method 1. Slender-Body Theory

The zero-lift drag coefficient of open-nosed or closed-nosed bodies of revolution, based on the maximum frontal area, is given by

$$C_{D_0} = C_f \frac{S_S}{S_B} + C_{D_{N_2}} + C_{D_A} + C_{D_{A\,(NC)}} + C_{D_{N_1}} + C_{D_b} \qquad 4.2.3.1\text{-f}$$

where

C_f is the turbulent flat-plate skin-friction coefficient, including roughness effects, as a function of Mach number and the Reynolds number based on the reference length ℓ. This value is obtained from figure 4.1.5.1-26 as discussed in paragraph A of Section 4.1.5.1. The reference length ℓ is the total length of the body ℓ_B.

$\frac{S_S}{S_B}$ is the ratio of body wetted area to maximum body frontal area, determined as outlined in paragraph A of this section.

$C_{D_{N_2}}$ and C_{D_A} are the wave-drag coefficients (reference 15) based on maximum frontal area of the nose and afterbody, respectively. Figure 4.2.3.1-27 is for parabolic profile shapes of circular cross section. Figure 4.2.3.1-28 is for conical profile shapes of circular cross section. A drag value obtained from these charts is the drag acting on the oblique surface and does not include the forces acting on the front or rear faces. The external drag of open-nosed bodies can thus be determined.

The wave-drag coefficients of the nose and afterbody of parabolic and conical profile shapes with noncircular cross sections may be approximated by using a forebody or afterbody of circular cross section and of the same area distribution (equivalent body of revolution). In this case values of a and d to be used in figures 4.2.3.1-27 and 4.2.3.1-28 are the equivalent diameters defined as $\sqrt{\frac{\text{cross-sectional area}}{0.7854}}$.

A more exact estimation of $C_{D_{N_2}}$ and C_{D_A} may be made for parabolic and conical profile shapes with elliptic cross sections by using figure 4.2.3.1-29. This figure presents the decrease in wave-drag coefficient, based on maximum frontal area, from the value for the equivalent body of circular cross section to that for a body of elliptic cross section. The wave-drag coefficient of the equivalent body of circular cross section is first obtained from either figure 4.2.3.1-27 or figure 4.2.3.1-28 by using the equivalent diameters. This value is then reduced by the appropriate value of $\Delta C_{D_{N_2}}$ or ΔC_{D_A} obtained from figure 4.2.3.1-29.

$C_{D_{N_1}}$ is the wave-drag coefficient of spherically blunted noses. The extended fineness ratio of the nose is first determined from figures 4.2.3.1-30 and 4.2.3.1-31 for parabolic and conical noses, respectively. This value is then used to determine the wave drag of the spherical nose segment. Figures 4.2.3.1-32a through 4.2.3.1-32f are for combinations of spherical and parabolic noses. Figures 4.2.3.1-38a through 4.2.3.1-38f are for combinations of spherical and conical noses. These latter charts are based on experimental data of references 17 through 27. When interpolation is necessary, several values should be plotted to provide the correct nonlinear variation. Figures 4.2.3.1-30, -31, -32, and -38 are for noses of circular cross section. For noses with noncircular cross sections $C_{D_{N_1}}$ may be approximated by using a nose of circular cross section and of the same area distribution. In this case the values of the equivalent diameters and the fineness ratios based on the equivalent diameters are used in the design charts.

$C_{D_{A\,(NC)}}$ is the interference-drag coefficient acting on the afterbody due to the centerbody (cylindrical section) and the nose. This coefficient is obtained from figure 4.2.3.1-44 for parabolic profiles, from figure 4.2.3.1-46 for conical profiles, and from figure 4.2.3.1-48 for ducted conical profiles (reference 15). For bodies of noncircular cross section the interference drag coefficient may be approximated by using a body of circular cross section and of the same area distribution. In this case the equivalent diameters are used in the design charts.

C_{D_b} is the base-drag coefficient given by

$$C_{D_b} = -C_{P_b}\left(\frac{d_b}{d}\right)^2 \qquad 4.2.3.1\text{-g}$$

where

C_{P_b} is the base-pressure coefficient from figures 4.2.3.1-50 and 4.2.3.1-55 for ogival and conical boattails of circular cross section, respectively. (Although figure 4.2.3.1-50 is derived for ogive boattails, references 28 through 31, it can be applied to parabolic afterbodies if the ratio d_b/d is not small. Actually, if the ratio is small, the magnitude of the base drag would be such as to minimize the importance of large percentage errors.)

$\frac{d_b}{d}$ is the ratio of the base diameter to the maximum body diameter.

For bodies of noncircular cross section the equivalent diameters should be used in the design charts and in equation 4.2.3.1-g.

For bodies of revolution with no boattail the base-drag coefficient is read directly from figure 4.2.3.1-60.

Method 2. Similarity Parameters

An alternate method based on the correlation of test data by using similarity parameters is presented below. The zero-lift drag coefficient of closed-nosed bodies of revolution, based on the maximum frontal area, is given by

$$C_{D_0} = C_f \frac{S_S}{S_B} + C_{D_{N_2}} + C_{D_A} + C_{D_{A\,(NC)}} + C_{D_{N_1}} + C_{D_b} \qquad 4.2.3.1\text{-h}$$

where C_f, S_S/S_B, $C_{D_{A\,(NC)}}$, $C_{D_{N_1}}$, and C_{D_b} are determined as in method 1, and

$C_{D_{N_2}}$ is the zero-lift wave-drag coefficient of the nose obtained from figure 4.2.3.1-61 or 4.2.3.1-62, which are for ogival- and conical-profile noses of circular cross section, respectively. The K_N factor used in figure 4.2.3.1-61 is given in figure 4.2.3.1-63. The chart for cones is based on references 32 through 37 and the chart for ogive noses is based on references 18, 35, and 38 through 40. Slender-body theory and Newtonian theory have also been used. These charts are discussed and substantiated in reference 14.

C_{D_A} is the zero-lift wave-drag coefficient of the afterbody from figure 4.2.3.1-64 or 4.2.3.1-65, which are for ogival and conical afterbodies with circular cross sections, respectively. These charts are based on Van Dyke's second-order theory and the data of reference 41 and are discussed and substantiated in reference 14.

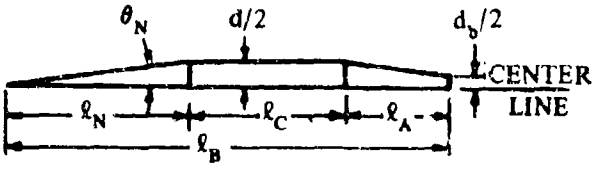
For bodies with noncircular cross sections the component contributions should be based on the equivalent body of circular cross section.

It should be noted that the design charts presented for $C_{D_{N_2}}$ in method 2 are restricted to closed-nosed bodies of revolution.

Sample Problems

1. Method 1. Slender-Body Theory

Given: A cone-cylinder body with the following characteristics (reference 41):



ℓ_B = 129.1 in. $\quad \ell_1 = \ell_N$ = 53.8 in.

$\ell_2 = \ell_C$ = 45.0 in. $\quad \ell_3 = \ell_A$ = 30.3 in.

d = 7.50 in. $\quad d_b$ = 3.28 in.

S_S/S_B = 50.0 $\quad \theta_N = 4^\circ$

Additional characteristics:

M = 1.4; β = 0.980 $\quad R_\ell = 7.6 \times 10^7$ (based on ℓ_B)

Polished metal surface; assume $k = 0.08 \times 10^{-3}$ in.

Compute:

$$\ell/k = \frac{129.1}{0.08 \times 10^{-3}} = 1.61 \times 10^{6}; \text{ cutoff } R_\ell = 2 \times 10^{8} \qquad \text{(figure 4.1.5.1-27)}$$

Since cutoff $R_\ell > 7.6 \times 10^{7}$, read C_f at $R_\ell = 7.6 \times 10^{7}$

$C_f = 0.00192$ (figure 4.1.5.1-26)

Forebody

$$\left(\frac{a_1}{d_1}\right)^2 = 0; \quad \frac{2\ell_1}{\beta d_1} = \frac{2(53.8)}{(0.98)(7.50)} = 14.6$$

$$\left(\frac{2\ell_1}{d_1}\right)^2 = \left[\frac{2(53.8)}{7.50}\right]^2 = 205.8$$

$$C_{D_{N_2}}\left(\frac{2\ell_1}{d_1}\right)^2 = 5.5 \qquad \text{(figure 4.2.3.1-28, extrapolated)}$$

$$C_{D_{N_2}} = (5.5)/(205.8) = 0.0267$$

$C_{D_{N_1}} = 0$ (no bluntness)

Afterbody

$$\left(\frac{a_3}{d_3}\right)^2 = \left(\frac{3.28}{7.50}\right)^2 = 0.191; \quad \frac{2\ell_3}{\beta d_3} = \frac{2(30.3)}{(0.98)(7.50)} = 8.24$$

$$\left(\frac{2\ell_3}{d_3}\right)^2 = \left[\frac{2\,(30.3)}{7.50}\right]^2 = 65.29$$

$$C_{D_A}\left(\frac{2\ell_3}{d_3}\right)^2 = 2.10 \qquad \text{(figure 4.2.3.1-28)}$$

$$C_{D_A} = (2.10)/(65.29) = 0.0322$$

$$\ell_C/\ell_A = \ell_2/\ell_3 = (45)/(30.3) = 1.48$$

$$\ell_N/\ell_A = \ell_1/\ell_3 = (53.8)/(30.3) = 1.78$$

$$C_{D_{A(NC)}}\left(\frac{2\ell_3}{d_3}\right)^2 = 0.27 \quad \text{(figures 4.2.3.1-46b and -46c, interpolated)}$$

$$C_{D_{A(NC)}} = (0.27)/(65.29) = 0.0041$$

$d_b/d = (3.28)/(7.50) = 0.437$; $f_A = \ell_A/d = 30.3/7.50 = 4.04$

$C_{P_b} = -0.055$ (figure 4.2.3.1-55c)

$$C_{D_b} = -C_{P_b}\left(\frac{d_b}{d}\right)^2 \quad \text{(equation 4.2.3.1-g)}$$

$$= -(-0.055)(0.437)^2 = 0.0105$$

Solution:

$$C_{D_0} = C_f\frac{S_S}{S_B} + C_{D_{N_2}} + C_{D_A} + C_{D_{A(NC)}} + C_{D_{N_1}} + C_{D_b} \quad \text{(equation 4.2.3.1-f)}$$

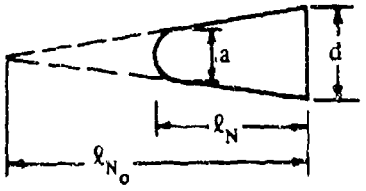
$$= (0.00192)(50.0) + (0.0267) + (0.0322) + (0.0041) + 0 + 0.0105$$

$$= 0.1695 \quad \text{(based on } S_B\text{)}$$

This corresponds to an experimental value of 0.153 from reference 41.

2. Method 1. Slender-Body Theory

Given: The same cone-cylinder body as sample problem 1, except that the nose is spherically blunted.



$\frac{a}{d} = \frac{d_s}{d_o} = 0.60$ $\quad \ell_{N_o} = 53.8$ in.

$d = d_o = 7.50$ in. $\quad \ell_N = 24.0$ in.

$\frac{S_S}{S_B} = 45.8$ $\quad \ell_B = 99.3$ in.

$M = 1.40$; $\beta = 0.98$ $\quad R_{\ell} = 5.85 \times 10^7$ (based on ℓ_B)

Polished metal surface; assume $k = 0.08 \times 10^{-3}$ in.

$C_{D_A} = 0.0322$

$C_{D_{A(NC)}} = 0.0041$

$C_{D_b} = 0.0105$

} Afterbody drag components from sample problem 1

Compute:

$$\ell/k = \frac{99.3}{0.08 \times 10^{-3}} = 1.24 \times 10^{6};\ \text{cutoff } R_\ell \simeq 1.60 \times 10^{8} \qquad \text{(figure 4.1.5.1-27)}$$

Since cutoff $R_\ell > 5.85 \times 10^{7}$, read C_f at $R_\ell = 5.85 \times 10^{7}$

$C_f = 0.0020$ (figure 4.1.5.1-26)

Forebody.

$$\left(\frac{a}{d}\right)^2 = 0.36;\ \frac{2\ell_N}{\beta d} = \frac{2\,(24)}{(0.98)\,(7.50)} = 6.53$$

$$\left(\frac{2\ell_N}{d}\right)^2 = \left[\frac{2(24)}{7.50}\right]^2 = 40.96$$

$$C_{D_{N_2}}\left(\frac{2\ell_N}{d}\right)^2 = 1.16 \qquad \text{(figure 4.2.3.1-28)}$$

$$C_{D_{N_2}} = (1.16)/(40.96) = 0.0283$$

$$f_{N_o} = \ell_{N_o}/d_o = (53.8)/(7.50) = 7.17$$

$C_{D_{N_1}} = 0.200$ (figures 4.2.3.1-38a, -38b, -38c; interpolated)

Solution:

$$C_{D_0} = C_f \frac{S_S}{S_B} + C_{D_{N_2}} + C_{D_A} + C_{D_{A(NC)}} + C_{D_{N_1}} + C_{D_b} \qquad \text{(equation 4.2.3.1-f)}$$

$$= (0.0020)\,(45.8) + 0.0283 + 0.0322 + 0.0041 + 0.200 + 0.0105$$

$$= 0.3667 \quad \text{(based on } S_B\text{)}$$

3. Method 2. Similarity Parameters

Given: The same cone-cylinder body as sample problem 1.

$f_N = 7.17$ $f_A = 4.04$ $d_b/d = 0.437$ $\theta_N = 4^{\circ}$ $M = 1.4;\ \beta = 0.98$

$R_\ell = 7.6 \times 10^{7}$ (based on ℓ_B)

Drag components from sample problem 1:

$$C_f \frac{S_S}{S_B} = 0.0960 \qquad C_{D_{A(NC)}} = 0.0041 \qquad C_{D_{N_1}} = 0 \qquad C_{D_b} = 0.0105$$

Compute:

Forebody

$$\beta/f_N = (0.98)/(7.17) = 0.137$$

$$f_N^2 + \frac{1}{4} = (7.17)^2 + \frac{1}{4} = 51.66$$

$$C_{D_{N_2}} \left[(f_N)^2 + \frac{1}{4}\right] = 1.45 \quad \text{(figure 4.2.3.1-62)}$$

$$C_{D_{N_2}} = (1.45)/(51.66) = 0.0280$$

Afterbody

$$f_A^2 = (4.04)^2 = 16.32; \quad \beta/f_A = (0.98)/(4.04) = 0.243$$

$$C_{D_A} (f_A)^2 = 0.53 \quad \text{(figure 4.2.3.1-65)}$$

$$C_{D_A} = (0.53)/(16.32) = 0.0325$$

Solution:

$$C_{D_0} = C_f \frac{S_S}{S_B} + C_{D_{N_2}} + C_{D_A} + C_{D_{A(NC)}} + C_{D_{N_1}} + C_{D_b} \quad \text{(equation 4.2.3.1-h)}$$

$$= 0.0960 + 0.0280 + 0.0325 + 0.0041 + 0 + 0.0105$$

$$= 0.1711 \quad \text{(based on } S_B\text{)}$$

This corresponds to a calculated value of 0.1695 obtained using method 1, and to an experimental value of 0.153 from reference 41.

D. HYPERSONIC

At hypersonic speeds the zero-lift drag of a body is caused primarily by the pressure and friction drag of the nose. The base drag decreases and becomes insignificant at the higher Mach numbers (see figures 4.2.3.1-50, 4.2.3.1-55, and 4.2.3.1-60).

High-speed turbulent skin-friction values are not well defined at the present time. A theory that has had wide acceptance is that of reference 42. The limited experimental data (e.g., reference 43) substantiate this theory reasonably well.

Figures 4.2.3.1-66 and 4.2.3.1-67 are based upon Newtonian impact values at $M \to \infty$ and should give reasonable results for bodies at these speeds. The charts of reference 44 give the drag of bodies of revolution composed of cone frustums and spherical noses based on Newtonian flow. A similar set of charts is contained in reference 45. A more comprehensive set of charts based on Newtonian flow is available in reference 46 for arbitrary bodies of revolution.

DATCOM METHODS

Method 1. Hypersonic Similarity

The method described as method 2 of paragraph C can be used at hypersonic Mach numbers, but with the body skin-friction drag coefficient calculated as outlined in method 2 that follows (see equation 4.2.3.1-j).

Method 2. Newtonian Flow Plus Skin Friction

The zero-lift drag (based on the maximum frontal area) of bodies composed of cone-cylinder frustums and pointed or spherical noses is estimated by adding the pressure-drag coefficient of each segment to the body skin-friction drag coefficient.

$$C_{D_0} = C_{D_f} + \sum_{n=1}^{m} C_{D_{P_n}} \left(\frac{d_n}{d_{max}}\right)^2 \qquad 4.2.3.1\text{-i}$$

The procedure to be followed in evaluating equation 4.2.3.1-i is:

Step 1 Divide the body into m segments, the first segment being the pointed conical or spherical nose and each succeeding segment a cylinder or circular cone frustum. The pressure-drag coefficient for a spherical nose is obtained from figure 4.2.3.1-66. The pressure-drag coefficient of a pointed conical nose, cylinder, or circular cone frustum is obtained from figure 4.2.3.1-67. (Note that the cylinder is considered as a cone frustum with $\theta = 0$ and $a/d = 1.0$, and that the pressure-drag coefficient is zero by Newtonian impact theory.) Figures 4.2.3.1-66 and 4.2.3.1-67 are from reference 44, and are based on Newtonian impact theory. The pressure-drag coefficients from figures 4.2.3.1-66 and 4.2.3.1-67 are based on the base area of the specific segment. The ratio $(d_n/d_{max})^2$ refers the pressure-drag coefficients to the maximum body frontal area.

Step 2 Obtain the body skin-friction drag coefficient by

$$C_{D_f} = 1.02\, C_{f_{inc}} \frac{C_{f_c}}{C_f} \frac{S_S}{S_B} \qquad 4.2.3.1\text{-j}$$

where

$C_{f_{inc}}$ is the incompressible (M = 0), turbulent, flat-plate skin-friction coefficient, including roughness effects, as a function of Reynolds number based on the total length of the body ℓ_B. This value is obtained from figure 4.1.5.1-26 as discussed in paragraph A of Section 4.1.5.1.

$\frac{C_{f_c}}{C_f}$ is the ratio of compressible to incompressible skin-friction coefficient obtained from figure 4.2.3.1-68.

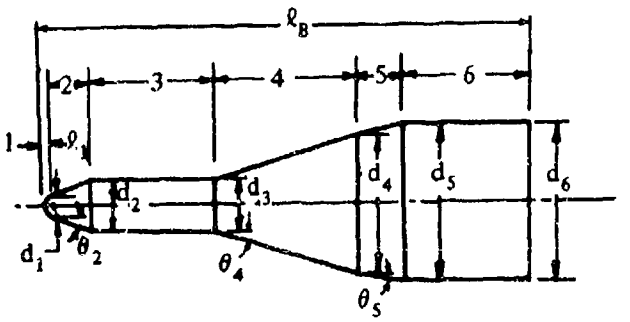
$\frac{S_S}{S_B}$ is the ratio of the body wetted area to maximum body frontal area, determined as outlined in paragraph A of this section.

If method 2 is applied at Mach numbers low enough so that the base drag is significant, the base drag should be added to the results obtained using equation 4.2.3.1-j. Unfortunately, the only base-drag coefficient results available which are compatible with the Newtonian-theory results (restricted to bodies with forward facing slopes or cylinders, in which case the Newtonian results are equal to zero) are those for cylindrical afterbodies. The pressure-drag coefficient for cylindrical afterbodies is presented in figure 4.2.3.1-60 for $M \leq 6$.

Sample Problem

Method 2. Newtonian Flow Plus Skin Friction

Given: A body with the following configuration (reference 54):



Segment 1: Spherical nose

ℓ_1 = 0.29 in. $d_1 = d_s$ = 0.58 in.

Segment 2: Cone frustum

θ_2 = 20° $a_2 = d_1$ = 0.58 in.

d_2 = 1.50 in.

Segment 3: Cylinder

θ_3 = 0 $a_3 = d_2$=1.50 in.

d_3 = 1.50 in.

Segment 4: Cone frustum

θ_4 = 16.5° $a_4 = d_3$ = 1.50 in.

d_4 = 4.10 in.

Segment 5: Cone frustum

θ_5 = 10.4° $a_5 = d_4$ = 4.10 in.

d_5 = 4.50 in.

Segment 6: Cylinder

θ_6 = 0 $a_6 = d_5$ = 4.50 in.

d_6 = 4.50 in.

Additional characteristics:

S_S/S_B = 8.14 ℓ_B = 14.4 in. M = 4.65 R_ℓ = 7.63×10^6 (based on ℓ_B)

Polished metal surface; assume $k = 0.08 \times 10^{-3}$ in.

Compute:

Determine C_{D_p} of the body segments

Segment 1

$\ell_1/(d_1/2) = (0.29)/(0.58/2) = 1.0$

$C_{D_{p_1}} = 1.0$ (figure 4.2.3.1-66)

Segment 2

$a_2/d_2 = (0.58)/(1.50) = 0.387$

$C_{D_{p_2}} = 0.200$ (figure 4.2.3.1-67)

Segment 3

$a_3/d_3 = (1.50)/(1.50) = 1.0$

$C_{D_{p_3}} = 0$ (figure 4.2.3.1-67)

Segment 4

$a_4/d_4 = (1.50)/(4.10) = 0.366$

$C_{D_{p_4}} = 0.138$ (figure 4.2.3.1-67)

Segment 5

$a_5/d_5 = (4.10)/(4.50) = 0.911$

$C_{D_{p_5}} = 0.010$ (figure 4.2.3.1-67)

Segment 6

$a_6/d_6 = (4.50)/(4.50) = 1.0$

$C_{D_{p_6}} = 0$ (figure 4.2.3.1-67)

Determine the skin-friction drag coefficient C_{D_f}

$\ell/k = 14.4/(0.08 \times 10^{-3}) = 0.18 \times 10^6$; cutoff $R_\ell \simeq 7.5 \times 10^7$ (figure 4.1.5.1-27 at M = 0)

Since cutoff $R_\ell > 7.63 \times 10^6$, read C_f at $R_\ell = 7.63 \times 10^6$

$C_f = 0.00314$ (figure 4.1.5.1-26 at M = 0)

$C_{f_c}/C_f = 0.44$ (figure 4.2.3.1-68)

$$C_{D_f} = 1.02\, C_{f_{inc}} \frac{C_{f_c}}{C_f} \frac{S_S}{S_B} \quad \text{(equation 4.2.3.1-j)}$$

$$= (1.02)(0.00314)(0.44)(8.14) = 0.0115$$

Solution:

$$C_{D_0} = C_{D_f} + \sum_{s=n}^{m} C_{D_{p_n}} \left(\frac{d_n}{d_{max}}\right)^2 \quad \text{(equation 4.2.3.1-i)}$$

$$= C_{D_f} + C_{D_{p_1}} \left(\frac{d_1}{d_6}\right)^2 + C_{D_{p_2}} \left(\frac{d_2}{d_6}\right)^2 + C_{D_{p_3}} \left(\frac{d_3}{d_6}\right)^2 + C_{D_{p_4}} \left(\frac{d_4}{d_6}\right)^2 + C_{D_{p_5}} \left(\frac{d_5}{d_6}\right)^2 + C_{D_{p_6}} \left(\frac{d_6}{d_6}\right)^2$$

$$= 0.0115 + (1.0)\left(\frac{0.58}{4.50}\right)^2 + (0.200)\left(\frac{1.50}{4.50}\right)^2 + 0 + (0.138)\left(\frac{4.10}{4.50}\right)^2 + (0.010)\left(\frac{4.50}{4.50}\right)^2 + 0$$

$$= 0.175 \quad \text{(based on } S_B\text{)}$$

The Mach number of this example is low enough so that the base drag is significant. The base drag coefficient is obtained from figure 4.2.3.1-60 as

$C_{D_b} = 0.055$ (based on S_B)

So, the final result is

$C_{D_0} = C_{D_f} + C_{D_p} + C_{D_b} = 2.30$ (based on S_B)

This result compares favorably with the test value shown in reference 54.

E. RAREFIED GAS

In the discussions of aerodynamic properties presented previously, it has been assumed that the air behaves as a continuous fluid; whereas, at the very low densities encountered at extreme altitudes the actual molecular structure of the air will become important.

By accepted definition (reference 47) a rarefied gas flow is a flow in which the length of the molecular mean free path is comparable to some significant dimension of the flow field. The ratio of these two lengths is called the Knudsen number. If the characteristic length is chosen to be the body dimension used in the definition of Reynolds number, then the Knudsen number can be shown to be given approximately by

$$Kn \approx M/R_{\ell}$$

By the definition given above, the flow can be considered as rarefied if $Kn > 1$. If the flow is very rarefied, say $Kn > 3$ (reference 47) then individual gas molecules strike the surface of the body without interacting with surrounding gas molecules; this flow regime is called free-molecule flow. Between the regime of free-molecule flow and that of continuous gas dynamics (where $Kn \approx 10^{-4}$ or 10^{-5}) lies a large transition region that is not yet clearly defined as to its characteristics.

It is apparent that, if $Kn = 3$ defines the limit for the free-molecule flow regime, the aerodynamics of bodies in this type of flow is of interest only in its application to satellite studies. A Knudsen number of three corresponds to an altitude of roughly 100 miles, if the reference length used is only one foot, with increasing altitude for larger reference dimensions. It seems unlikely that anything resembling a full-size aircraft will attempt to utilize the tenuous atmosphere at these extreme altitudes for a useful purpose without flying at essentially orbital speeds. It is not possible to make any clearcut statements regarding the transition regime. The region likely to be of most interest in aircraft and missile work is that where the flow is just slightly rarefied, that is, where the continuous flow equations are just beginning to become questionable. This is called the slip-flow regime. In the slip-flow regime either the Mach number is large or the Reynolds number is small, by continuum standards. Analysis of the slip-flow regime is difficult, because its characteristics are likely to be masked by compressibility and viscosity effects.

An excellent discussion is presented by Hayes and Probstein (reference 48) concerning the validity of continuum theory as applied to rarefied gas flow. It is concluded that, when properly applied, continuum gas dynamics and viscous flow theory can be useful far into the regime of what is normally considered the domain of kinetic theory.

At the other end of the spectrum, free-molecule flow theory is important for several problems dealing with satellites. Since satellites generally operate in the free-molecule flow regime, it is necessary to estimate the drag coefficient under these conditions in order to predict the perturbations and decay of the orbit, and to use satellite measurements to estimate atmospheric density.

There are many analyses in the literature on the lift and drag of bodies in free-molecule flow (references 47, 49, 50, and 51), since the problem is amenable to analytical solution. In the discussion of reference 47, expressions for the local pressure and shear forces are given in general form, so that these forces can be computed for any type of interaction of the atmospheric molecules with the body surface. At the present, very little is known of the nature of this interaction, and more research is required to establish the type of interaction that may be expected in a specific problem.

Jastrow and Pearse (reference 52) have discussed an additional drag that arises in the flight of a body through a medium containing ions and electrons, as in the ionosphere. The satellite tends to acquire a negative equilibrium electrostatic potential. As a result, atmospheric ions that would otherwise have missed the satellite are drawn into collisions with it, thus increasing the drag.

Integrated drag forces for the simple shapes of the cylinder and sphere are given in reference 47. These data are shown in figure 4.2.3.1-69 for the simplified case in which the surface temperature is equal to the ambient temperature, and for the extremes of specular and fully diffuse reflection.

4.2.3.2 BODY DRAG AT ANGLE OF ATTACK

The drag of bodies at angle of attack is closely related to their lift and drag at zero angle of attack. The total drag of a body at angle of attack can be expressed as

$$C_D = C_{D_0} + C_D(\alpha) \qquad 4.2.3.2\text{-a}$$

where C_{D_0} is the body zero-lift drag, as developed in Section 4.2.3.1, and $C_D(\alpha)$ is the drag due to angle of attack as determined in this section. Discussions of the various applicable theories are given in Sections 4.2.1.1 and 4.2.1.2 and will not be repeated here.

A. SUBSONIC

Four methods are presented for estimating body drag due to angle of attack. The first method is taken from Reference 1 and is quite general since it applies to both short and long bodies of revolution. This method assumes that the flow is potential over the forward part of the body and has no viscous contribution in this region. On the aft part of the body, the flow is assumed to be entirely viscous, with lift arising solely from cross-flow drag. The second method, taken from Reference 2, is accurate to within ±10 percent for bodies of high fineness ratio but is not accurate for bodies of low fineness ratio. This method assumes that the viscous contribution at each station along the body is equal to the steady-state drag of a section of an infinite cylinder placed normal to a flow with velocity V sin α. This method is included for bodies of high fineness ratio because of its ease of application. The third method, taken from Reference 3, is also given because of its ease of application. This method is limited in application to small angles of attack and moderate fineness ratios. The fourth method, taken from Reference 4, presents a method of computing axial-force coefficient. This method (based on slender-body theory) applies to the angle-of-attack range of 0 to 180° for bodies with circular cross sections. It is recommended that one of the first three methods be used in the low-angle-of-attack range.

DATCOM METHODS

Method 1. General

The subsonic drag due to angle of attack of a body of revolution, based on $(V_B)^{2/3}$, is given in Reference 1 as

$$C_D(\alpha) = \frac{(k_2 - k_1)}{(V_B)^{2/3}} 2\alpha^2 S_o + \frac{2\alpha^3}{(V_B)^{2/3}} \int_{x_o}^{\ell_B} \eta\, r\, c_{d_c}\, dx \qquad 4.2.3.2\text{-b}$$

where

$\frac{(k_2 - k_1)}{(V_B)^{2/3}} 2\alpha^2 S_o$ is the potential-flow solution for C_{L_α} from Paragraph A of Section 4.2.1.1, multiplied by α^2

$\frac{2\alpha^3}{(V_B)^{2/3}} \int_{x_o}^{\ell_B} \eta\, r\, c_{d_c}\, dx$ is the viscous solution for C_L at angle of attack from Paragraph A of Section 4.2.1.2, multiplied by α.

α is the body angle of attack in radians.

All the parameters required to solve Equation 4.2.3.2-b are defined in Sections 4.2.1.1 and 4.2.1.2.

Method 2. Bodies of High Fineness Ratio

The subsonic drag due to angle of attack of a body of revolution, based on $(V_B)^{2/3}$, is given in Reference 2 as

$$C_D(\alpha) = 2\alpha^2 \frac{S_b}{(V_B)^{2/3}} + \eta c_{d_c} \frac{S_p}{(V_B)^{2/3}} \alpha^3 \qquad 4.2.3.2\text{-c}$$

where

S_b is the body base area.

V_B is the total body volume.

S_p is the body planform area.

α is the body angle of attack in radians.

η is the ratio of the drag on a finite cylinder to the drag on an infinite cylinder, obtained from Figure 4.2.1.2-35a as a function of the body fineness ratio ℓ_B/d.

c_{d_c} is the experimental steady-state cross-flow drag coefficient of a circular cylinder of infinite length, obtained from Figure 4.2.1.2-35b as a function of the cross-flow Mach number at a given angle of attack.

Comparisons between results obtained by this method and test results (Reference 2) show that the body drag due to angle of attack is, in general, fairly accurately predicted up to moderate angles of attack for bodies with fineness ratios as low as about 6. For bodies with fineness ratios of about 15 and greater, the method should predict the drag due to angle of attack quite accurately over the angle-of-attack range of practical interest.

Method 3. $\alpha < 10^o$ and $2f \tan\alpha < 5$

For the range of parameters $\alpha < 10^o$ and $2f \tan\alpha < 5$, the simplified method of Reference 3 indicates that the subsonic drag due to angle of attack of a body of revolution, based on body base area, may be given as

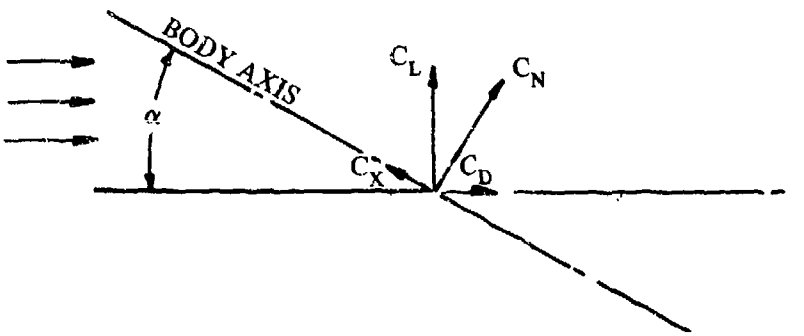
$$C_D(\alpha) = \alpha^2 + 0.49 f^2 \frac{c_{d_c}}{S_b} \alpha^4 \qquad 4.2.3.2\text{-d}$$

where α is the body angle of attack in radians, f is the body fineness ratio, and the remaining parameters are defined in Method 2 above.

The first three sample problems illustrate the accuracy of the above methods applied to the same configuration.

Method 4. High Angles of Attack

The method of Reference 4 is applicable to the angle-of-attack range of 0 to 180°. Due to the complexity of calculating drag for bodies with noncircular cross sections, the Datcom method is limited to bodies with circular cross sections. For noncircular cross-section bodies, the user is referred to the treatment presented in References 4 and 5. The Datcom method predicts axial-force coefficient C_X based on body base area. Sketch (a) shows how this term may be used in conjunction with the C_N calculated in Section 4.2.1.2 to obtain C_D ($C_D = C_N \sin\alpha - C_X \cos\alpha$).



SKETCH (a)

The axial force C_X of a circular-cross-section body at an angle of attack, based on the body base area, is given by

$$C_X = C_{X_{\alpha=0}} \cos^2\alpha' \quad (\text{for } 0 \leqslant \alpha \leqslant 90^\circ) \qquad 4.2.3.2\text{-e}$$

$$C_X = C_{X_{\alpha=180^\circ}} \cos^2\alpha' \quad (\text{for } 90^\circ \leqslant \alpha \leqslant 180^\circ \qquad 4.2.3.2\text{-f}$$

and

$$C_{X_{\alpha=0}} = -(C_f + C_{D_b}) \qquad 4.2.3.2\text{-g}$$

$$C_{X_{\alpha=180^\circ}} = C_f + C_{D_b} \qquad 4.2.3.2\text{-h}$$

where

$C_{X_{\alpha=0}}$ is the axial-force coefficient at $\alpha = 0$.

α' is an incidence angle defined as $\alpha' = \alpha$ for $0 \leq \alpha \leq 90^{\circ}$ and $\alpha' = 180^{\circ} - \alpha$ for $90^{\circ} < \alpha < 180^{\circ}$.

$C_{X_{\alpha=180^{\circ}}}$ is the axial-force coefficient at $\alpha = 180^{\circ}$.

C_f is the turbulent flat-plate skin-friction coefficient based on the reference length. This value is obtained from Figure 4.2.3.2-27 as a function of Reynolds number (based on body length) and Mach number.

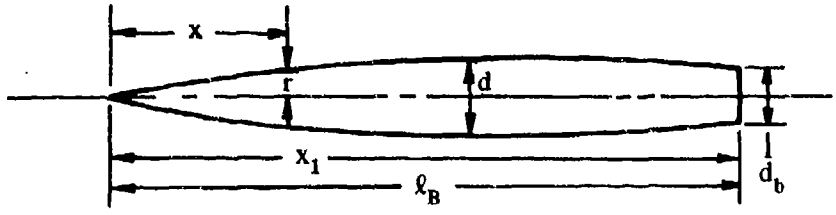
C_{D_b} is the base-drag coefficient based on the maximum body frontal area, given by Equation 4.2.3.1-b.

It is recommended that this method be used only in the high-angle-of-attack range where other Datcom methods are not applicable. No substantiating test data are available for this method in the subsonic speed range.

Sample Problems

1. Method 1

Given: The parabolic body of revolution of Reference 10.



$\ell_B = 5.04$ ft d = 0.510 ft $d_b = 0.376$ ft f = 9.87

$V_B = 0.687$ cu ft; $(V_B)^{2/3} = 0.7786$ sq ft M = 0.40 $0 \leq \alpha \leq 18^{\circ}$

Body ordinates: $r = 0.255\left[1 - \left(1 - \frac{2x}{6.375}\right)^2\right]^{1/4}$

Compute:

Potential Flow Term (Section 4.2.1.1)

$x_1 = 5.04$ ft*

$x_1/\ell_B = 5.04/5.04 = 1.0$

* x_1 may be determined by inspection for this case

$x_o/\ell_B = 0.903$ (Figure 4.2.1.1-20b)

$x_o = (0.903)(5.04) = 4.55$ ft

$$S_o = \pi(r_o)^2 = \pi\left\{0.255\left[1-\left(1-\frac{2x_o}{6.375}\right)^2\right]^{3/4}\right\}^2 = \pi\left\{0.255\left[1-\left(1-\frac{(2)(4.55)}{6.375}\right)^2\right]^{3/4}\right\}^2$$

$= 0.151$ sq ft

$(k_2 - k_1) = 0.938$ (Figure 4.2.1.1-20a)

$$\frac{(k_2-k_1)}{(V_B)^{2/3}}\,2\alpha^2 S_o = \frac{(0.938)}{(0.7786)}\,2\alpha^2\,(0.151) = 0.364\,\alpha^2$$

Viscous Term (Section 4.2.1.2)

$\eta = 0.685$ (Figure 4.2.1.2-35a)

$c_{d_c} = f(M_c)$; $M_c = M \sin\alpha$

M_c varies between 0.40 sin (0) to 0.40 sin 18^o; $0 \le M_c \le 0.1236$

$c_{d_c} = 1.20$ (constant) (Figure 4.2.1.2-35b)

$$\int_{x_o}^{\ell_B} \eta\, r\, c_{d_c}\, dx = (0.685)(1.20)\int_{x_o}^{\ell_B} r\, dx = 0.822 \sum_{x_o}^{\ell_B} r\,\Delta x$$

x	r*	Δx	rΔx
$x_o = 4.55$	0.2136	0.20	0.043
4.75	0.2010	0.20	0.040
4.95	0.1906	0.09	0.017
$\ell_B = 5.04$			

$\Sigma r\Delta x = 0.100$

$$\int_{x_o}^{\ell_B} \eta\, r\, c_{d_c}\, dx = (0.822)(0.100) = 0.0822$$

* r is taken to be at the midpoint of each body segment.

$$\frac{2\alpha^3}{(V_B)^{2/3}} \int_{X_o}^{\ell_B} \eta \, r \, c_{d_c} \, dx = \frac{2\alpha^3}{(0.7786)} (0.0822) = 0.211 \, \alpha^3$$

Solution:

$$C_D(\alpha) = \frac{(k_2 - k_1)}{(V_B)^{2/3}} 2\alpha^2 S_o + \frac{2\alpha^3}{(V_B)^{2/3}} \int_{X_o}^{\ell_B} \eta \, r \, c_{d_c} \, dx \quad \text{(Equation 4.2.3.2-b)}$$

$$= 0.364 \, \alpha^2 + 0.211 \, \alpha^3$$

The calculated results are compared with test values from Reference 10 in Sketch (b).

2. Method 2

Given: The same configuration as in Sample Problem 1.

Additional Characteristics:

$S_b = 0.111$ sq ft $\quad S_p = 2.016$ sq ft

Compute:

Potential Flow Term

$$2\alpha^2 \frac{S_b}{(V_B)^{2/3}} = 2\alpha^2 \left(\frac{0.111}{0.7786}\right) = 0.285 \, \alpha^2$$

Viscous Term

$$\left.\begin{aligned}\eta &= 0.685\\ c_{d_c} &= 1.20\end{aligned}\right\}\ \text{(Sample Problem 1)}$$

$$\eta\, c_{d_c} \frac{S_p}{(V_B)^{2/3}} \alpha^3 = (0.685)(1.20)\frac{2.016}{0.7786}\alpha^3 = 2.128\,\alpha^3$$

Solution:

$$C_D(\alpha) = 2\alpha^2 \frac{S_b}{(V_B)^{2/3}} + \eta\, c_{d_c} \frac{S_p}{(V_B)^{2/3}} \alpha^3 \quad \text{(Equation 4.2.3.2-c)}$$

$$= 0.285\,\alpha^2 + 2.128\,\alpha^3$$

SKETCH (b)

4. Method 4

Given: The same configuration as in Sample Problems 1, 2, and 3.

Additional Characteristics:

$\alpha = 50^{o}$ $\qquad R_{\ell} = 10^{6}$

Compute:

$\alpha' = \alpha = 50^{o}$

$C_f = 0.0042$ (Figure 4.2.3.2-27)

$\ell_B/d = \dfrac{5.04}{0.510} = 9.88$ $\qquad \dfrac{d_b}{d} = \dfrac{0.376}{0.510} = 0.737$ (Sample Problem 1)

$\dfrac{S_S}{S_b} = 28.7$ (Figure 2.3-3)

$$(C_{D_f})_b = C_f \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\left(\frac{\ell_B}{d}\right)\right] \frac{S_S}{S_B}$$ (first term in Equation 4.2.3.1-a)

$$= 0.0042 \left[1 + \frac{60}{(5.04/0.510)^3} + 0.0025\left(\frac{5.04}{0.510}\right)\right] 28.7$$

$$= 0.131$$

$$C_{D_b} = 0.029 \left(\frac{d_b}{d}\right)^3 \Big/ \sqrt{(C_{D_f})_b}$$ (Equation 4.2.3.1-b

$$= (0.029)\left(\frac{0.376}{0.510}\right)^3 \Big/ \sqrt{0.131}$$

$$= 0.0321$$

Solution:

$$C_{X_{\alpha=0}} = -(C_f + C_{D_b})$$ (Equation 4.2.3.2-g)

$$= -(0.0042 + 0.0321)$$

$$= -0.0363$$

$$C_X = C_{X_{\alpha=0}} \cos^2\alpha' \quad \text{(Equation 4.2.3.2-e)}$$

$$= -(0.0363)(0.6428)^2$$

$$= -0.0150 \text{ (based on body base area)}$$

No test data are available for a comparison.

B. TRANSONIC

Slender-body theory may be applied for a rapid but approximate estimate of body drag at angle of attack.

DATCOM METHOD

The drag coefficient due to angle of attack from slender-body theory is

$$C_D(\alpha) = \alpha^2 \text{ (based on } S_b) \qquad 4.2.3.2\text{-i}$$

where the drag coefficient is referred to body base area and α is the body angle of attack in radians.

C. SUPERSONIC

Three methods are given for estimating body drag due to angle of attack at supersonic speeds. The first two methods correspond to the first two methods of estimating body lift in Section 4.2.1.2. The general discussion of the methods used in Section 4.2.1.2 will not be repeated here. In addition, a third method is given for estimating the body axial-force coefficient (based on Reference 4 and similar to Method 4 of Paragraph A of this section). This method is applicable up to an angle of attack of 180° and is limited to bodies of revolution with blunt, conical, ogive, and 3/4-power noses.

DATCOM METHODS

Method 1

The supersonic body drag due to angle of attack, determined by the method of Reference 9 for moderate angles of attack, is

$$C_D(\alpha) = C_L\alpha \qquad 4.2.3.2\text{-j}$$

where C_L is given by Equation 4.2.1.2-g or Equation 4.2.1.2-h, depending on whether the body cross section is circular or elliptical, and α is the angle of attack in radians.

The supersonic drag due to angle of attack of a body of revolution, based on body base area, is then

$$C_D(\alpha) = 2\alpha^2 + c_{d_c}\frac{S_p}{S_b}\alpha^3 \qquad 4.2.3.2\text{-k}$$

where all the parameters are defined under Method 2 of Paragraph A.

The supersonic drag due to angle of attack of a body having an elliptical cross section, based on body base area, is

$$[C_D(\alpha)]_{a/b} = \left[\frac{a}{b}\cos^2\phi + \frac{b}{a}\sin^2\phi\right] C_D(\alpha) \qquad 4.2.3.2\text{-}l$$

where

a is the major axis of the elliptical cross section.

b is the minor axis of the elliptical cross section.

ϕ is the angle of bank of the body about its longitudinal axis; $\phi = 0$ with the major axis horizontal and $\phi = 90^o$ with the minor axis horizontal.

$C_D(\alpha)$ is the drag due to angle of attack of a body of revolution having the the same cross-sectional area distribution along its axis as the elliptical-cross-section body of interest. It is given by Equation 4.2.3.2-k.

Calculated results using this method have been compared with test data in Reference 9. The comparison included bodies of revolution and bodies of elliptical cross section, both having the same axial distribution of cross-sectional area. The tests included bodies of fineness ratios 6 and 10 at M = 1.98 and bodies of fineness ratio 6 at M = 3.88. The angle-of-attack range was from zero to approximately 20^o. For the cases considered, there is good agreement between results calculated by this method and test values.

Method 2

A method for predicting the normal force of bodies of revolution at supersonic speeds is given in Section 4.2.1.2. The drag due to angle of attack of a body of revolution can be expressed as

$$C_D(\alpha) = C_N \sin\alpha - C_X \cos\alpha \qquad 4.2.3.2\text{-m}$$

where C_N and C_X are defined in Sketch (a). For small angles of attack the resultant force vector is nearly normal to the body surface and the chordwise force component is neglected. Equation 4.2.3.2-m can then be approximated at small angles of attack as

$$C_D(\alpha) = C_N\alpha \qquad 4.2.3.2\text{-n}$$

where

α is the body angle of attack in radians.

C_N is the body normal-force coefficient at angle of attack, based on body base area, obtained from Figure 4.2.1.2-38.

The normal-force data of Figure 4.2.1.2-38 are for cone-cylinder configurations, but may be used for general pointed bodies without great loss of accuracy.

Method 3

The following method (Reference 4) predicts the axial-force coefficient C_X in the angle-of-attack range of 0 to 180°. The method is limited to bodies of revolution with blunt, conical, ogive, and 3/4-power nose shapes. Due to the complexity of calculating drag for bodies with noncircular cross sections, the Datcom method is limited to bodies with circular cross sections. For noncircular cross-section bodies, the user is referred to the treatment presented in References 4 and 5. This C_X term may be used in conjunction with the C_N calculated in Section 4.2.1.2 to obtain C_D; i.e., $C_D = C_N \sin\alpha - C_X \cos\alpha$.

The axial-force C_X of a circular-cross-section body at an angle of attack is given by

$$C_X = C_{X_{\alpha=0}} \cos^2\alpha' \quad (\text{for } 0 \leqslant \alpha \leqslant 90^\circ) \qquad 4.2.3.2\text{-o}$$

$$C_X = C_{X_{\alpha=180^\circ}} \cos^2\alpha' \quad (\text{for } 90^\circ \leqslant \alpha \leqslant 180^\circ) \qquad 4.2.3.2\text{-p}$$

and

$$C_{X_{\alpha=0}} = -(C_f + C_{D_b} + C_{D_w}) \qquad 4.2.3.2\text{-q}$$

$$C_{X_{\alpha=180^\circ}} = C_f + C_{D_b} + C_{D_w} \qquad 4.2.3.2\text{-r}$$

where

C_{D_b} is the base-drag coefficient for bodies of revolution, from Figure 4.2.3.1-60.

C_{D_w} is the wave-drag coefficient determined from Figure 4.2.3.2-28a for blunt nose or blunt base forward, or Figure 4.2.3.2-28b for other nose shapes.

The remaining terms are defined in Paragraph A of Section 4.2.3.2.

A comparison of test data taken from References 7 and 8 with results calculated by this method is presented in Table 4.2.3.2-A. It should be noted that very little reliable test data at high angles of attack were available, and much of that used to substantiate the method is suspected of being affected by model support interference. The method generally predicts a lower absolute value of C_X than evidenced by available test data; however, the user should be cautious in view of the uncertainty of the test data.

It is recommended that other Datcom methods be used whenever possible, especially at low angles of attack.

The method is applicable to $0 \leqslant M \leqslant 7$; however, caution should be used in the hypersonic range because of the lack of substantiating data.

Sample Problems

1. Method 1

Given: Three bodies of Reference 11, each having the same longitudinal area distribution.

Body 1. Ogive-cylinder

ℓ_B = 42.0 in. ℓ_N = 14.0 in. ℓ_A = 28.0 in. $d_b = d_{max}$ = 4.0 in.

f = 10.5 S_b = 12.57 sq in. S_p = 154.0 sq in.

Body 2. Horizontal ellipse

Same longitudinal area distribution as ogive-cylinder body.

a = 4.90 in. b = 3.26 in. $\phi = 0$

Body 3. Vertical ellipse

Same longitudinal area distribution as ogive-cylinder body.

a = 4.90 in. b = 3.26 in. $\phi = 90^o$

Additional Characteristics:

M = 2.01; β = 1.744 $0 \leq \alpha \leq 10^o$

Body 1. Ogive-cylinder

Compute:

S_p/S_b = 154.0/12.57 = 12.25

M_c = M sin α

c_{d_c} (Figure 4.2.1.2-35b)

} (See calculation table below.)

Solution:

$$C_D(\alpha) = 2\alpha^2 + c_{d_c} \frac{S_p}{S_b} \alpha^3$$ (Equation 4.2.3.2-k)

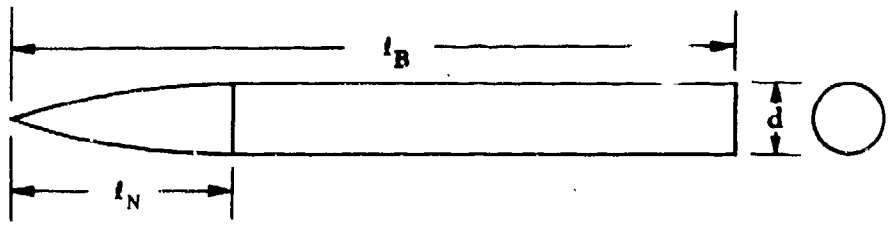
SKETCH (c)

3. Method 3

Given: An ogive-cylinder body of Reference 7.



Body Characteristics:

$$\frac{\ell_B}{d} = 11 \qquad \frac{\ell_N}{d} = 5$$

Additional Characteristics:

$$\alpha = 40^o, 120^o \qquad M = 2.86 \qquad R_\ell = 1.375 \times 10^6$$

Compute:

C_X at $\alpha = 40^o$

$$\alpha' = \alpha = 40^o$$

$$C_f = 0.00287 \text{ (Figure 4.2.3.2-27)}$$

$$C_{D_b} = 0.103 \text{ (Figure 4.2.3.1-60)}$$

$$M\frac{d}{\ell_N} = (2.86)\left(\frac{1}{5}\right) = 0.572$$

$$0.7M^2 C_{D_w} = 0.215 \text{ (Figure 4.2.3.2-28b)}$$

$$C_{D_w} = \frac{0.215}{0.7M^2} = \frac{0.215}{0.7(2.86)^2} = 0.0375$$

$$C_{X_{\alpha=0}} = -(C_f + C_{D_b} + C_{D_w}) \text{ (Equation 4.2.3.2-q)}$$

$$= -(0.00287 + 0.103 + 0.0375)$$

$$= -0.143$$

$$C_X = C_{X_{\alpha=0}} \cos^2\alpha' \quad \text{(Equation 4.2.3.2-o)}$$

$$= -(0.143)(0.587)$$

$$= -0.084 \text{ (based on body base area)}$$

C_X at $\alpha = 120^o$

$$\alpha' = 180^o - \alpha = 60^o$$

$C_f = 0.00287$ (Figure 4.2.3.2-27)

$C_{D_b} = 0.103$ (Figure 4.2.3.1-60)

$C_{D_w} = 1.747$ (Figure 4.2.3.2-28a for blunt base forward)

$$C_{X_{\alpha=180^o}} = C_f + C_{D_b} + C_{D_w} \quad \text{(Equation 4.2.3.2-r)}$$

$$= 0.00287 + 0.103 + 1.747$$

$$= 1.85$$

$$C_X = C_{X_{\alpha=180^o}} \cos^2\alpha' \quad \text{(Equation 4.2.3.2-p)}$$

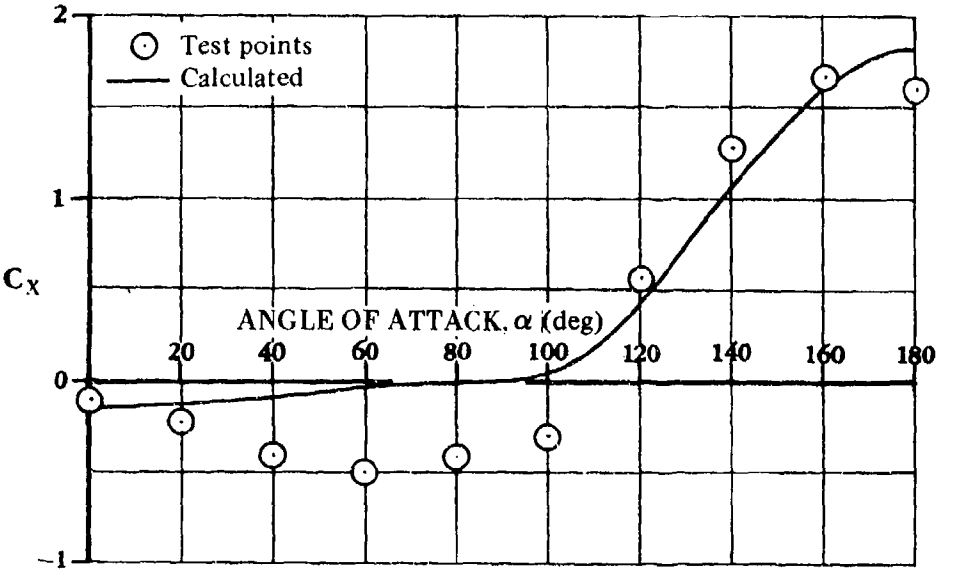
$$= (1.85)(0.25)$$

$$= 0.46 \text{ (based on body base area)}$$

Additional values have been calculated below:

M	α (deg)	C_X
2.86	0	−0.14
2.86	20	−0.126
2.86	40	−0.084
2.86	60	−0.036
2.86	80	−0.004
2.86	100	0.006
2.86	120	0.46
2.86	140	1.08
2.86	160	1.63
2.86	180	1.84

The calculated results of the sample problem are compared to test values from Reference 7 in Sketch (d).



SKETCH (d)

D. HYPERSONIC

For small or moderate angles of attack the hypersonic drag of a body is given by Method 2 of Paragraph C. For large angles of attack the method of Reference 4 presented as Method 3 of Paragraph C of this section may be used.

DATCOM METHODS

Method 1

At small to moderate angles of attack, body drag due to angle of attack, based on base area, is given by Equation 4.2.3.2-n; i.e.,

$$C_D(\alpha) = C_N \alpha$$

where C_N is obtained from Paragraph D of Section 4.2.1.2 and α is the body angle of attack in radians. The design charts of Section 4.2.1.2 can be used to determine the normal-force coefficient at angles of attack for cone-cylinder-flare, cone-cylinder, or cone-flare bodies with pointed or spherically blunted noses, or for spherically blunted or pointed cones.

An approximate value of $C_D(\alpha)$ at small angles of attack for a spherically blunted ogive can be determined by

$$C_D(\alpha) = C_{N_\alpha} \alpha^2 \qquad 4.2.3.2\text{-s}$$

where C_{N_α} is obtained from Figure 4.2.1.1-25 and α is the body angle of attack in radians.

Method 2

This method is identical to Method 3 presented in Paragraph C of this section. The method is applicable to angles of attack from 0 to 180° and Mach numbers up to 7. Substantiating test data taken from Reference 8 for $\alpha \leq 25^{\circ}$ are presented in Table 4.2.3.2-A. The method has not been substantiated at higher angles of attack. It is recommended that the method be used cautiously and only when Method 1 cannot be used.

Sample Problems

1. Method 1

Given: A cone-cylinder body of Reference 12.

ℓ_B = 8.0 in. ℓ_A = 4.68 in. ℓ_N = 3.32 in. d = 1.17 in.

M = 6.86; β = 6.79 $0 \leq \alpha \leq 24^{\circ}$

Compute:

$$f_A = \frac{\ell_A}{d} = \frac{4.68}{1.17} = 4.0; \quad f_N = \frac{\ell_N}{d} = \frac{3.32}{1.17} = 2.84$$

f_A/f_N = 4.0/2.84 = 1.41

β/f_N = 6.79/2.84 = 2.39

βC_N (Figure 4.2.1.2-40a through -40d, interpolated) (See calculation table.)

C_N = $\beta C_N/\beta$ (based on body base area) (See calculation table.)

Solution:

$C_D(\alpha) = C_N \alpha$ (based on S_b) (Equation 4.2.3.2-n)

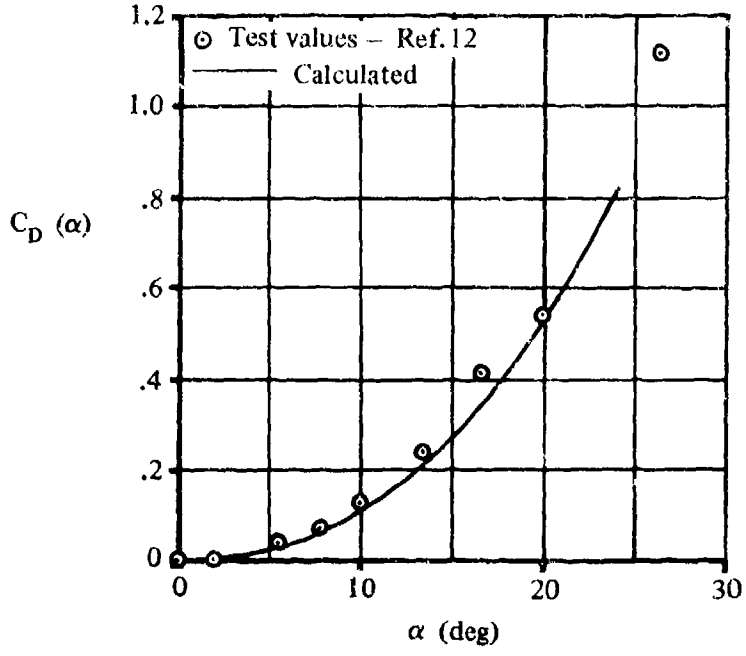
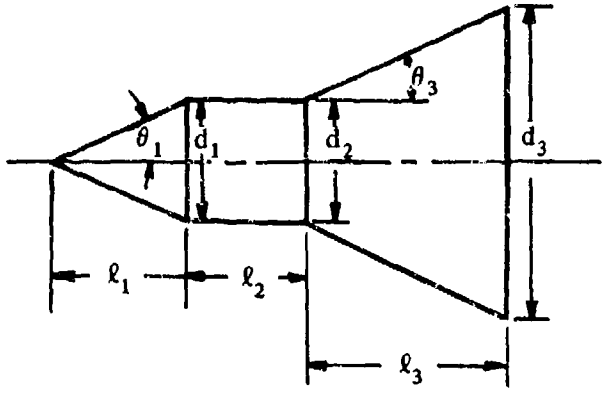
The calculated results are compared with test values from Reference 12 in Sketch (e)



SKETCH (e)

2. Method 1

Given: A cone-cylinder-flare body of Reference 13.



Cone:

$\ell_1 = \ell_N = 2.414$ in.

$d_1 = d_2 = 2.0$ in. $\theta_1 = 22.5^o$

Cylinder:

$\ell_2 = \ell_C = 2.0$ in. $d_2 = 2.0$ in.

Flare:

$\ell_3 = \ell_F = 3.29$ in.

$d_3 = 5.80$ in. $\theta_3 = 30^o$

Additional Characteristics:

$M = 6.0$; $\beta = 5.92$ $0 \leq \alpha \leq 16^o$

Compute:

In accordance with the method of Section 4.2.1.2, the increment of normal force due to the flare is added to the normal force of the cone-cylinder body.

$(C_N)_{cone\text{-}cylinder}$

$f_N = \ell_N/d = 2.414/2.0 = 1.207$

$f_A = f_C = \ell_C/d = 2.0/2.0 = 1.0$

$f_A/f_N = 1.0/1.207 = 0.829$

$\beta/f_N = 5.92/1.207 = 4.90$

βC_N (Figure 4.2.1.2-40d and -40e, interpolated) (See calculation table.)

$C_N = \beta C_N/\beta$ (based on cone-cylinder maximum frontal area) (See calculation table.)

$(C_N)_{flare}$

$$1 - \left(\frac{d_2}{d_3}\right)^2 = 1 - \left(\frac{2.0}{5.80}\right)^2 = 1 - 0.119 = 0.881$$

$$\frac{(\Delta C_N)_F}{1 - \left(\frac{d_2}{d_3}\right)^2}$$ (Figure 4.2.1.2-42b) (See calculation table.)

$$(\Delta C_N)_F = \frac{(\Delta C_N)_F}{1 - \left(\frac{d_2}{d_3}\right)^2}\left[1 - \left(\frac{d_2}{d_3}\right)^2\right] = 0.881 \frac{(\Delta C_N)_F}{1 - \left(\frac{d_2}{d_3}\right)^2}$$ (based on flare base area) (See calculation table.)

$(C_N)_{cone\text{-}cylinder\text{-}flare}$

$$C_N = (C_N)_{cone\text{-}cyl.} + (\Delta C_N)_F \left(\frac{d_3}{d_2}\right)^2$$ (based on cone-cylinder maximum frontal area) (See calculation table.)

Solution:

$C_D(\alpha) = C_N \alpha$ (Equation 4.2.3.2-n)

4.3 WING-BODY, TAIL-BODY COMBINATIONS AT ANGLE OF ATTACK

4.3.1 WING-BODY LIFT

4.3.1.2 WING-BODY LIFT-CURVE SLOPE

When a lifting panel is added to a body at low angles of attack, certain mutual interference effects may arise between the components. These can be classified as (a) the effect of body upwash or cross flow on the local angle of attack of the lifting panel, (b) the effect of local body-flow properties such as Mach number and dynamic pressure on the panel characteristics, (c) the effect of the lift carryover from the panel onto the body, (d) the effect of panel upwash on the body ahead of the panel (at subsonic speeds only), and (e) the effect of the panel lifting vortices on the body behind the wing. These interferences are generally small for configurations with large panel-span-to-body-diameter ratios typified by conventional, long-range subsonic aircraft. For these configurations the lift-curve slope of the combination is essentially the sum of the lift-curve slopes of the components. For configurations in which the panel-span-to-body-diameter ratio is small, such as conventional missiles or canard surfaces, these interference effects must usually be considered.

A. SUBSONIC

At subsonic speeds the wing-body (tail-body) interference effects are particularly difficult to estimate. Each of the interference effects discussed in the introduction is discussed below for this speed regime.

Body Upwash (Cross Flow)

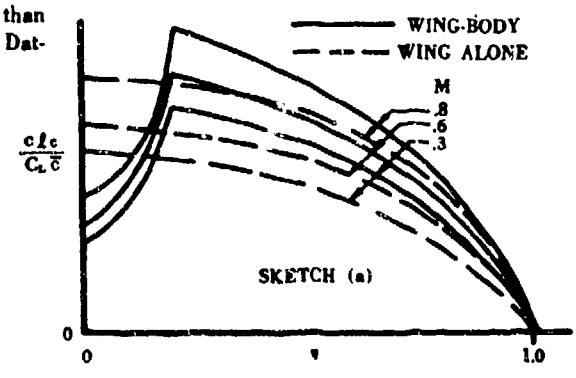
In potential flow, a cylinder with the axis normal to the flow has a maximum velocity at the ends of the diameters normal to the flow equal to twice the free-stream velocity. An inclined cylinder can be treated by considering the cylinder to be in a combined axial and cross flow. The cross-flow velocity is thus equal to $2V\sin\alpha$ and serves to increase the local angle of attack of the lifting panel. In practice only about 40 percent of the full potential velocity is attained (see reference 1).

Body Flow Field (Axial Flow)

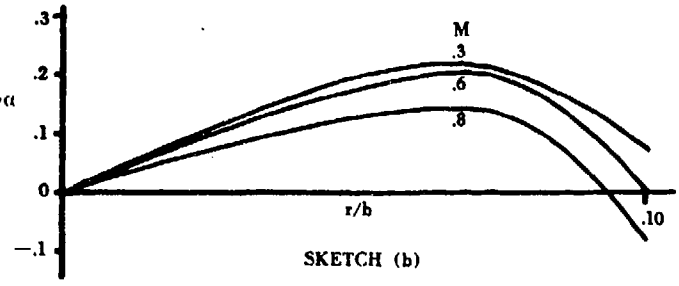
The perturbations in the potential flow field about a three-dimensional body are less than those for a corresponding two-dimensional body. For example, the local velocity about a three-dimensional body varies as $1/r^2$ and about a two-dimensional body as $1/r$, where r is the distance from the body centerline. Nevertheless, the effects of these perturbations can become significant and have sometimes been used in refined design analysis. However, for purposes of the Datcom, these effects are considered to be outside the scope of the book. Reference 2 contains a theoretical development that uses a distributed source-sink and doublet representation for elongated bodies. This method is best suited to machine computation.

Panel Lift Carryover

The carryover of the panel loading onto the body is calculated in reference 3 by means of a conformal mapping procedure. The lift that includes this carryover effect is always less than the lift of the gross panel. No method is included in the Datcom at the present time for estimating this effect.



The combined effect of the lift carryover and the body upwash is shown for several Mach numbers in sketch (a) above. The comparison of the isolated panel and the combination indicates that these two effects tend to compensate for each other. The increment in lift-curve slope due to these effects is shown in sketch (b) as a function of body size and Mach number. The smaller bodies tend to increase the lift-curve slope and the larger bodies tend to decrease it.



SKETCH (b)

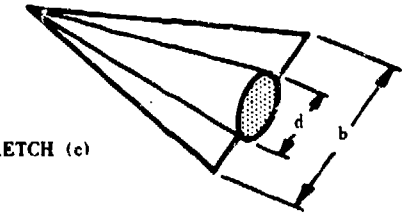
Panel Upwash

The induced effects of the bound and trailing vortices of the panel are such as to cause an upwash ahead of the panel. The upwash is a maximum at the panel leading edge and rapidly decays with distance forward. These effects are more important for pitching-moment considerations than for lift.

Panel Vortices

The downwash behind the panel due to the bound and trailing vortices reduces the effective angle of attack on the aft portion of the body and hence reduces the body lift. Again the effect on the lift of the combination is invariably small; whereas the effect on pitching moment is more significant. These latter two effects have been successfully treated by Multhopp (reference 4).

A simple, yet relatively accurate, approach to the problem of wing-body interference is given in reference 5. In this reference a method based primarily on slender-body theory is presented for calculating the ratio of the lift of the wing-body combination to that of the wing alone. The derivation of the interference effects in terms of these ratios permits the extension of the method to nonslender configurations. The reason for this is that in certain instances slender-body theory accurately predicts the ratio of the wing-body lift to wing lift, even though it does not accurately predict the magnitudes of the individual lift-curve slopes.



SKETCH (c)

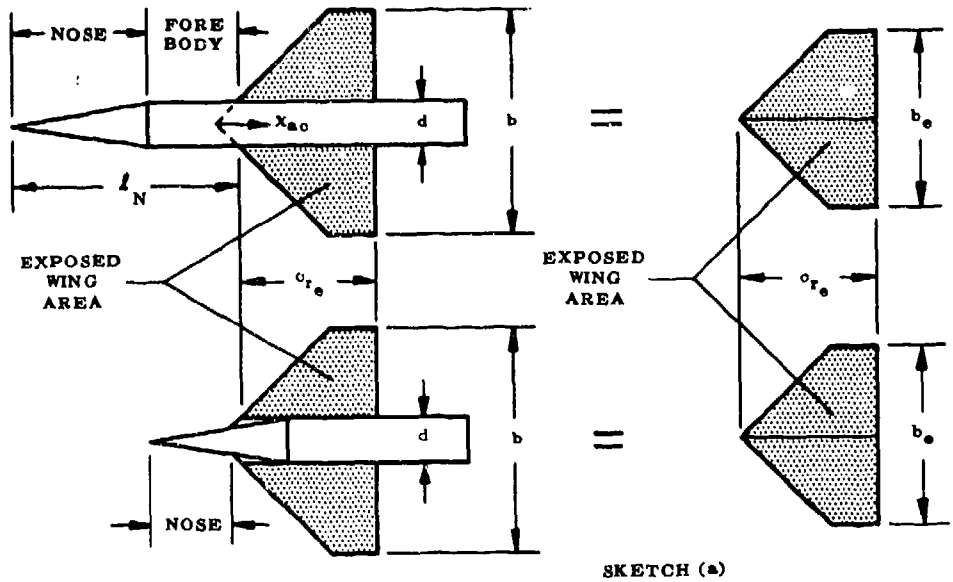
The specific case of a conical body mounted on a delta wing (sketch (c)) has been solved by Spreiter in reference 6. Slender-body theory is used to obtain the ratio of the wing-body lift to that of the wing alone. Correlation with experimental data by this method is good throughout the speed range. In this Section, charts are presented for the determination of the appropriate wing-body interference ratios by means of the methods of references 5 and 6.

The methods are applicable to axisymmetric bodies in combination with straight-taper wings and are restricted to unbanked wings (zero roll angle). According to the limitations of slender-body theory, the methods of references 5 and 6 are not applicable to wings with sweptback trailing edges. Nevertheless, experimental data (see sample problems) indicate that good correlations can be obtained for these configurations.

The definition of exposed wing area depends upon the geometry of the wing-body combination. Two cases are illustrated in sketch (d) below. For a wing mounted on a cylindrical portion of a body the exposed wing is defined as the exposed half-wings joined together. For a wing mounted on an expanding section of a body the exposed wing is defined as the parts of the wing outboard of the largest body diameter at the wing-body intersection.

When the wing is mounted on a cylindrical body section, the nose of the body is defined as the section of the body ahead of the wing. When the wing is mounted on an expanding portion of the body, the nose is defined as the expanding portion of the body.

The latter definition is recommended in reference 5 for the case of a configuration with a small body-diameter-to-wing-



SKETCH (a)

span ratio; but for the case of a relatively large body-diameter-to-wing-span ratio with the wing extending the entire length of the body (see sketch (c)), the use of this definition can lead to substantial error.

DATCOM METHODS

Method 1 (reference 5)

This method is applicable to configurations such as those in sketch (d). The lift on a wing-body combination is taken to be the sum of three principal components:

1. Lift on nose including forebody (see sketch (d), upper configuration)
2. Lift on wing in presence of body
3. Lift on body due to the wing

Two cases of wing-body interference are considered. The first case is that in which the wing incidence is fixed relative to the body and the angle of attack is varied for the wing-body combination as a unit. The second case is that in which the body angle of attack remains fixed and the wing incidence varies relative to the body.

For the first case — wing fixed at zero incidence — the equation for wing-body lift-curve slope based on the total projected wing area, including that intercepted by the fuselage, is:

$$(C_{L_\alpha})_{WB} = \left[K_N + K_{W(B)} + K_{B(W)}\right](C_{L_\alpha})_e \frac{S_e}{S_W} \qquad 4.3.1.2\text{-a}$$

The quantities K_N, $K_{W(B)}$, and $K_{B(W)}$ represent the ratios of the nose lift, the wing lift in the presence of the body, and the body lift in the presence of the wing, respectively, to the wing-alone lift. For wings mounted on expanding bodies, the same procedure, with application of the definitions of sketch (d) in the discussion, usually yields satisfactory results. Configurations similar to that of sketch (c) are treated separately, in later paragraphs.

For the second case — fuselage fixed at zero angle of attack and wing incidence varying — the equation is:

$$(C_{L_i})_{WB} = \left[k_{W(B)} + k_{B(W)}\right](C_{L_\alpha})_e \frac{S_e}{S_W} \qquad 4.3.1.2\text{-b}$$

For both equations above, the best results are obtained for configurations in which the body radii do not exceed 80 percent of the total wing semispan. For larger ratios, the aerodynamic characteristics of the combination tend to be determined more by the body than by the wing.

The parameters common to equations 4.3.1.2-a and 4.3.1.2-b are determined as follows:

S_W = total projected wing area

S_e = exposed wing area. Exposed wing is defined as the exposed half-wings joined together for configurations in which the wing is mounted on a cylindrical section of the body (see sketch (d), upper configuration). For wings on expanding portions of bodies, the exposed wing area is the area outside of the maximum body diameter (see sketch (d), lower configuration).

$(C_{L_\alpha})_e$ = lift-curve slope of exposed wing based on exposed wing area and exposed aspect ratio. Determine from Section 4.1.3.2.

$$K_N = \frac{(C_{L_\alpha})_N S_{N_{ref}}}{(C_{L_\alpha})_e S_e}$$

$(C_{L_\alpha})_N$ = nose lift-curve slope. In most cases a value of 2 per radian (based on body frontal area) is sufficiently accurate. For cases where a higher degree of accuracy is required, use Section 4.2.1.1.

$S_{N_{ref}}$ = reference area for nose lift-curve slope, usually πr^2

$K_{W(B)}^*$ is obtained from figure 4.3.1.2-10

$K_{B(W)}^*$ is obtained from figure 4.3.1.2-10

$k_{W(B)}$ is obtained from figure 4.3.1.2-12a

$k_{B(W)}$ is obtained from figure 4.3.1.2-12a

Method 2 (reference 6)

This method is applicable to configurations similar to that of sketch (c).

The wing-body lift-curve slope is given by the following equation:

$$(C_{L_\alpha})_{WB} = K_{(WB)} (C_{L_\alpha})_W \qquad 4.3.1.2\text{-c}$$

where

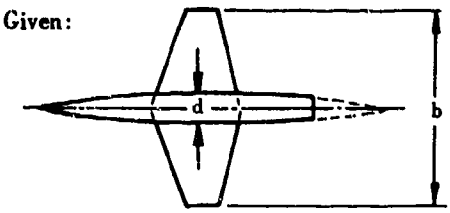
$(C_{L_\alpha})_W$ is the wing lift-curve slope from section 4.1.3.2 (based on total wing area)

$K_{(WB)}$ is obtained from figure 4.3.1.2-12c

Comparison between experimental and calculated wing-body characteristics for a large number of cases (reference 5) shows that the lift of the wing-body combination is generally estimated by these methods to within ±10 percent.

Sample Problem

Given:



$A = 3$

$\Lambda_{LE} = 19.1°$

$\lambda = 0.4$

$\frac{d}{b} = 0.145$

Compute:

$\lambda_e = 0.438$

$A_e = 2.74$

$\frac{S_e}{S_w} = 0.802$

$\frac{S_{N_{ref}}}{S_e} = 0.0617$

$\Lambda_{c/2} = 0$

$(C_{L_\alpha})_e = 3.23$ (figure 4.1.3.2-49)

$$K_N = \frac{(C_{L_\alpha})_N \; S_{N_{ref}}}{(C_{L_\alpha})_e \quad S_e} = \frac{2}{3.23}(.0617) = 0.037$$

*The calculation (Reference 10) of the sum of $K_{W(B)}$ and $K_{B(W)}$ can be expressed in terms of the planform geometry as follows

$$K_{W(B)} + K_{B(W)} = \left(\frac{d}{b} + 1\right)^2.$$

$M = .25$ $K_{W(B)} = 1.12$ (figure 4.3.1.2-10)

$R_l = 2 \times 10^6$ to 8×10^6 (based on wing MAC) $K_{B(W)} = 0.20$ (figure 4.3.1.2-10)

Note: This is configuration 4 of reference 7

Solution:

$$(C_{L_\alpha})_{WB} = \left[K_N + K_{W(B)} + K_{B(W)} \right] (C_{L_\alpha})_e \frac{S_e}{S_w} = 3.51 \text{ per radian (equation 4.3.1.2-a)}$$

This compares with an experimental value of $(C_{N_\alpha})_{WB} = 3.33$ (figures 6 and 21 of reference 7).

B. TRANSONIC

For slender wing-body configurations, the aerodynamic interference effects are relatively insensitive to Mach number, and slender wing-body theory gives reasonable results. For nonslender configurations transonic interference effects can become quite large and sensitive to minor changes in local contour. At present, these effects cannot be predicted with any accuracy.

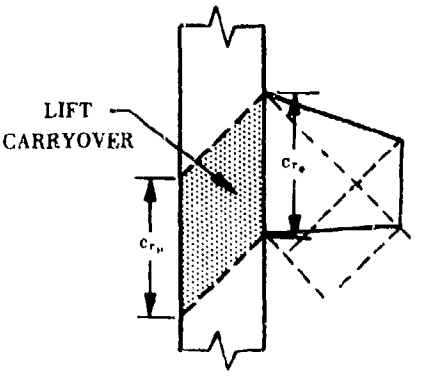
DATCOM METHOD

The method, which is based on slender-body theory, presented in Paragraph C below should be applied at transonic speeds.

C. SUPERSONIC

The mutual aerodynamic interference between a panel and a body at supersonic speeds at low angles of attack is due primarily to the upwash of the body and the lift carryover of the panel onto the body. The body upwash appears similar to its subsonic counterpart, that is, the upwash is a maximum at the body surface and decays with increasing distance from the surface. The integrated effect over the span of the panel at positive angles of attack increases the lift-curve slope of the panel.

The lift carryover on the body is displaced downstream parallel to the Mach lines, as illustrated in sketch (e) below. Important lift and moment differences can therefore exist between configurations in which the fuselage terminates at the wing trailing edge and those in which the fuselage extends beyond the wing trailing edge.



SKETCH (e)

These effects have been adequately predicted by slender-body theory in references 5 and 6 (see paragraph A above).

The local Mach-number and dynamic-pressure-ratio perturbations due to the axial flow component can also cause significant changes in the characteristics of the panels when the local body slopes in the vicinity of the panel become large. These perturbations decay with increasing distance from the body surface. This decay is more rapid than that in the corresponding two-dimensional case, because of the three-dimensional aspect of the body flow field. Sudden changes

in contour like flare or boattail corners, cause a two-dimensional Mach-number and dynamic-pressure-ratio change at the surface that then decays in a three-dimensional manner. Two-dimensional compression values for dynamic pressure and Mach number are given by equations 4.4.1-z and 4.4.1-aa, respectively, and corresponding expansion values are given in figure 4.4.1-74. The average values of these parameters acting on a panel are always less than the two-dimensional values.

DATCOM METHODS

Two methods are presented for estimating the lift-curve slope of wing-body or tail-body combinations. These methods, which are based on slender wing-body theory, are the same as those used in the subsonic paragraph.

Method 1:

Two cases are presented: (a) panel fixed at zero incidence to the body and angle of attack of the combination varied and (b) body kept at zero angle of attack and wing incidence varied. The lift is given by the following equations:

$$\text{(a)} \qquad (C_{L_\alpha})_{WB} = \left[K_N + K_{W(B)} + K_{B(W)}\right](C_{L_\alpha})_e \frac{S_e}{S_w} \tag{4.3.1.2-a}$$

$$\text{(b)} \qquad (C_{L_i})_{WB} = \left[k_{W(B)} + k_{B(W)}\right](C_{L_\alpha})_e \frac{S_e}{S_w} \tag{4.3.1.2-b}$$

The basic definitions and limitations for these equations are the same as those discussed in paragraph A above. However, special care must be used in specifying the "k" factors. These are summarized for the supersonic speed regime below.

$K_N = \dfrac{(C_{L_\alpha})_N S_{N_{ref}}}{(C_{L_\alpha})_e S_e}$

$K_{W(B)}$ all planforms use figure 4.3.1.2-10

$K_{B(W)}$

- triangular-type planforms
  - If $\beta A_e \leq 1$, use figure 4.3.1.2-10
  - If $\beta A_e > 1$,
    - and the fuselage extends beyond wing trailing edge, use figure 4.3.1.2-11a
    - and the fuselage does not extend beyond the wing trailing edge, use figure 4.3.1.2-11b
- nontriangular planforms
  - If $\beta A_e(1 + \lambda_e)\left(\dfrac{\tan \Lambda_{LE}}{\beta} + 1\right) \leq 4$, use figure 4.3.1.2-10
  - If $\beta A_e(1 + \lambda_e)\left(\dfrac{\tan \Lambda_{LE}}{\beta} + 1\right) > 4$,
    - and fuselage extends beyond wing trailing edge, use figure 4.3.1.2-11a
    - and fuselage does not extend beyond wing trailing edge, use figure 4.3.1.2-11b

$k_{W(B)}$ is obtained from figure 4.3.1.2-12b

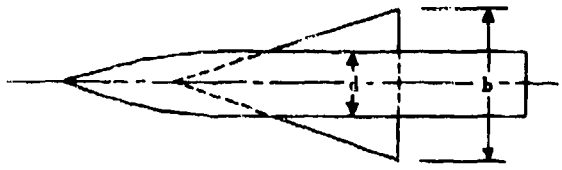
$k_{B(W)}$ is obtained from figure 4.3.1.2-12a

Method 2:

This method is applicable to configurations similar ot that of sketch (c) and is identical to that presented as Method 2 of paragraph A.

1. Supersonic Lift-Curve Slope of Wing-Body Combination

Given:



$A = 1.34$

$\Lambda_{LE} = 71.6°$

$\lambda = 0$

Airfoil: 8-percent-thick double wedge (free-stream direction)

$\frac{d}{b} = 0.428$

$M = 2.02$

$R = 2.6 \times 10^6$ (based on root chord)

Note: This is configuration 2 of reference 8.

Compute:

$\lambda_e = 0$

$A_e = 1.34$

$\frac{S_e}{S_W} = 0.328$

$\frac{S_{N\ ref}}{S_e} = 0.590$

$\beta = 1.75$

$A_e \tan \Lambda_{LE} = 4$

$\frac{\beta}{\tan \Lambda_{LE}} = 0.584$

$[(C_{N_\alpha})_e]_{theory} = 1.65$ (Section 4.1.3.2)

$\frac{(C_{N_\alpha})_e}{[(C_{N_\alpha})_e]_{theory}} = 0.94$ (Section 4.1.3.2) based on $\delta_\perp = 14.5°$

$(C_{N_\alpha})_e = 1.55$

$\frac{\beta}{f_N} = 0.526$

$(C_{N_\alpha})_N = 2.47$ (Section 4.2.1.1)

$K_{W(B)} = 1.38$ (figure 4.3.1.2-10)

$\frac{\beta d}{c_{r_e}} = 0.875$

$K_{B(W)}\, \beta\, (C_{L_\alpha})_e\, (\lambda_e + 1)\left(\frac{b}{d} - 1\right) = 2.1$ (figure 4.3.1.2-11a)

$\beta\, (\lambda_e + 1)\left(\frac{b}{d} - 1\right) = 2.35$

$K_{B(W)} = 0.576$

$K_N = \frac{(C_{N_\alpha})_N}{(C_{N_\alpha})_e} \quad \frac{S_{N\ ref}}{S_e} = 0.936$

Solution:

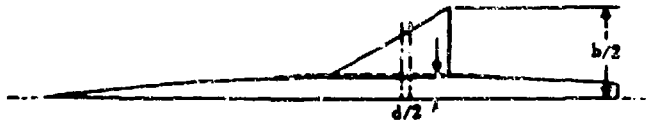
$$(C_{L_\alpha})_{WB} = [K_N + K_{W(B)} + K_{B(W)}]\,(C_{L_\alpha})_e\, \frac{S_e}{S_W} = 1.47 \text{ (equation 4.3.1.2-a)}$$

This compares with an experimental value of $(C_{L_\alpha})_{WB} = 1.57$ from reference 8.

2. Supersonic Lift-Curve Slope — Wing in Presence of Body

Case One: Wing incidence fixed at $i_w = 0$, fuselage rotating with wing

Given:



$A = 2.3$

$\Lambda_{LE} = 60°$

$\lambda = 0$

Airfoil: 9-percent-thick biconvex (free-stream direction)

$\frac{d}{b} = 0.23$

$M = 1.9$

$R_l = 1.9 \times 10^6$ (based on root chord)

Note: This is the delta-wing configuration in reference 9.

Compute:

$\lambda_e = 0$

$A_e = 2.31$

$\beta = 1.62$

$A_e \tan \Lambda_{LE} = 4$

$\frac{\beta}{\tan \Lambda_{LE}} = .935$

$[(C_{N_\alpha})_e]_{theory} = 2.38$ (Section 4.1.3.2)

$\frac{(C_{N_\alpha})_e}{[(C_{N_\alpha})_e]_{theory}} = .75$ (Section 4.1.3.2) based on $\delta_\perp = 20.7°$

$(C_{N_\alpha})_e = 1.79$

$K_{W(B)} = 1.2$ (figure 4.3.1.2-10)

Solution:

Since only the lift on the wing is of interest, the reference area is the exposed wing area, and equation 4.3.1.2-a reduces to

$$(C_{L_\alpha})_{w_e(B)} = K_{W(B)} (C_{L_\alpha})_e$$

Thus the wing lift in the presence of the body is $(C_{L_\alpha})_{w_e(B)} = 2.15$

The experimental value from reference 9 is $(C_{L_\alpha})_{w_e(B)} = 2.22$

Case Two: Body fixed at $\alpha = 0$, wing incidence variable

Given:

Same as Case One

Compute:

$k_{W(B)} = 0.96$ (figure 4.3.1.2-12b)
Other coefficients same as in Case One

Solution:

Again only the wing lift is of interest. Equation 4.3.1.2-b becomes

$$(C_{L_\alpha})_{w_e(B)} = k_{W(B)} (C_{L_\alpha})_e$$
$$= 1.72$$

The experimental value from reference 9 is 1.67.

4.3.1.3 WING-BODY LIFT IN THE NONLINEAR ANGLE-OF-ATTACK RANGE

The mutual interference factors that influence the lift of a wing-body or a tail-body combination at low angles of attack (see Section 4.3.1.2) are also present at higher angles of attack. These include the nonlinear characteristics of the basic wing and body components (see Sections 4.1.3.3 and 4.2.1.2, respectively).

In addition, at angles of attack of approximately six degrees body vortices appear that can have strong influences on the loading on the lifting panels. The flow separates just behind or above the area of minimum pressure along the side of the body near the nose and wraps up into a pair of symmetrical vortices that proceed downstream in a nearly free-stream direction. The point at which separation first takes place depends upon the angle of attack (the higher the angle of attack, the nearer the nose separation occurs), the nose profile shape (the blunter the nose, the nearer the nose separation occurs), and body cross-sectional shape (sharply curving lateral contours promote early separation). The vortices increase in size and strength with increasing downstream distance. Since their strength also increases as the square of the angle of attack, they become quite significant at the higher angles of attack.

Quantitatively, these vortices do not change significantly between subsonic and supersonic speeds. This fact is substantiated by reference 1, which derives from supersonic data a method of estimating the cross-flow lift that gives equally reliable answers at subsonic and supersonic speeds. This is the method presented by the Datcom for handling the effects of these vortices on lifting surfaces at both subsonic and supersonic speeds.

A. SUBSONIC

Two methods of estimating the lift of wing-body configurations in the nonlinear angle-of-attack range are presented. The first uses the estimated nonlinear lift characteristics of isolated wings and bodies corrected by the slender-body interference factors used in Section 4.3.1.2. The effects of the body vortices are then added. This method is valid up to high angles of attack and is the more accurate of the two methods, though more laborious to use.

The second method simply uses the linear methods of Section 4.3.1.2 and adds the effects due to the body vortices. This method can be used with a minimum of effort but is less accurate than the first method because it does not include the nonlinearities of the basic components.

DATCOM METHODS

Method 1

The variation of lift with angle of attack is determined by the equation

$$C_N = \left\{(C_N)_N \frac{S_{N_{ref}}}{S_e} + \left[K_{W(B)} + K_{B(W)}\right](C_N)_e\right\}\frac{S_e}{S_W} + I_{v_{B(W)}}\left(\frac{\Gamma}{2\pi a V r}\right)\frac{r}{b_W/2}\frac{q}{q_\infty}\alpha\left(C_{L_\alpha}\right)_W \qquad 4.3.1.3\text{-a}$$

where

$(C_N)_N$ is the nose normal-force coefficient at a given angle of attack based on body frontal area $S_{N_{ref}}$ from Section 4.2.1.2

$K_{W(B)}$ and $K_{B(W)}$ are the mutual linear-theory interference values from figure 4.3.1.2-10

$(C_N)_e$ is the normal-force coefficient, at any given angle of attack, for the exposed wing (calculated by the method of Section 4.1.3.3 and based on exposed wing area)

$I_{v_{B(W)}}$ is the vortex interference factor for a lifting surface mounted on the body center line. This factor is given in figures 4.3.1.3-7a through 4.3.1.3-7ℓ for various wing taper ratios, relative wing sizes, and vortex-center line positions. In using these figures a possible problem can develop when interpolation must be made with respect to λ and $r/(b_W/2)$. For positions of the vortex near the body, the interpolation in $r/(b_W/2)$ can carry the vortex inside the body. Under these circumstances, it is recommended that the interpolation be made using $(y_o - r)/(b_W/2 - r)$ for the vortex lateral position in place of $y_o/(b_W/2)$, to avoid vortex positions inside the body. These figures are derived by means of strip theory in reference 2.

The vertical and lateral vortex positions at any given longitudinal station x can be determined from figures 4.3.1.3-13b and 4.3.1.3-14, respectively. These figures are based on the data of references 3, 4, and 5, for an ogive-cylinder, a cone-cylinder, and a modified cone-cylinder, respectively. The longitudinal position of vortex separation used in these figures is obtained from figure 4.3.1.3-13a, which is based on the ogive-cylinder test at a Mach number of 1.98 from reference 3.

$\frac{\Gamma}{2\pi a Vr}$ is the nondimensional vortex strength from figure 4.3.1.3-15, which is also based on the data of references 3, 4, and 5.

$\frac{r}{b_W/2}$ is the ratio of the radius of the body at the midpoint of the exposed root chord of the lifting panel to the semispan of the panel.

q/q_∞ is the dynamic pressure ratio acting on the panel. This value can either be assumed to be unity or can be estimated, with the information in Section 4.4.1 as a guide.

$(C_{L_\alpha})_W$ is the lift-curve slope of the isolated gross panel from Section 4.1.3.2.

Method 2

The variation of lift with angle of attack is given by the equation

$$C_L = \left[K_N + K_{W(B)} + K_{B(W)} \right] (C_{L_\alpha})_e \alpha \frac{S_e}{S_W} + I_{v_{B(W)}} \left(\frac{\Gamma}{2\pi a Vr} \right) \frac{r}{b_W/2} \frac{q}{q_\infty} \alpha \left(C_{L_\alpha} \right)_W \qquad 4.3.1.3\text{-b}$$

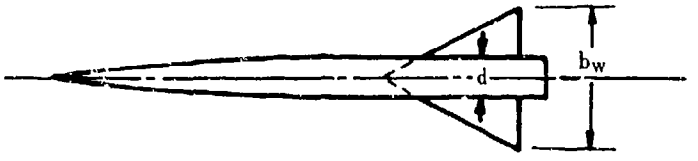
where the first term on the right-hand side is given by the method presented in Section 4.3.1.2 and the second term is determined as in Method 1.

The last terms of equations 4.3.1.3-a and -b, respectively, which represent the contributions of the body vortices, can normally be ignored for normal airplane-type wing-body combinations. For conventional missile configurations, these effects may become sizable.

Sample Problems

1. Method 1

Given:



$A_W = A_e = 2$

$\Lambda_{c/2} = 45°$

$\lambda_W = \lambda_e = 0$

$\frac{S_e}{S_W} = 0.518$

$\frac{d}{b_W} = 0.280$

Airfoil: NACA 0005

$M = 0.2$

$q/q_\infty = 1.0$

$\frac{S_{N_{ref}}}{S_e} = 0.238$

$\frac{r}{b_W/2} = 0.280$

$\frac{x}{r} = 21.10$

where

x = distance from nose to c/4-point of the MAC of the exposed wing panel.

The following lift variation with angle of attack (from test data)

α(deg)	$(C_N)_N$	$(C_N)_e$
0	−.010	0
4	.035	.150
8	.175	.300
12	.430	.430
16	.810	.700

$(C_N)_N$ is based on $S_{N_{ref}}$

$(C_N)_e$ is based on S_e

The following lift-curve slopes

$(C_{L_\alpha})_e$ = 2.12 per radian (test data)

$(C_{L_\alpha})_W$ = 2.34 per radian (methods of Section 4.1.3.2)

$(C_{L_\alpha})_N$ = 2 per radian (slender-body theory)

$(C_{L_\alpha})_e$ based on S_e

$(C_{L_\alpha})_W$ based on S_W

$(C_{L_\alpha})_N$ based on $S_{N_{ref}}$

Compute:

$$\left.\begin{aligned} K_{W(B)} &= 1.240 \\ K_{B(W)} &= 0.420 \end{aligned}\right\} \text{(figure 4.3.1.2-10)}$$

The lift variation with angle of attack for the wing-body configuration, excluding the effect of body vortices, is calculated as follows:

$$\frac{C_L}{\cos\alpha} \approx C_N = \left\{(C_N)_N \frac{S_{N_{ref}}}{S_e} + \left[K_{W(B)} + K_{B(W)}\right](C_N)_e\right\}\frac{S_e}{S_W} \text{ (equation 4.3.1.3-a)}$$

α deg	C_N without vortices effect	$C_L = C_N \cos\alpha$
0	−.001	−.001
4	.133	.133
8	.280	.277
12	.423	.414
16	.701	.674

The calculation procedure for the effect of body vortices on lift variation with angle of attack is shown below.

$\frac{X_s}{r}$ (figure 4.3.1.3-13a)

$$\frac{X}{r} - \frac{X_s}{r} = 21.10 - \frac{X_s}{r}$$

$$\alpha\left(\frac{X}{r} - \frac{X_s}{r}\right) (\alpha \text{ in radians})$$

$\frac{x_o}{r}$ (figure 4.3.1.3-13b)

$\frac{y_o}{r}$ (figure 4.3.1.3-14)

$\frac{\Gamma}{2\pi a V_r}$ (figure 4.3.1.3-15)

$$\frac{y_o}{b_w/2} = \frac{y_o}{r}\frac{r}{b_w/2}$$

$$\frac{x_o}{b_w/2} = \frac{x_o}{r}\frac{r}{b_w/2}$$

$I_{v_{B(W)}}$ (figures 4.3.1.3-7a., 4.3.1.3-7b., and 4.3.1.3-7c, interpolated for $\frac{r}{b_w/2} = 0.280$)

$$\frac{r}{b_w/2}\frac{q}{q_\infty}(C_{L_\alpha})_W \alpha = 0.280\ (1.0)\ (.0408)\ \alpha^\circ = 0.0114\alpha^\circ$$

The solution for the vortices effect is

$$I_{v_{B(W)}}\left(\frac{\Gamma}{2\pi a V_r}\right)\frac{r}{b_w/2}\frac{q}{q_\infty}\alpha\left(C_{L_\alpha}\right)_W \quad (\alpha \text{ in degrees})$$

The details of the calculation for vortices effect are shown below.

① α deg	② $\frac{x_o}{r}$	③ $\alpha\left(\frac{x}{r} - \frac{x_o}{r}\right)$	④ $\frac{y_o}{r}$	⑤ $\frac{x_o}{r}$	⑥ $\frac{\Gamma}{2\pi a V_r}$

16	.674	−.0783	.596

2. Method 2

Given:

The same configuration and characteristics as in Method 1 above.

Compute:

$$K_N = \frac{(C_{L_\alpha})_N}{(C_{L_\alpha})_*} \frac{S_{N_{ref}}}{S_*} \quad \text{(Section 4.3.1.2)}$$

$$= \frac{2}{2.12} (.238)$$

$$= 0.225$$

$$\left.\begin{aligned} K_{W(B)} &= 1.240 \\ K_{B(W)} &= 0.420 \end{aligned}\right\} \text{ see Method 1 above}$$

The lift variation with angle of attack for the wing-body configuration, excluding the effect of body vortices, is calculated as follows:

$$C_L = [K_N + K_{W(B)} + K_{B(W)}] \frac{S_*}{S_W} (C_{L_\alpha})_* \alpha \ (\alpha \text{ in degrees})$$

$$= [.225 + 1.240 + .420] (.518) (.0370) \alpha$$

$$= 0.03613 \alpha \ (\alpha \text{ in degrees})$$

The lift due to body vortices is the same as that calculated in Method 1 above. The total lift variation is shown below.

α deg	① C_L without vortices effect	② C_L due to body vortices	③ C_L = ① + ②
0	0	—	0
4	.144	—	.144
8	.289	−.0102	.279
12	.434	−.0348	.399
16	.578	−.0783	.500

B. TRANSONIC

At transonic speeds compression and expansion waves interact at much greater distances from the body than at supersonic speeds. The disturbances in the flow field extend to greater distances from the body surface than at subsonic or supersonic speeds. With a knowledge of conditions at the surface of a body, the characteristics of a lifting surface mounted on the body can be approximated by assuming that the flow disturbances propagate undiminished in a direction normal to the free stream. An excellent discussion of methods of calculating surface pressures on bodies of revolution at zero angle of attack is given in reference 6. However, the corresponding problem at angle of attack is not well covered in the literature.

At angle of attack, the appearance of body vortices due to viscous separation effects is exactly analogous to that which occurs at subsonic or supersonic speeds.

DATCOM METHOD

No explicit method is presented in the Datcom at the present time, because of the complexity and uncertainty of estimating nonviscous transonic flow properties. It is recommended that the methods detailed in paragraph C be used at transonic speeds.

C. SUPERSONIC

The discussion of the potential flow field about a body at angle of attack, given in Section 4.2.1.2 is directly applicable to this Section, and therefore no new information is presented. Body vortices are also present at angles of attack in excess of approximately 6°. The physical mechanism of these vortices and their effect upon lifting panels are the same as at subsonic speeds; they are discussed in some detail in paragraph A.

DATCOM METHOD

Two methods are available for estimating the lift of wing-body configurations at supersonic speeds. These can be represented by equations 4.3.1.3-a and -b, respectively, of paragraph A. Because of the similarity of the application of these methods, the sample problem of paragraph A suffices to illustrate these methods.

4.3.1.4 WING-BODY MAXIMUM LIFT

A. SUBSONIC

The addition of a body of revolution to a wing at high angles of attack increases the wing-induced angle of attack at all spanwise stations. The increase is greatest at the root and falls off in an exponential manner with increasing distance from the body.

This effective increase in angle of attack tends to make the wing in the presence of the body stall at a lower geometric angle of attack than that corresponding to the wing alone. However, this tendency to stall at a lower angle of attack may be modified or counteracted by changes in the wing stalling pattern. These changes are the result of the nonlinear spanwise variation of body-induced flow and also of the partial blanketing of the wing by the body. The relative magnitudes of these latter two effects are largely dependent on specific wing planform shape. This means that wing planform shape is a primary parameter in considering wing-body maximum lift.

Varying the wing height on the body, the body cross-section shape, or the body local area distribution (area rule) changes the body-induced effects on the wing and hence the maximum lift of the combination. Experimental data on variations of this type show small but generally consistent differences (see References 1, 2, 3, and 4).

The first method presented below is essentially that of Section 4.1.3.4, in that it requires the user to employ the most accurate wing-body spanwise-loading computer program available. In case no such program is available to the user, an alternate empirical method is presented as Method 2.

DATCOM METHODS

Method 1

This method requires that the user have at his disposal an accurate wing-body spanwise-loading computer program, e.g., a lifting-surface-theory computer program. Specific instructions for application of the program to obtain the wing-body maximum lift are identical to Steps 1 through 4 of Paragraph A in Section 4.1.3.4, which pertain to the wing-alone case.

No substantiation of this method is presented because of the variety of spanwise-loading programs that are available to different Datcom users.

Method 2

This method is based on empirical correlations and the wing-alone method of Section 4.1.3.4, and should be restricted to Mach numbers equal to or less than 0.60. The wing-body maximum lift coefficient and angle of attack at maximum lift are obtained using

$$\left(C_{L_{max}}\right)_{WB} = \frac{\left(C_{L_{max}}\right)_{WB}}{\left(C_{L_{max}}\right)_{W}} \left(C_{L_{max}}\right)_{W} \qquad 4.3.1.4\text{-a}$$

$$(\alpha_{C_{L_{max}}})_{WB} = \frac{(\alpha_{C_{L_{max}}})_{WB}}{(\alpha_{C_{L_{max}}})_{W}} (\alpha_{C_{L_{max}}})_{W} \qquad 4.3.1.4\text{-b}$$

where

$\frac{(C_{L_{max}})_{WB}}{(C_{L_{max}})_{W}}$ is the ratio of the wing-body maximum lift to wing maximum lift, obtained from Figure 4.3.1.4-12b as a function of wing-body geometry.

$(C_{L_{max}})_{W}$ is the wing maximum lift obtained from the appropriate method of Paragraph A in Section 4.1.3.4. The wing-alone value is based on the total wing, including that part covered by the body.

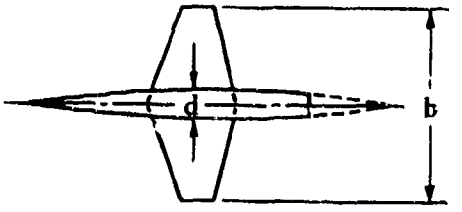
$\frac{(\alpha_{C_{L_{max}}})_{WB}}{(\alpha_{C_{L_{max}}})_{W}}$ is the ratio of the wing-body angle of attack at maximum lift to the wing angle of attack at maximum lift. This value is obtained from Figure 4.3.1.4-12c as a function of wing-body geometry.

$(\alpha_{C_{L_{max}}})_{W}$ is the wing-alone angle of attack at maximum lift obtained from the appropriate method of Paragraph A in Section 4.1.3.4. The wing-alone value is based on the total wing, including that part covered by the body.

A comparison of test data from References 5 through 17 with results calculated by this method is presented in Table 4.3.1.4-A.

Sample Problem

Given: Configuration 4 of Reference 14.



$A = 3.0$ $\Lambda_{LE} = 19.1^{o}$ $\lambda = 0.4$

Airfoil: 3-percent biconvex (free-stream direction)

$\frac{d}{b} = 0.145$ $M = 0.25$ $R_{\ell} = 8.8 \times 10^{6}$

$(C_{L_{max}})_{W} = 0.77$

$(\alpha_{C_{L_{max}}})_{W} = 15.9^{o}$

} Obtained using Section 4.1.3.4

Compute:

$C_2 = 1.10$ (Figure 4.3.1.4-12a)

$$(C_2 + 1) A \tan \Lambda_{LE} = (1.10 + 1)(3)(0.3463) = 2.18$$

$$\frac{\left(C_{L_{max}}\right)_{WB}}{\left(C_{L_{max}}\right)_{W}} = 0.98 \qquad \text{(Figure 4.3.1.4-12b)}$$

$$\frac{(\alpha_{C_{L_{max}}})_{WB}}{(\alpha_{C_{L_{max}}})_{W}} = 0.99 \qquad \text{(Figure 4.3.1.4-12c)}$$

Solution:

$$\left(C_{L_{max}}\right)_{WB} = \frac{\left(C_{L_{max}}\right)_{WB}}{\left(C_{L_{max}}\right)_{W}} \left(C_{L_{max}}\right)_{W} \qquad \text{(Equation 4.3.1.4-a)}$$

$$= (0.98)(0.77)$$

$$= 0.75$$

$$(\alpha_{C_{L_{max}}})_{WB} = \frac{(\alpha_{C_{L_{max}}})_{WB}}{(\alpha_{C_{L_{max}}})_{W}} (\alpha_{C_{L_{max}}})_{W} \qquad \text{(Equation 4.3.1.4-b)}$$

$$= (0.99)(15.9)$$

$$= 15.7^{o}$$

These compare with test-data values from Reference 14 of $\left(C_{L_{max}}\right)_{WB} = 0.71$ and $\left(\alpha_{C_{L_{max}}}\right)_{WB} = 14.3^{o}$

B. TRANSONIC

No method is presented in this speed regime. The lack of sufficient experimental data prevents the presentation of any empirical method. However, the trend of the limited data available (Reference 5) indicates that the wing-body maximum lift converges to the wing-alone value as the Mach number is increased above M = 0.6.

C. SUPERSONIC

Two separate methods are presented in this section for estimating the wing-body maximum lift at supersonic speeds. The first method is somewhat easier to apply than the second method. Both methods yield approximately the same degree of accuracy, based on the limited available test data (References 18, 19, and 20). Attempts to substantiate these methods completely have been impaired by lack of test data in the stall regime.

The first method is based on the application of the wing-body interference coefficients of Section 4.3.1.2 to the exposed-wing-alone maximum lift of Section 4.1.3.4. This approach is justified, since at supersonic and hypersonic speeds the wing lift is limited by geometric considerations rather than by flow separation on the wing. That is, maximum lift is reached when the component of the normal force in the lift direction ceases to increase with angle of attack. Therefore, the body-induced effects are felt mainly through their influence on the lift-curve slope, rather than on wing separation. This implies that the supersonic maximum lift of the wing-body combination may be obtained by applying wing-body interference coefficients to the wing-alone maximum lift value.

The second method uses the method of Section 4.3.1.3 to calculate the complete normal-force curve, from which the lift curve can easily be calculated.

Both methods assume that the angle of attack at wing-body maximum lift is the same as the angle of attack for wing maximum lift.

DATCOM METHODS

Method 1

This method applies the wing-body interference factors from Paragraph C of Section 4.3.1.2 to the wing-alone maximum lift coefficient. The limitations of the sections used in this method will also apply to this method. The wing-body maximum lift, based on S_W, is found by

$$\left(C_{L_{max}}\right)_{WB} = \left(C_{L_{max}}\right)_e \left[K_N + K_{W(B)} + K_{B(W)}\right] \frac{S_e}{S_W} \qquad 4.3.1.4\text{-a}$$

where

$\left(C_{L_{max}}\right)_e$ is the exposed-wing-alone maximum lift coefficient determined by Paragraph C of Section 4.1.3.4. (For the definition of exposed wing, see Section 4.3.1.2)

K_N, $K_{W(B)}$, and $K_{B(W)}$ are the wing-body interference factors from Method 1 of Paragraph C of Section 4.3.1.2.

$\frac{S_e}{S_W}$ is the ratio of the exposed wing area to the total wing area.

No substantiation of this method is presented; however, application of the method is illustrated in Sample Problem 1.

Method 2

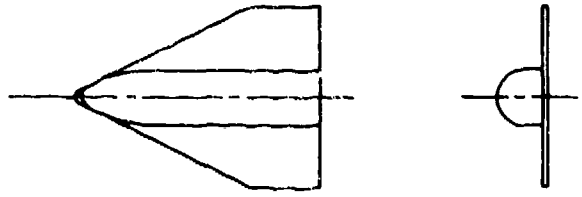
Application of this method is restricted to straight-tapered planforms. The wing-body maximum lift is determined by using Equation 4.3.1.3-a to obtain the normal force C_N as a function of angle of attack. Then the lift curve is constructed by using the approximation $C_L \cong C_N \cos\alpha$, from which the $C_{L_{max}}$ value is obtained. The determination of the nose contribution term $(C_N)_N$ of Equation 4.3.1-3-a may present somewhat of a problem, since the supersonic design curves (Section 4.2.1.2) are inadequate at the higher angles of attack. Consequently, it is suggested that Method 2 of Paragraph D of Section 4.2.1.2 be used for determining $(C_N)_N$ in the high angle-of-attack regime.

No substantiation of this method is presented; however, application of the method is illustrated in Sample Problem 2.

Sample Problems

1. Method 1

Given: The wing-body configuration of Reference 19.



Total Wing:

$A = 1.15$ $\lambda = 0.3$ $b = 8.26$ in. $c_r = 11.0$ in.

$c_t = 3.30$ in. $\Lambda_{LE} = 63^{O}$ $S_W = 0.409$ sq ft Airfoil: flat plate

Exposed Wing:

$A_e = 0.97$ $\lambda_e = 0.354$ $b_e = 6.13$ in. $c_{r_e} = 9.31$ in.

$S_e = 0.268$ sq ft

Additional Characteristics:

$\ell_B = 10.65$ in. $d = 2.13$ in. LER = 0.125 in. $M = 1.97; \beta = 1.70$

Compute:

$\left(C_{L_{max}}\right)_e$

$A_e \tan \Lambda_{LE} = (0.97)(1.963) = 1.904$

$$\frac{\beta}{\tan \Lambda_{LE}} = \frac{1.70}{1.963} = 0.866$$

$\tan \Lambda_{LE} \left(C_{N_\alpha}\right)_{theory} = 3.175$ (Figure 4.1.3.2-56 interpolated)

$$\left(C_{N_\alpha}\right)_{theory} = \frac{3.175}{1.963} = 1.617 \text{ per rad}$$

$$\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}} = 1.0 \text{ for a flat plate} \qquad \text{(Figure 4.1.3.2-60)}$$

$$C_{N_\alpha} = 1.617 \text{ per rad}$$

$$\frac{\beta C_{N_\alpha}}{4} = \frac{(1.70)(1.617}{4} = 0.68?$$

$$\frac{1}{M} = \frac{1}{1.97} = 0.5076$$

$$\left(C_{L_{max}}\right)_e = 0.985 \qquad \text{(Figure 4.1.3.4-27a)}$$

$K_N = 0$, since nose does not extend ahead of wing apex

$K_{W(B)}$

$$\frac{d}{b} = \frac{2.13}{8.26} = 0.258$$

$K_{W(B)} = 1.22$ (Figure 4.3.1.2-10)

$K_{B(W)}$

$$\frac{\beta d}{c_{r_e}} = \frac{(1.70)(2.13)}{9.31} = 0.389$$

$$\beta \cot \Lambda_{LE} = (1.70)(0.5095) = 0.866$$

$$K_{B(W)}\left[\beta\left(C_{L_\alpha}\right)_e\left(\lambda_e + 1\right)\left(\frac{b}{d} - 1\right)\right] = 2.5 \qquad \text{(Figure 4.3.1.2-11b)}$$

$$K_{B(W)} = \frac{2.5}{(1.70)(1.617)(1.354)\left(\frac{8.26}{2.13} - 1\right)} = \frac{2.5}{10.71} = 0.233$$

Solution:

$$\left(C_{L_{max}}\right)_{WB} = \left(C_{L_{max}}\right)_e\left[K_N + K_{W(B)} + K_{B(W)}\right]\frac{S_e}{S_W} \qquad \text{(Equation 4.3.1.4-a)}$$

$$= (0.985)(0 + 1.22 + 0.233)\left(\frac{0.268}{0.409}\right) = 0.937$$

$\alpha_{C_{L_{max}}} = 44.2^{o}$ (Figure 4.1.3.4-27b)

This compares with a test value of $C_{L_{max}} = 0.94$ and $\alpha_{C_{L_{max}}} = 42^{o}$

2. Method 2

Given: Same configuration as Sample Problem 1.

$A = 1.15$ $\lambda = 0.3$ $\Lambda_{LE} = 63^{o}$ $S_W = 0.409$ sq ft

$S_e = 0.268$ sq ft Airfoil: flat plate

$K_{W(B)} = 1.22$

$K_{B(W)} = 0.233$ } (Sample Problem 1, above)

$\left(C_{N_\alpha}\right)_e = 1.617$ per rad

$M = 1.97$; $\beta = 1.70$

Compute:

$\left(C_N\right)_N = 0$, since nose does not extend ahead of wing apex

$\left(C_N\right)_e$

$$\frac{\beta}{\tan \Lambda_{LE}} = \frac{1.70}{1.963} < 1$$ (subsonic leading edge)

Step 1. $\left(C_{N_\alpha}\right)_e = 1.617$

Step 2. Empirical Parameter E (see Paragraph C of Section 4.1.3.3)

$\frac{\tan \Lambda_{LE}}{1.92} = \frac{1.963}{1.92} > 1$, therefore use equation:

$$E = \left(C_{N_\alpha}\right)_e \left[\frac{\tan \Lambda_{LE}}{1.92} + C\left(\frac{\tan \Lambda_{LE}}{1.92} - 1\right)\right]$$

$$\delta_{\perp} = \tan^{-1} \frac{\Delta y_{\perp}}{5.85} = 0 \text{ for flat plate} \qquad \text{(see sketch on Figure 2.2.1-8)}$$

$$C = 0 \qquad \text{(Figure 4.1.3.3-59a)}$$

$$E = (1.617)\left[\frac{1.963}{1.92} + (0)\left(\frac{1.963}{1.92} - 1\right)\right]$$

$$= 1.653 \text{ per rad}$$

Step 3.

$$E\,\frac{\beta}{\tan \Lambda_{LE}} = 1.653\ \frac{1.70}{1.963} = 1.432$$

$$\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}} = 1.0 \text{ for a flat plate} \qquad \text{(Figure 4.1.3.2-60)}$$

$$\frac{\left(C_{N_\alpha}\right)_{theory}}{C_{N_\alpha}}\ \beta \tan \alpha = \beta \tan \alpha;\ \frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}}\ \frac{1}{\beta \tan \alpha} = \frac{1}{\beta \tan \alpha}$$

Step 4.

$$\left(C_N\right)_e = C_{N_\alpha}\ \frac{\sin 2\alpha}{2} + C_{N_{\alpha\alpha}} \sin \alpha |\sin \alpha| \qquad \text{(Equation 4.1.3.3-a)}$$

The contribution of body vortices (last term of Equation 4.3.1.3-a) can be neglected, since the configuration is more typical of an airplane configuration than of a missile.

Solution:

$$C_N = \left\{ \left(C_N\right)_N \frac{S_{N_{ref}}}{S_e} + \left[K_{W(B)} + K_{B(W)}\right] \left(C_N\right)_e \right\} \frac{S_e}{S_W} + I_{v_{B(W)}} \frac{\Gamma}{2\pi\alpha V r} \frac{r}{b_W/2} \frac{q}{q_\infty} \alpha \left(C_{L_\alpha}\right)_W$$

(Equation 4.3.1.3-a)

$$= \left\{0 + [1.22 + 0.233] \left(C_N\right)_e\right\} \left(\frac{0.268}{0.409}\right) + 0$$

$$= 0.952 \left(C_N\right)_e$$

① α (deg)	② $\left(C_N\right)_e$	③ C_N 0.952 ②	④ C_L cos α ③
16	0.5485	0.5222	0.502
20	0.6952	0.6618	0.622
24	0.8357	0.7956	0.727
28	0.9677	0.9213	0.813
32	1.0889	1.0366	0.879
36	1.2043	1.1465	0.928
40	1.3127	1.2497	0.957
44	1.4161	1.3481	0.970
48	1.5054	1.4331	0.959
52	1.5917	1.5153	0.933

These data are plotted in Sketch (a), where $C_{L_{max}} = 0.970$ and $\alpha_{C_{L_{max}}} = 44^o$. These compare with test values of $C_{L_{max}} = 0.94$ and $\alpha_{C_{L_{max}}} = 42^o$.

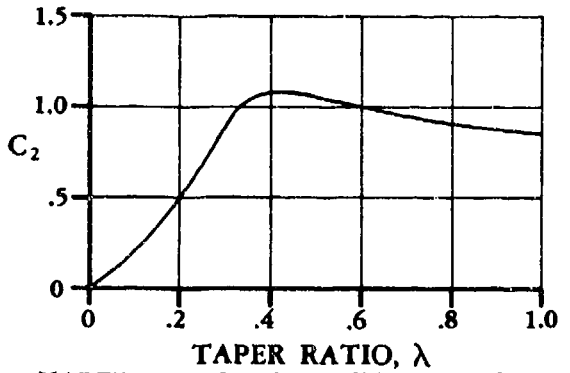

FIGURE 4.3.1.4-12a TAPER-RATIO CORRECTION FACTOR

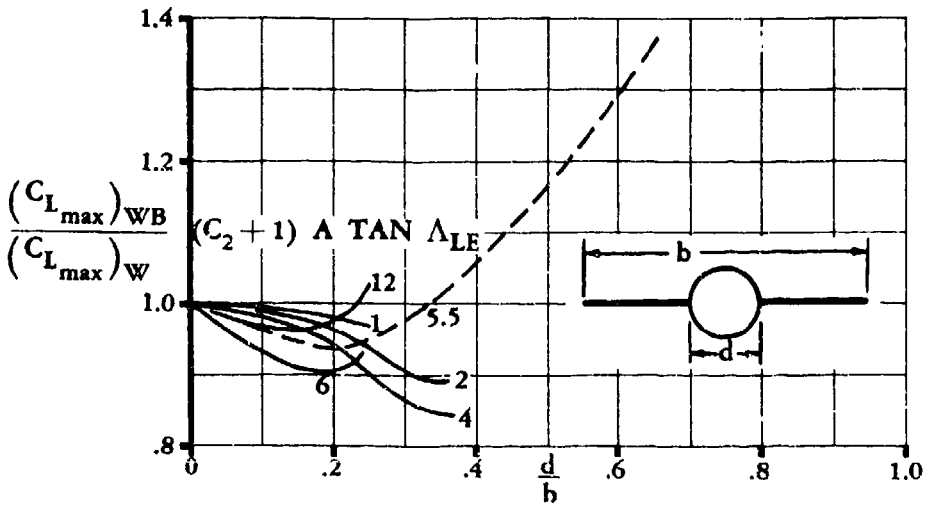

FIGURE 4.3.1.4-12b WING-BODY MAXIMUM LIFT

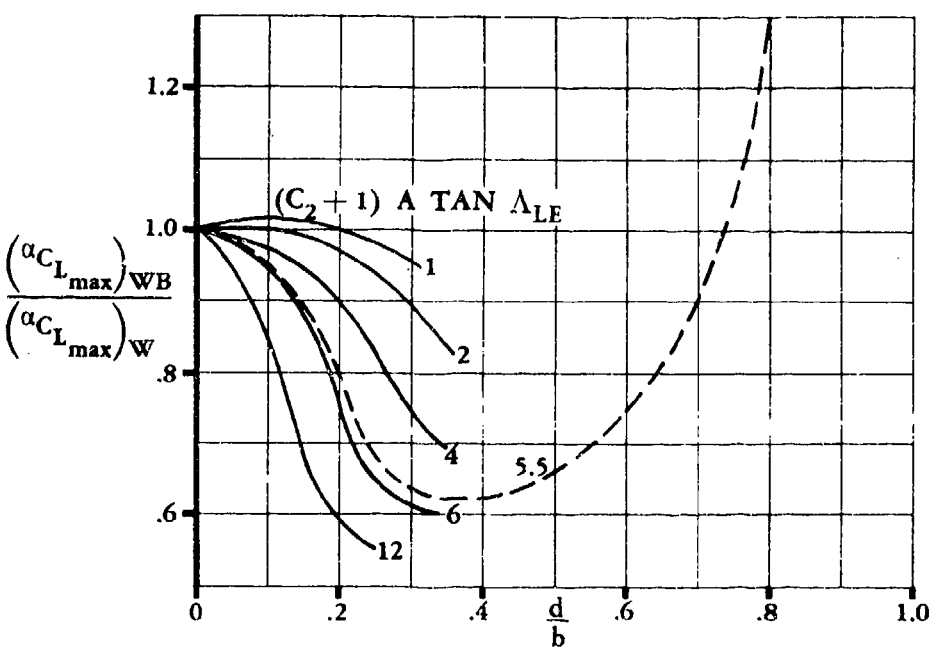

FIGURE 4.3.1.4-12c ANGLE OF ATTACK FOR MAXIMUM LIFT

4.3.2.1 WING-BODY ZERO-LIFT PITCHING MOMENT

Methods are presented for determining the wing-body zero-lift pitching-moment coefficient in the subsonic, transonic, and supersonic speed regimes. It is advisable to use experimental data whenever possible in each speed regime.

A. SUBSONIC

Two methods are presented for estimating the subsonic wing-body zero-lift pitching-moment coefficient for straight-tapered wings. Method 1 (Reference 1) was derived using the momentum considerations of H. Multhopp (Reference 2). Method 2 (Reference 3) has been empirically derived from fighter-type test data. Method 1 is considered to be more accurate than Method 2 because it includes the effects of fuselage width and fuselage camber distribution. Neither method is limited to bodies of revolution; however, only Method 1 accounts explicitly for noncircular bodies. If it becomes necessary to analyze a noncircular body in combination with a wing, the results of Method 2 should be used with caution.

DATCOM METHODS

Method 1

The wing-body zero-lift pitching-moment coefficient for straight-tapered wings* may be approximated by

$$\left(C_{m_0}\right)_{WB} = \left[\left(C_{m_0}\right)_W + \left(C_{m_0}\right)_B\right] \frac{\left(C_{m_0}\right)_M}{\left(C_{m_0}\right)_{M=0}} \qquad 4.3.2.1\text{-a}$$

where

$\left(C_{m_0}\right)_W$ is the wing zero-lift pitching-moment coefficient uncorrected for Mach-number effects, obtained from Section 4.1.4.1.

$\frac{\left(C_{m_0}\right)_M}{\left(C_{m_0}\right)_{M=0}}$ is the Mach-number correction factor obtained from Figure 4.1.4.1-6 as a function of Mach number. This chart gives the ratio of wing-body zero-lift pitching-moment coefficient in compressible flow to that in incompressible flow, based on test data.

$\left(C_{m_0}\right)_B$ is the body zero-lift pitching-moment coefficient, uncorrected for Mach-number effects. This parameter is approximated by using

$$\left(C_{m_0}\right)_B = \frac{(k_2 - k_1)}{36.5\, S_W \bar{c}} \sum_{x=0}^{x=\ell_B} w_f^2 \left[(\alpha_0)_W + (i_{CL})_B\right] \Delta x \qquad 4.3.2.1\text{-b}$$

*Method 1 should apply to non-straight-tapered planforms. However, the lack of a method for predicting the wing zero-lift pitching-moment contribution has prevented any substantiation of this method for non-straight-tapered planforms.

where

$(k_2 - k_1)$ is the apparent mass factor developed by Munk, obtained from Figure 4.2.1.1-20a as a function of the body fineness ratio

S_W is the wing reference area

$\bar{c}$ is the wing mean aerodynamic chord

w_f is the average width of a body increment (see Sketch (a))

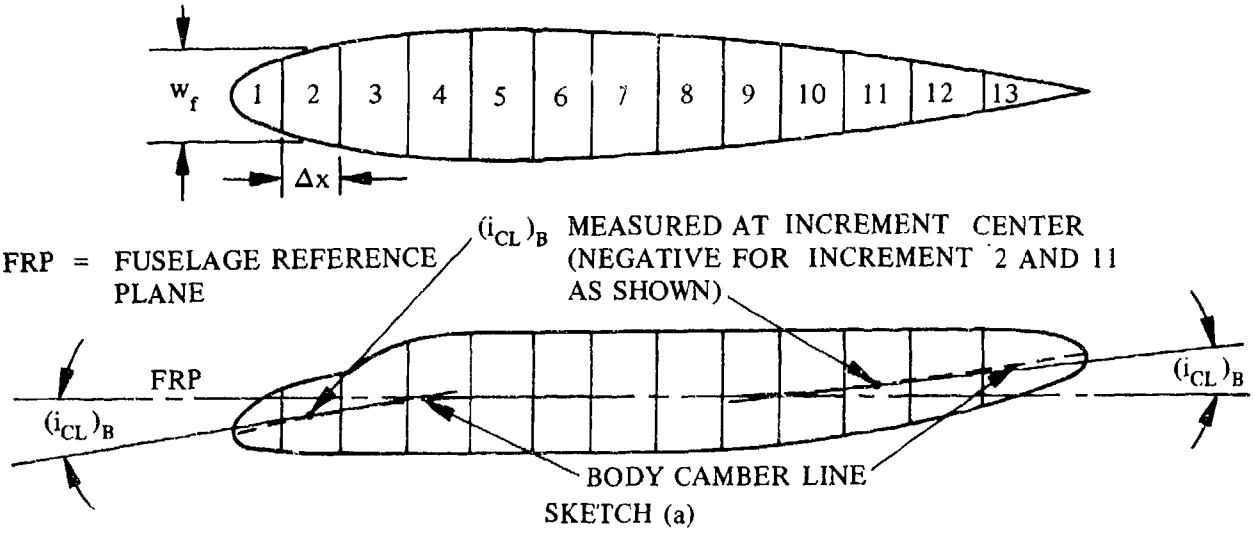
$(\alpha_0)_W$ is the wing zero-lift angle relative to the fuselage reference plane, obtained from test data or estimated by using the wing zero-lift angle-of-attack method of Section 4.1.3.1 (the effects of wing incidence must be considered when using the method of this section).

$(i_{CL})_B$ is the incidence angle of the fuselage camber line relative to the fuselage reference plane at the increment center. The sign convention of $(i_{CL})_B$ is identical to that of horizontal-tail incidence, and is negative for both nose droop and upsweep as shown in Sketch (a). The fuselage camber line is defined by the vertical location of the fuselage-maximum-width line or the body mean line where the maximum-width line is not clearly defined (see Sketch (b)).

Δx is the length of the body increment (see Sketch (a)). Fuselage increment length should be chosen so that neither the change in average width nor the change in camber line incidence is too large between successive increments. The increments need not be of equal length.

ℓ_B is the body length.

Equation 4.3.2.1-b may be evaluated by dividing the fuselage into increments (see Sketch (a)), computing the value of each increment, and adding them up.



SKETCH (a)

SEVERAL FUSELAGE CROSS-SECTIONS
SHOWING CAMBER LINE VERTICAL LOCATION

SKETCH (b)

A comparison of test data with results calculated by this method is presented in Table 4.3.2.1-A. It should be noted that the test data are for configurations having cambered airfoils. For most configurations with symmetrical wings with no twist, the predicted values are zero or very small.

Method 2

This method was developed in Reference 3 for fighter-type aircraft by using the linear regression analysis of mathematical statistics. In general, a regression analysis involves the study of a group of variables to determine their effect on a given parameter. Because of the empirical nature of this method (values for the regression coefficients), exact solutions are available only at the following Mach numbers: 0.4, 0.6, 0.7, 0.8, 0.9, 0.95, 1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 2.0, and 2.5. At other Mach numbers interpolation is necessary.

It is advisable to restrict the applicability of this method to the range of geometric parameters of the test data used in the formulation of the regression coefficients. The test data used in the formulation of the regression coefficients have geometric parameters within the following limits:

aspect ratio, A	1.6 to 6.0
taper ratio, λ	0 to 1
twist, θ	0 to -9.4^{o}
leading-edge radius, LER/$\bar{c}$	0 to 0.015
thickness, t/$\bar{c}$	0.025 to 0.10
NACA camber, $(y_c)_{max}/\bar{c}$	0 to 0.0263
conical-camber design lift coefficient, C_{L_d}	0 to 0.45
forebody fineness ratio, ℓ_N/d	2.2 to 8.4
afterbody fineness ratio, ℓ_A/d	0.3 to 5.6
leading-edge sweep, Λ_{LE}	0 to 70^{o}
Reynolds number, R_ℓ	0.8×10^6 to 8×10^6

This method is not limited to bodies of revolution; however, no attempt is made to account for the effects of noncircular bodies. If it becomes necessary to analyze a noncircular body in combination with a wing, it is suggested that an equivalent body of revolution be used, i.e., a body of revolution with the same cross-sectional area.

The wing-body zero-lift pitching-moment coefficient, based on the product of the wing area and mean aerodynamic chord $S_W \bar{c}_W$, is given at a specific Mach number by

$$\left(C_{m_0}\right)_{WB} = C_0 + C_1\left(\frac{1}{A}\right) + C_2\, A + C_3 \tan \Lambda_{LE} + C_4\left(\frac{t}{\bar{c}}\right) + C_5\left(\frac{\ell_N}{d}\right) + C_6\left(\frac{\ell_A}{d}\right) + C_7\, \lambda$$

$$+ C_8\, \lambda^2 + C_9\,(T_R) + C_{10}\left(\frac{LER}{\bar{c}}\right) + C_{11}\,\theta + C_{12}\left[\frac{\left(y_c\right)_{max}}{\bar{c}}\right] + C_{13}\, C_{L_d}$$

$$+ C_{14}\, W_L + C_{15}\, V_T + C_{16}\left(\frac{h}{d}\right) + C_{17}\left(\frac{\omega}{b}\right) + C_{18}\, R_\ell \qquad \text{4.3.2.1-c}$$

where

$C_0, C_1, \ldots C_{18}$ are the regression coefficients as a function of Mach number, obtained from Table 4.3.2.1-B.

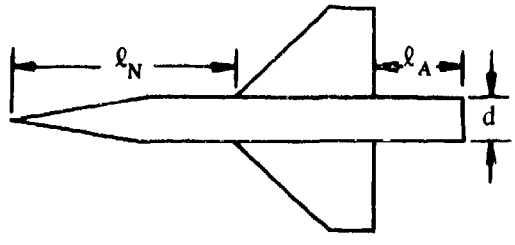
A is the total wing aspect ratio.

Λ_{LE} is the sweep of the leading edge.

$\frac{t}{c}$ is the wing thickness ratio at the mean aerodynamic chord.

$\frac{\ell_N}{d}$ is the nose and forebody fineness ratio (see Sketch (b)).

$\frac{\ell_A}{d}$ is the afterbody fineness ratio taken at the afterbody wing-body juncture (see Sketch (b)).



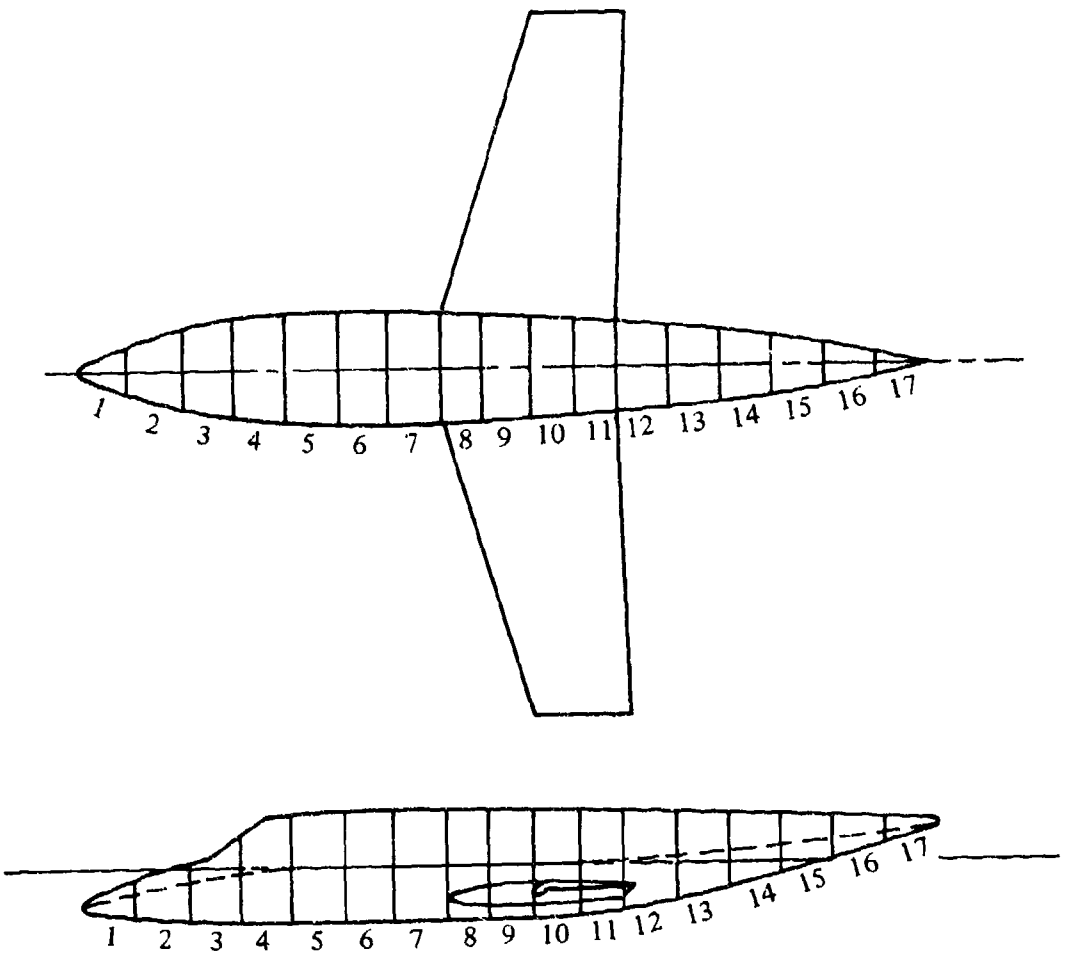
SKETCH (c)

λ	is the wing taper ratio.
T_R	is the transition indicator; 0 for no transition strips and 1 for transition strips or flight test.
$\frac{LER}{\bar{c}}$	is the ratio of the leading-edge radius to the mean aerodynamic chord taken at the mean aerodynamic chord.
θ	is the wing twist between the root and tip sections in radians, negative for washout (see Figure 5.1.2.1-30b).
$\frac{(y_c)_{max}}{\bar{c}}$	is the NACA camber in the form of a ratio of the maximum ordinate of the mean line to the airfoil chord taken at the mean aerodynamic chord.
C_{L_d}	is the conical-camber design lift coefficient for a M = 1.0 design with the designated camber ray line intersecting the wing trailing edge at 0.8 b/2. (For more details see Reference 4.) If the wing does not have a conical-camber design, the value of C_{L_d} is zero.
W_L	is the wing location index, with W_L = 1.0 for a high wing, W_L = 0.5 for a midwing, and W_L = 0 for a low wing.
V_T	is the vertical-tail indicator, with V_T = 1.0 for a vertical tail, and V_T = 0 for no vertical tail.
$\frac{h}{d}$	is the ratio of the maximum canopy height measured from the body center line to the body height at the point of maximum canopy height.
$\frac{d}{b}$	is the ratio of the maximum body width to wing span.
R_ℓ	is the Reynolds number based on the mean aerodynamic chord. For Reynolds numbers in excess of 8×10^6, the value of 8×10^6 should be used.

Sample Problems

1. Method 1

Given: The wing-body configuration of Reference 5 (Sketch (d))



SKETCH (d)

Wing Characteristics:

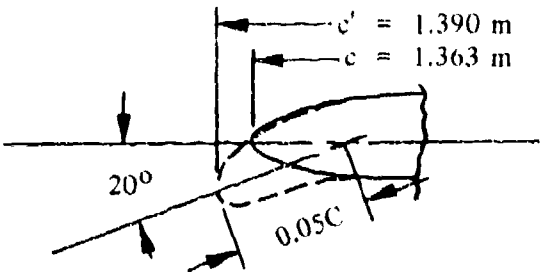
S_W = 21.51 m^2 $\bar{c}$ = 2.14 m θ = 0^o

A = 5.02 λ = 0.507 $\Lambda_{c/4}$ = 13^o

$(\alpha_0)_W$ = -1.2^o (test data) M = 0.17

Root section airfoil is a NACA 64A-109

Tip section airfoil is a NACA 64A-109 modified by drooping the leading edge (Sketch (e)).



SKETCH (e)

For the Tip Section

$c' = 1.390$ m $c = 1.363$ m $\delta_{f_{LE}} = 20^{o}$ $c_{f_{LE}} = 0.05c$

The drooped leading edge varies linearly across the span from the tip section as shown in Sketch (e), to zero extension and deflection at the root section.

Fuselage Characteristics:

$\ell_B = 12.50$ m $d_{max} = 1.62$ m

Other fuselage dimensions are measured from the three view drawings in Reference 5 and are listed in tabular form when used.

Compute:

Determine wing section c_{m_0}

Root Section (64A-109) c_{m_0} is determined through use of data from Table 4.1.1-B

SECTION	c_{m_0}
64A-010	0
64A-210	−0.040
64-108	−0.015
64-110	−0.020

Note that the variation in c_{m_0} due to camber is identical for the "64" and "64A" series airfoils, i.e., the 64A-210 airfoil has twice the camber of the 64-110 airfoil and twice the c_{m_0}. Therefore, the "64" series airfoil c_{m_0} values can be used to determine the thickness effects.

$$c_{m_{0_{64A\text{-}109}}} = \frac{c_{m_{0\,64\text{-}108}} + c_{m_{0_{64\text{-}110}}}}{2} = \frac{-0.015 - 0.020}{2} = -0.0175$$

Tip section c_{m_0} can be determined by the method of Section 6.1.2.1.

$$\frac{c_{f_{LE}}}{c'} = \left(\frac{c_{f_{LE}}}{c}\right)\frac{c}{c'} = 0.05 \quad \frac{(1.363)}{(1.390)} = 0.049$$

$$c'_{m_{\delta_{LE}}} = -0.00024 \qquad \text{(Figure 6.1.2.1-36)}$$

Since the wing is assumed to be at zero-lift, and drooped leading edges contribute essentially zero incremental lift at constant angle of attack, assume: $\Delta c_\ell = c_\ell = 0$.

$$\Delta c_{m_{LE}} = c'_{m_{\delta_{LE}}}\left(\frac{c'}{c}\right)\delta_{f_{LE}} + \left(\frac{x_{ref}}{c} + \frac{c' - c}{c}\right)\Delta c_\ell + c_m\left[\left(\frac{c'}{c}\right)^2 - 1\right]$$

$$+ 0.075\, c_\ell\left(\frac{c'}{c}\right)\left(\frac{c'}{c} - 1\right) \qquad \text{(Equation 6.1.2.1-b)}$$

$$= -0.00024\left(\frac{1.390}{1.363}\right)20 + 0 - 0.0175\left[\left(\frac{1.390}{1.363}\right)^2 - 1\right] + 0$$

$$\Delta c_{m_{LE}} = -0.0056$$

$$c_{m_{0_{TIP}}} = c_{m_{0_{\substack{BASIC\\AIRFOIL}}}} + \Delta c_{m_{LE}}$$

$$= -0.0175 - 0.0056$$

$$= -0.0231$$

Determine wing zero-lift pitching-moment coefficient using Section 4.1.4.1.

$$\left(C_{m_0}\right)_{\theta=0} = \frac{A\cos^2\Lambda_{c/4}}{A + 2\cos\Lambda_{c/4}}\left(\frac{c_{m_{0_{ROOT}}} + c_{m_{0_{TIP}}}}{2}\right) \qquad \text{(Equation 4.1.4.1-b)}$$

$$= \frac{5.02\cos^2(13^O)}{5.02 + 2\cos(13^O)}\left(\frac{-0.0175 - 0.0231}{2}\right)$$

$$= -0.0139$$

Determine the fuselage $(C_{m_0})_B$ using Equation 4.3.2.1-b and the three-view drawing in Reference 5. Divide the fuselage into incremental parts and compute the value under the summation sign for each increment (Sketch (d)).

INCREMENT	w_f (m)	$(\alpha_0)_W$ (DEG)	$(i_{CL})_B$ (DEG)	Δx (m)	$w_f^2 [(\alpha_0)_W + (i_{CL})_B] \Delta x$

15	0.735		−6.250		−3.051
16	0.485		−6.875		−1.440
17	0.175		−7.000		−0.190

$$\sum_{x=0}^{\ell_B} w_f^2 [(\alpha_0)_W + (i_{CL})_B] \Delta x = -75.373$$

Determine the apparent mass factor

$$\frac{\ell_B}{d_{max}} = \frac{12.50}{1.62} = 7.7$$

$(k_2 - k_1) = 0.905$ (Figure 4.2.1.1-20a)

Determine $(C_{m_0})_B$

$$\left(C_{m_0}\right)_B = \frac{(k_2 - k_1)}{36.5\, S_W \bar{c}} \sum_{x=0}^{x=\ell_B} w_f^2 [(\alpha_0)_W + (i_{CL})_B] \Delta x \qquad \text{(Equation 4.3.2.1-b)}$$

$$= \frac{0.905}{(36.5)(21.51)(2.14)} = (-75.373)$$

$$= -0.0406$$

$$\frac{\left(C_{m_0}\right)_M}{\left(C_{m_0}\right)_{M=0}} = 1.0 \text{ at } M = 0.17 \qquad \text{(Figure 4.1.4.1-6)}$$

Solution:

$$\left(C_{m_0}\right)_{WB} = \left[\left(C_{m_0}\right)_W + \left(C_{m_0}\right)_B\right] \frac{\left(C_{m_0}\right)_M}{\left(C_{m_0}\right)_{M=0}} \qquad \text{(Equation 4.3.2.1-a)}$$

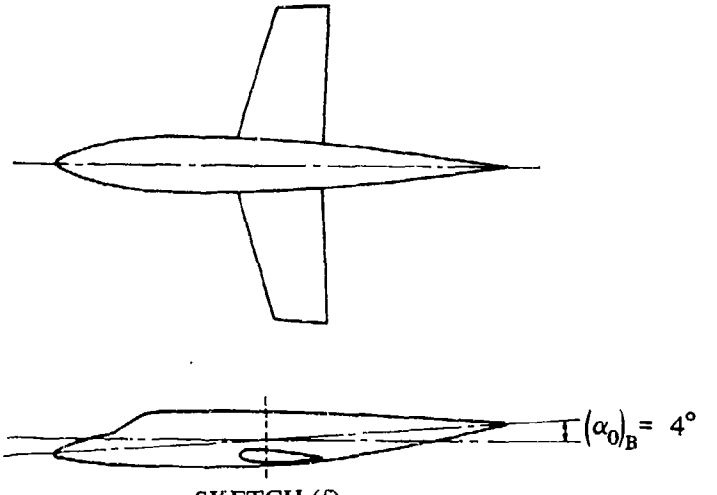
$$= (-0.0139 - 0.0406)\ 1.0$$

$$= -0.0545 \qquad \text{(based on } S_W \bar{c}\text{)}$$

This compares to a test value of −0.05 from Reference 5.

2. Method 2

Given: A wing-body configuration similar to that of Sample Problem 1 (See Sketch (f)).



SKETCH (f)

Wing Characteristics:

A = 5.0 $\quad \Lambda_{LE} = 15.6°$ $\quad \lambda = 0.5$ $\quad \theta = 0$

NACA 65-209 airfoil $\quad \frac{LER}{\bar{c}} = 0.00552$

$\frac{(y_c)_{max}}{\bar{c}} = 0.01071$ $\quad C_{L_d} = 0$ $\quad$ Low wing

Body Characteristics:

$\frac{\ell_N}{d} = 3.32$ $\quad \frac{\ell_A}{d} = 2.99$ $\quad \frac{h}{d} = 0.50$ $\quad \frac{d}{b} = 0.152$

Additional Characteristics:

M = 0.4 $\quad R_\ell = 6 \times 10^6$ $\quad$ No vertical tail $\quad T_R = 1$

Compute:

The regression coefficients below are obtained from Table 4.3.2.1-B at M = 0.4.

Regression Coefficient	Value Table 4.3.2.1-B
C_0	−0.61496
C_1	0.034113
C_2	−0.0043111
C_3	−0.0067607
C_4	0.58626
C_5	−0.0021631
C_6	−0.0029718
C_7	−0.0013161
C_8	0.0034451
C_9	−0.0097535
C_{10}	−3.9389
C_{11}	−0.52560
C_{12}	−4.3982
C_{13}	0.036116
C_{14}	0.034068
C_{15}	−0.073114
C_{16}	1.2683
C_{17}	−0.16503
C_{18}	$-0.00077192 \times 10^{-6}$

Solution:

$$\left(C_{m_0}\right)_{WB} = C_0 + C_1\left(\frac{1}{A}\right) + C_2\, A + C_3 \tan \Lambda_{LE} + C_4\left(\frac{t}{\bar{c}}\right) + C_5\left(\frac{\ell_N}{d}\right) + C_6\left(\frac{\ell_A}{d}\right)$$

$$+ C_7\, \lambda + C_8\, \lambda^2 + C_9\, (T_R) + C_{10}\left(\frac{LER}{\bar{c}}\right) + C_{11}\, \theta + C_{12}\left[\frac{\left(y_c\right)_{max}}{\bar{c}}\right]$$

$$+ C_{13}\, C_{L_d} + C_{14}\, W_L + C_{15}\, V_T + C_{16}\left(\frac{h}{d}\right) + C_{17}\left(\frac{d}{b}\right) + C_{18}\, R_\ell$$

(Equation 4.3.2.1-c)

$$\left(C_{m_0}\right)_{WB} = -0.61496 + \frac{0.034113}{5} - 0.0043111\,(5) - 0.0067607\,(0.2793)$$

$$+ 0.58626\,(0.09) - 0.0021631\,(3.32) - 0.0029718\,(2.99)$$

$$- 0.0013161\,(0.5) + 0.0034451\,(0.25) - 0.0097535\,(1)$$

$$- 3.9389\,(0.00552) - 0.5256\,(0) - 4.3982\,(0.01071) + 0.036116\,(0)$$

$$+ 0.034068\,(0) - 0.073114\,(0) + (1.2683)\,(0.5) - 0.16503\,(0.152)$$

$$- 0.00077192 \times 10^{-6}\,(6 \times 10^{6})$$

$$= -0.61496 + 0.0068226 - 0.021555 - 0.0018882 + 0.052763$$

$$- 0.0071815 - 0.0088857 - 0.00065805 + 0.00086128 - 0.0097535$$

$$- 0.021743 - 0.047105 + 0.63415 - 0.0250846 - 0.0046315$$

$$= -0.0688 \text{ (based on } S_W \bar{c}\ )$$

B. TRANSONIC

The comments and methods of Paragraph A are applicable here. It should be noted that at near-sonic conditions or whenever shocks begin appearing on the wing, the value of $(C_{m_0})_{WB}$ may begin to change abruptly. For this reason Method 1 should not be used above M = 0.9 and should be used judiciously for $0.8 \leqslant M \leqslant 0.9$. Likewise, Method 2 should be applied with caution at near-sonic conditions.

DATCOM METHODS

At transonic speeds the methods described in Paragraph A may be applied. (It should be noted for Method 1 that the subsonic method of Section 4.1.4.1 must be used to evaluate the wing zero-lift pitching-moment contribution.) Both methods are restricted to straight-tapered-wing configurations.

Sample Problems

No sample problems are presented here because their solutions would be obtained in the same manner as in the subsonic speed regime.

C. SUPERSONIC

In the supersonic speed regime Method 2 of Paragraph A of this section may be used to estimate $(C_{m_0})_{WB}$ for fighter-type aircraft. The comments in Paragraph A pertaining to Method 2 are applicable here.

DATCOM METHOD

At supersonic speeds Method 2 described in Paragraph A may be applied to fighter-type straight-tapered-wing configurations.

Sample Problem

No sample problem is presented here because its solution would be obtained in the same manner as in the subsonic speed regime.

4.3.2.2 WING-BODY PITCHING-MOMENT-CURVE SLOPE (AERODYNAMIC CENTER)

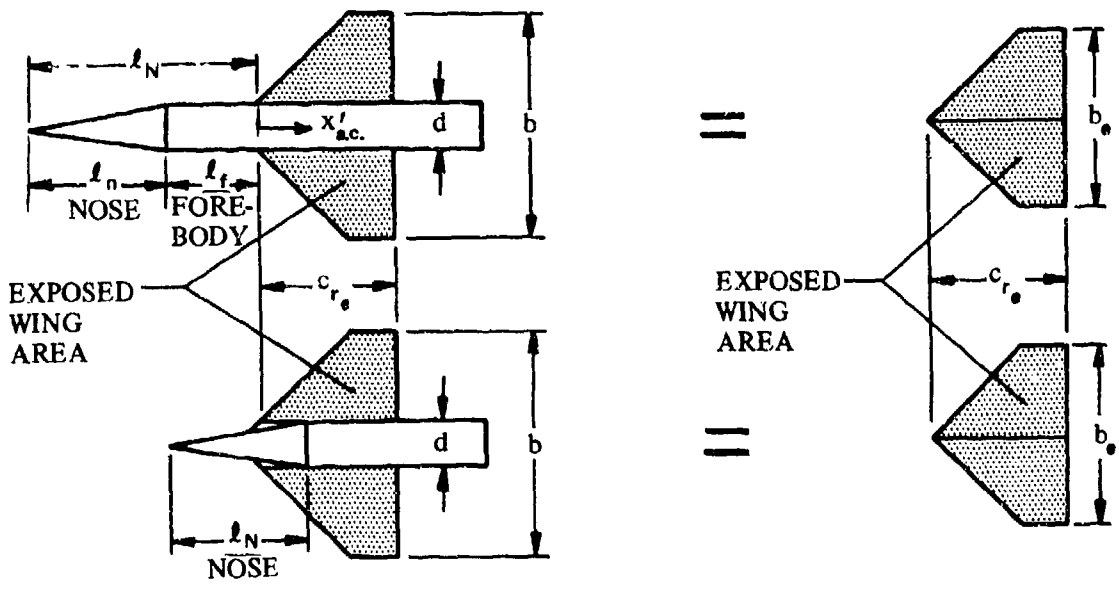
For wing-body configurations in which the body radii are large relative to the wing semispan, there exist mutual aerodynamic interferences between wing and body that can appreciably affect the aerodynamic center of the wing-body combination.

The body influences the wing lift primarily by inducing a change in the local angle of attack along the span. The wing influences the body by a lift carryover from the wing onto the body. For supersonic speeds the wing lift carryover on the body is displaced downstream parallel to the Mach lines, as illustrated in sketch (e) on page 4.3.1.2-5. Important moment differences can therefore exist between configurations in which the fuselage terminates at the wing trailing edge and those in which the fuselage extends beyond the wing trailing edge.

The aerodynamic-center location of a wing-body configuration is given in reference 1 as

$$\frac{x'_{a.c.}}{c_{r_e}} = \frac{\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N C_{L_{a_N}} + \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} C_{L_{a_{W(B)}}} + \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} C_{L_{a_{B(W)}}}}{C_{L_{a_N}} + C_{L_{a_{W(B)}}} + C_{L_{a_{B(W)}}}} \qquad 4.3.2.2\text{-a}$$

where the $x'_{a.c.}/c_{r_e}$ terms are the chordwise distances measured in exposed wing root chords from the apex of the exposed wing to the aerodynamic center, positive aft. The methods for calculating these terms are presented in this section and are based on exposed-wing geometry. The exposed wing is defined as the parts of the wing outboard of the largest body diameter at the wing-body intersection. Two cases are illustrated in sketch (a).



SKETCH (a)

The lift-curve slopes used in Equation 4.3.2.2-a are referred to the total wing area.

The aerodynamic-center location measured in wing root chords aft of the wing apex is given by

$$\frac{x_{a.c.}}{c_r} = \left(\frac{x'_{a.c.}}{c_{r_e}}\right) \frac{c_{r_e}}{c_r} + \frac{d}{2c_r} \tan \Lambda_{LE} \qquad 4.3.2.2\text{-b}$$

where $x'_{a.c.}/c_{r_e}$ is given by Equation 4.3.2.2-a.

The nose of the body is defined as the expanding portion of the body ahead of the wing. The forebody is the cylindrical portion of the body ahead of the wing. The base of the forebody is defined as the cross section at the wing-leading-edge – body intersection.

If the wing is at incidence relative to the body, the a.c. can be approximated by using the lift coefficient of each component – in the linear or near-linear range only – instead of the lift-curve slope. The angle of attack of the body relative to the free stream is used to calculate the body lift, and the angle of attack of the wing relative to the free stream is used to calculate the wing lift and lift carryover on the body.

The specific case of a conical body mounted on a delta wing (Sketch (c) on Page 4.3.1.2-2) has been solved by Spreiter in Reference 2. Slender-body theory is used to obtain the ratio of the wing-body lift to that of the wing alone. Correlation with experimental data by this method is good throughout the speed range. The method predicts that the aerodynamic center of the wing-body combination is the same as that of the wing alone.

Methods are presented in this section that are applicable to axisymmetric bodies in combination with straight-tapered wings throughout the subsonic, transonic, and supersonic speed ranges, and in combination with non-straight-tapered wings at subsonic and supersonic speeds. The methods are applicable only in the linear-lift range.

The effects of body cross-section shape and wing vertical position on wing-body lift-curve slope are not considered. (Some test data on these variables are given in References 3 and 4.) Therefore, the methods should not be construed as pertaining to generalized wing-body combinations with arbitrary body shapes.

The results of this section apply to single-wing-body configurations only; for cruciform and other multi-panel arrangements, interference effects may exist between the various panels.

The following general categories of non-straight-tapered wings are considered at subsonic and supersonic speeds:

Double-delta wings
Cranked wings
Curved (Gothic and ogee) wings

These wings are illustrated in Sketch (a) of Section 4.1.3.2. Their wing-geometry parameters are presented in Section 2.2.2.

A. SUBSONIC

DATCOM METHODS

Straight-Tapered Wing-Body Configurations

The subsonic aerodynamic-center location near zero lift of a wing-body configuration with a straight-tapered wing is obtained from the procedure outlined in the following steps:

Step 1. Divide the wing-body configuration into three components as follows and determine their pertinent geometric parameters (see Sketch (a)).

(1) The exposed wing in the presence of the body, denoted by the subscript W(B).

(2) The body in the presence of the wing, denoted by the subscript B(W).

(3) The body nose and forebody ahead of the wing-body juncture, denoted by the subscript N.

Step 2. Determine the lift-curve slope of the exposed wing $\left(C_{L_\alpha}\right)_e$ from the straight-tapered wing method of Paragraph A of Section 4.1.3.2, based on its exposed area S_e.

Step 3. Determine the lift-curve slope of the body nose by the method of paragraph A of Section 4.2.1.1. In most cases the slender-body-theory value of $\left(C_{N_\alpha}\right)_B = 2$ per radian (based on the nose frontal area) is sufficiently accurate.

Step 4. Using the lift-curve slopes determined in Steps 2 and 3, calculate $C_{L_{\alpha_{W(B)}}}$, $C_{L_{\alpha_{B(W)}}}$, and $C_{L_{\alpha_N}}$, referred to the total wing area, by

$$C_{L_{\alpha_{W(B)}}} = K_{W(B)} \left(C_{L_\alpha}\right)_e \frac{S_e}{S_W}$$

$$C_{L_{\alpha_{B(W)}}} = K_{B(W)} \left(C_{L_\alpha}\right)_e \frac{S_e}{S_W}$$

$$\left(C_{N_\alpha}\right)^*_N = \left(C_{N_\alpha}\right)_B \frac{\pi d^2}{4S_W}$$

where $K_{W(B)}$ and $K_{B(W)}$ are interference factors obtained from Figure 4.3.1.2-10.

Step 5. Determine the a.c. location of the exposed wing as a fraction of the root chord of the exposed wing $\frac{x'_{a.c.}}{c_{r_e}}$ from Figure 4.1.4.2-26. The interference effect of the body lift in the presence of the wing is neglected, and the a.c. location of the body-lift carryover on the wing is taken as the a.c. location for the exposed wing, i.e.,

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} = \frac{x'_{a.c.}}{c_{r_e}}$$

---

*The equation given for $\left(C_{N_\alpha}\right)_N$ is based on the slender-body-theory value for $\left(C_{N_\alpha}\right)_B$. If Equation 4.2.1.1-a is used to obtain $\left(C_{N_\alpha}\right)_B$, then $C_{N_{\alpha_N}} = \left(C_{N_\alpha}\right)_B \frac{(V_B)^{2/3}}{S_W}$

Step 6. Determine the a.c. location of the wing-lift carryover on the body $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$

For $\beta A_e \geq 4.0$, the a.c. contribution due to the lift carryover of the wing on the body is obtained from the equation

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} = \frac{1}{4} + \frac{b-d}{2c_{r_e}} \tan \Lambda_{c/4} \left[- \frac{k}{1-k} + \frac{\sqrt{1-2k}\ \log_e\left(\frac{1-k}{k} + \frac{1}{k}\sqrt{1-2k}\right) - (1-k) + \frac{\pi}{2}\ k}{\frac{k(1-k)}{\sqrt{1-2k}}\ \log_e\left(\frac{1-k}{k} + \frac{1}{k}\sqrt{1-2k}\right) + \frac{(1-k)^2}{k} - \frac{\pi}{2}\ (1-k)} \right] \qquad 4.3.2.2\text{-c}$$

where $k = d/b$ and the term inside the brackets is plotted for various values of k in Figure 4.3.2.2-35.

Equation 4.3.2.2-c is developed from lifting-line theory applied to the portion of a fictitious wing inside the body, defined by the image of the actual wing at the intersection of the wing quarter-chord line with the body. Equation 4.3.2.2-c is mathematically limited to $\frac{d}{b} \leq 0.5$, but extrapolation to $\frac{d}{b} = 0.8$ gives accurate results.

For $\beta A_e < 4.0$ an interpolation procedure is required. The a.c. location at $\beta A_e = 0$, derived from slender-body theory, is given in Figure 4.3.2.2-36b. For βA_e between 0 and 4.0, the a.c. of the wing-lift carryover on the body is obtained by fairing values between those obtained from Figure 4.3.2.2-36b and Equation 4.3.2.2-c for $\beta A_e = 0$ and $\beta A_e \geq 4.0$, respectively. It is recommended in Reference 1 that the interpolation procedure for $\beta A_e < 4.0$ be performed using the calculated wing-alone values $\left(\frac{d}{b} = 0\right)$ as a guide. However, for the purpose of the Datcom this calculation is omitted, and the fairing is performed between $\beta A_e = 0$ and $\beta A_e = 4.0$ by a curve through the value at $\beta A_e = 0$ and tangent to the calculated line for $\beta A_e \geq 4$.

Step 7. Determine the a.c. location of the body nose and forebody as a fraction of the root chord of the exposed wing $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N$, and referred to the exposed-wing apex.

Two methods are presented here for estimating the aerodynamic center of the nose and forebody (see Sketch (a)).

The first, which is based on the methods of Sections 4.2.1.1 and 4.2.2.1, is the more accurate of the two. It should be used when the nose lift is a significant fraction of the total lift of the vehicle. In Equation 4.2.2.1-b, ℓ_N should be substituted for x_m and dC_m/dC_L should be multiplied by the negative cube root of the nose volume and divided by c_{r_e}. This refers the moments to the apex of the exposed wing, i.e.,

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N = \left(C_{m_\alpha}\right)_{4.2.2.1} \left[- \frac{V_B^{1/3}}{c_{r_e}\left(C_{L_\alpha}\right)_{4.2.1.1}} \right]$$

The second method presented in this section gives more approximate answers than the first method. Figure 4.3.2.2-36a gives the aerodynamic-center location for cones, ogives, and ellipsoids without forebodies. For ogives with forebodies an approximation can be made by defining an equivalent ogive to replace the actual ogive and forebody. Thus

$$(f)_{equiv} = (f)_{nose} + 1.6\,(f)_{forebody} \qquad 4.3.2.2\text{-d}$$

where $(f)_{nose}$, $(f)_{forebody}$, and $(f)_{equiv}$ are the fineness ratios of the actual nose, the forebody, and the equivalent nose, respectively. Figure 4.3.2.2-36a is entered with the actual nose fineness ratio to obtain the a.c. of the equivalent nose, referred to the apex of the exposed wing. Then

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N = \left(\frac{x_{a.c.}}{\ell_{equiv}}\right)_N \left(\frac{\ell_{equiv}}{c_{r_e}}\right)$$

where ℓ_{equiv} is the length of the equivalent nose ($\ell_{equiv} = f_{equiv}\, d$).

Step 8. Using the results calculated in Steps 4 through 7, Equation 4.3.2.2-a gives the a.c. location of the wing-body configuration measured in exposed-wing root chords aft of the apex of the exposed wing. The a.c. location measured in wing root chords aft of the wing apex is given by Equation 4.3.2.2-b.

Application of this method is illustrated by the sample problem on Pages 4.3.2.2-7 through 4.3.2.2-10.

A comparison of test data with results calculated by using this method is presented as Table 4.3.2.2-A. The ranges of planform and flow parameters of the test data are:

$$2.88 \leq A \leq 4.0$$

$$7^\circ \leq \Lambda_{LE} \leq 60^\circ$$

$$0.143 \leq \lambda \leq 1.0$$

$$0.14 \leq d/b \leq 0.80$$

$$0.13 \leq M \leq 0.91$$

$$0.9 \times 10^6 \leq R_{\ell_{MAC}} \leq 6.8 \times 10^6$$

Although ranges of planform and flow parameters of the test data are in most cases quite broad, the limited number of test points makes it rather difficult to draw general conclusions regarding parameters not specifically noted in the prediction method. Within the linear-lift range, profile parameters such as camber, twist, and airfoil shape would be expected to have only a minor influence on the wing-body aerodynamic-center location. There are not enough data to allow a quantitative prediction of Reynolds-number effect, but it is reasonable to expect that Reynolds number will influence the wing-body aerodynamic-center location.

Non-Straight-Tapered Wing-Body Configuration

The method for determining the subsonic aerodynamic-center location near zero lift of wing-body configura-

tions with non-straight-tapered wings is taken fromReference 5. During the course of the study conducted in connection withReference 5, it was validated that the subsonic wing-body aerodynamic-center location of configurations with non-straight-tapered wings can be determined by using the wing-alone approach and neglecting the exposed-wing and body lift carryover and body-nose effects. Therefore, the method presented in paragraph A of Section 4.1.4.2 for determining the aerodynamic-center location of non-straight-tapered wings is directly applicable to the case of a body in combination with a non-straight-tapered wing.

Essentially, the method consists of dividing the complete theoretical wing planform (extended to the plane of symmetry) into two panels with each panel having conventional, straight-tapered geometry. Then for each of the constructed panels, the individual lift-curve slope and aerodynamic-center location are estimated by treating each constructed panel as a complete wing. The individual lift and aerodynamic-center location determined for each constructed panel are then mutually combined in accordance with an "inboard-outboard" weighted-area relationship to estimate the aerodynamic-center location for the basic wing-body configuration.

The sample problem of Paragraph A of Section 4.1.4.2 illustrates the use of the method.

Comparisons of test data with results calculated by using this wing-alone approach are presented as Tables 4.3.2.2-B and 4.3.2.2-C (both taken fromReference 5) for wing-body combinations with double-delta and cranked wings, respectively. Although the technique is applicable to wing-body combinations with curved wings, test data on such configurations are not available for substantiation purposes. Only two wing-body combinations with curved wings have been investigated. Since both of these configurations have very small bodies and the wing planform projection effectively blankets nearly all the body, they have been included in the curved wing-alone substantiation of Section 4.1.4.2 (Table 4.1.4.2-B). The ranges of planform parameters of the double-delta and cranked-wing configuration test data are:

Double-Delta Configurations	Cranked Configurations
$1.3 \leq A \leq 3.0$	$1.68 \leq A \leq 6.93$
$60^{\circ} \leq \Lambda_{LE_i} \leq 82.9^{\circ}$	$25^{\circ} \leq \Lambda_{LE_i} \leq 75^{\circ}$
$38.1^{\circ} \leq \Lambda_{LE_o} \leq 60^{\circ}$	$12^{\circ} \leq \Lambda_{LE_o} \leq 75^{\circ}$
$0.217 \leq \eta_B \leq 0.654$	$0.224 \leq \eta_B \leq 0.654$
$0 \leq \ell_N/\ell_B \leq 0.7$	$0 \leq \ell_N/\ell_B \leq 0.7$

The Mach-number range of the test data for the above configurations is $0.1 \leq M \leq 0.9$.

The test results indicate that airfoil shape, camber, and twist have only a minor influence on the wing-body aerodynamic-center location within the linear-lift range. There are not enough data to allow a quantitative prediction of Reynolds-number effect, but it is reasonable to expect that Reynolds number will influence the wing-body aerodynamic-center location.

Many double-delta and cranked wings have non-straight trailing edges with the trailing-edge break at a different span station from the leading-edge break. For such wings the irregular trailing-edge sweep angles of the subdivided panels are modified by using straight trailing-edge sweep angles for each panel, constructed so that the area moment about the respective wing-panel apex remains approximately the same

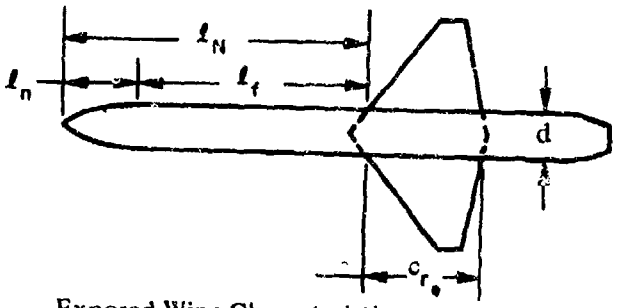
All the configurations listed inTables 4.3.2.2-B and 4.3.2.2-C have only one break in the wing leading edge. In certain cases, more than one wing leading-edge break can be handled provided the wing can be approximated by an equivalent two-panel planform. Such an approximation has been made for two cranked-wing

planforms included in the cranked-wing-alone data summary of Section 4.1.4.2 (Table 4.1.4.2-A). In both cases the inboard panel remains unchanged, and an outboard panel is approximated which has the same area moment about the wing-root apex as the original outer panels by adjusting and constructing straight leading and trailing edges.

Sample Problem

Straight-Tapered Wing Configuration

Given: A wing-body configuration ofReference 9.



Total-Wing Characteristics:

$A_W = 3.0$ $S_W = 250.56$ sq in. $\lambda_W = 0.143$

$\Lambda_{LE_W} = 38.7^o$ $\Lambda_{c/4_W} = 28.8^o$

$b_W = 27.4$ in. $c_{r_W} = 16.0$ in.

Exposed-Wing Characteristics:

$$A_e = 2.84 \quad \lambda_e = 0.169 \quad \Lambda_{LE_e} = \Lambda_{LE_W} = 38.7^o \quad \Lambda_{c/2_e} = 16.7^o$$

$$c_{r_e} = 13.5 \text{ in.} \quad \frac{S_e}{S_W} = 0.705$$

Body-Nose Characteristics:

Ogive-cylinder $d = 5.0$ in. $\dfrac{d}{b_W} = 0.183$

$\ell_n = 8.75$ in. $f_{nose} = \dfrac{\ell_n}{d} = 1.75$

$\ell_f = \ell_{forebody} = 26.65$ in. $f_{forebody} = \dfrac{\ell_f}{d} = 5.33$

Additional Characteristics:

$M = 0.60$; $\beta = 0.80$ $\kappa = 1.0$ (assumed)

Compute:

$\left(C_{L_\alpha}\right)_e$ (Section 4.1.3.2)

$$\frac{A_e}{\kappa}\left[\beta^2 + \tan^2 \Lambda_{c/2_e}\right]^{1/2} = 2.43$$

$$\left(\frac{C_{L_\alpha}}{A}\right)_e = 1.22 \text{ per rad} \quad \text{(Figure 4.1.3.2-49)}$$

$$\left(C_{L_\alpha}\right)_e = 3.46 \text{ per rad}$$

$\left(C_{N_\alpha}\right)_B$

$$\left(C_{N_\alpha}\right)_B = 2 \text{ per rad (based on nose frontal area) (slender-body theory)}$$

Interference factors (Section 4.3.1.2)

$$\left.\begin{aligned} K_{W(B)} &= 1.153 \\ K_{B(W)} &= 0.255 \end{aligned}\right\} \quad \text{(Figure 4.3.1.2-10 at } \frac{d}{b_W} = 0.183\text{)}$$

Component lift-curve slopes, referred to S_W

$$C_{L_{\alpha_{W(B)}}} = K_{W(B)} \left(C_{L_\alpha}\right)_e \frac{S_e}{S_W} = (1.153)(3.46)(0.705) = 2.81 \text{ per rad}$$

$$C_{L_{\alpha_{B(W)}}} = K_{B(W)} \left(C_{L_\alpha}\right)_e \frac{S_e}{S_W} = (0.255)(3.46)(0.705) = 0.622 \text{ per rad}$$

$$C_{L_{\alpha_N}} = \left(C_{N_\alpha}\right)_B \frac{\pi d^2}{4S_W} = (2.0) \frac{\pi (5.0)^2}{(4)(250.56)} = 0.1567 \text{ per rad}$$

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)}$ (Section 4.1.4.2)

$$\frac{\beta}{\tan \Lambda_{LE_e}} = \frac{0.80}{\tan 38.7^\circ} = 1.00$$

$$(A \tan \Lambda_{LE})_e = (2.84)(\tan 38.7^\circ) = 2.28$$

$$\frac{x'_{a.c.}}{c_{r_e}} = 0.440 \text{ (Figure 4.1.4.2-26a through -26c, interpolated for } \lambda_e\text{)}$$

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} = \frac{x'_{a.c.}}{c_{r_e}} = 0.440$$

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$

$\beta A_e = (0.80)(2.84) = 2.28$. Since $\beta A_e < 4.0$, an interpolation between values of $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$ at $\beta A_e = 0$ and $\beta A_e \geq 4.0$ must be performed. (See Step 6 of Datcom method.)

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$ at $\beta A_e = 0$

$$\frac{1}{4} A_e (1 + \lambda_e) \tan\Lambda_{LE} = \frac{1}{4} (2.84)(1.169)(\tan 38.7^{\circ}) = 0.665$$

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} = 0.330 \text{ (Figure 4.3.2.2-36b)}$$

$\left(\frac{x'_{a.c}}{c_{r_e}}\right)_{B(W)}$ at $\beta A_e \geq 4.0$

$$k = \frac{d}{b_W} = 0.183;\ 1 - k = 0.817;\ \sqrt{1 - 2k} = 0.796$$

$$\log_e \left(\frac{1-k}{k} + \frac{1}{k}\sqrt{1 - 2k}\right) = 2.176$$

Evaluate the term in brackets of Equation 4.3.2.2-c

$$\left[-\frac{k}{1-k} + \frac{\frac{b}{2}\sqrt{1-2k}\log_e\left(\frac{1-k}{k} + \frac{1}{k}\sqrt{1-2k}\right) - \frac{b}{2}(1-k) + \frac{\pi b}{4}k}{\frac{b}{2}\frac{k(1-k)}{\sqrt{1-2k}}\log_e\left(\frac{1-k}{k} + \frac{1}{k}\sqrt{1-2k}\right) + \frac{b}{2}\frac{(1-k)^2}{k} - \frac{\pi b}{4}(1-k)} \right] =$$

$$\left[-\frac{0.183}{0.817} + \frac{13.7\ (0.796)(2.176) - 13.7\ (0.817) + \frac{\pi}{2}(13.7)(0.133)}{\frac{13.7\ (0.183)(0.817)(2.176)}{0.796} + 13.7\ \frac{(0.817)^2}{0.183} - \frac{\pi}{2}(13.7)(0.817)} \right] = 0.210$$

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} = \frac{1}{4} + \frac{b - d}{2 c_{r_e}} \tan \Lambda_{c/4} \quad [0.210] \quad \text{(Equation 4.3.2.2-c)}$$

$$= \frac{1}{4} + \frac{27.4 - 5}{2(13.5)} (0.5498)\ [0.210]$$

$$= 0.346$$

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} = 0.345 \text{ (interpolated using values at } \beta A_e = 0 \text{ and } \beta A_e \geq 4.0)$$

(See Step 6 of the Datcom method for the interpolation procedure.)

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N$$

$(f)_{equiv} = (f)_{nose} + 1.6\,(f)_{forebody}$ (Equation 4.3.2.2-d)

$= 1.75 + 1.6\,(5.33) = 10.28$

$\ell_{equiv} = (f_{equiv})\,(d) = (10.28)\,(5) = 51.4$

$\left(\frac{x_{a.c.}}{\ell_{equiv}}\right)_N = -0.545$ (Figure 4.3.2.2-36a at f_{nose})

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N = \left(\frac{x_{a.c.}}{\ell_{equiv}}\right)\left(\frac{\ell_{equiv}}{c_{r_e}}\right) = (-0.545)\ \frac{51.4}{13.5} = -2.075$$

Solution:

$$\frac{x'_{a.c.}}{c_{r_e}} = \frac{\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N C_{L_{a_N}} + \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} C_{L_{a_{W(B)}}} + \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} C_{L_{a_{B(W)}}}}{C_{L_{a_N}} + C_{L_{a_{W(B)}}} + C_{L_{a_{B(W)}}}}$$ (Equation 4.3.2.2-a)

$$= \frac{(-2.075)\,(0.1567) + (0.440)\,(2.81) + (0.345)\,(0.622)}{0.1567 + 2.81 + 0.622}$$

$= 0.313$

$$\frac{x_{a.c.}}{c_r} = \left(\frac{x'_{a.c.}}{c_{r_e}}\right)\frac{c_{r_e}}{c_r} + \frac{d}{2\,c_r}\tan\Lambda_{LE}$$ (Equation 4.3.2.2-b)

$$= (0.313)\ \frac{13.5}{16.0} + \frac{5}{2\,(16)}\,(0.8012)$$

$= 0.389$

The calculated result compares with a test value of $\frac{x_{a.c.}}{c_r} = 0.35$ from Reference 9.

B. TRANSONIC

DATCOM METHOD

The transonic aerodynamic-center location near zero lift of a wing-body configuration with a straight-tapered wing may be approximated by the wing-body-combination approach presented in Paragraph A. In using this method at transonic speeds, care must be taken to evaluate the parameters by using the transonic methods presented in the applicable Datcom sections. The estimation of both the lift-curve slope and the aerodynamic-center location of the exposed wing at transonic speeds requires the use of data-fairing techniques outlined in Paragraphs B of Sections 4.1.3.2 and 4.1.4.2, respectively. It is suggested that the aerodynamic-center location of the wing lift carryover on the body $\left(x'_{a.c.}/c_{r_e}\right)_{B(W)}$ be estimated by the methods of Paragraphs A and C of this section, and any differences in the subsonic and supersonic values should be faired out smoothly in the transonic range. The two methods presented for estimating the aerodynamic-center location of the nose and forebody $\left(x'_{a.c.}/c_{r_e}\right)_N$ in Paragraph A of this section may be applied at transonic speeds.

The relatively simple application of the body effects on the aerodynamic-center location at transonic speeds is based on slender-body theory, which states that body force and moment characteristics are not functions of Mach number. On the other hand, the aerodynamic characteristics of wings in the transonic speed range are quite complex, and theoretical solutions are available for only a few specific planforms. Wing lift and pitching-moment characteristics at transonic speeds are discussed in Sections 4.1.3.2 and 4.1.4.2, respectively, and are not repeated here. The transonic methods of Sections 4.1.3.2 and 4.1.4.2 are applicable only to wings having symmetrical airfoils of conventional thickness distribution at low angles of attack.

C. SUPERSONIC

DATCOM METHODS

Straight-Tapered Wing-Body Configuration

The supersonic aerodynamic-center location near zero lift of a wing-body configuration with a straight-tapered wing is obtained by the wing-body-combination approach presented in Paragraph A. The procedure, applied at supersonic speeds, is outlined in the following steps:

Step 1. Divide the wing-body configuration into three components as in Step 1 of Paragraph A.

Step 2. Determine the normal-force-curve slope of the exposed wing $\left(C_{N_\alpha}\right)_e$ from the straight-tapered-wing method of Paragraph C of Section 4.1.3.2, based on its exposed area S_e.

Step 3. Determine the normal-force-curve slope of the body nose $\left(C_{N_\alpha}\right)_B$ by the method of Paragraph C of Section 4.2.1.1, based on the nose frontal area.

Step 4. Using the normal-force-curve slopes determined in Steps 2 and 3, calculate $C_{N_{\alpha_{W(B)}}}$, $C_{N_{\alpha_{B(W)}}}$, and $C_{N_{\alpha_N}}$, referred to the total wing area, by

$$C_{N_{\alpha_{W(B)}}} = K_{W(B)} \left(C_{N_\alpha}\right)_e \frac{S_e}{S_W}$$

$$C_{N_{\alpha_{B(W)}}} = K_{B(W)} \left(C_{N_\alpha}\right)_e \frac{S_e}{S_W}$$

$$C_{N_{\alpha_N}} = \left(C_{N_\alpha}\right)_B \frac{\pi d^2}{4S_W}$$

where $K_{W(B)}$ and $K_{B(W)}$ are interference factors obtained from Paragraph C of Section 4.3.1.2.

Step 5. Determine the a.c. location of the exposed wing as a fraction of the root chord of the exposed wing $\frac{x'_{a.c.}}{c_{r_e}}$ from Figure 4.1.4.2-26. The interference effect of the body-lift in the presence of the wing is neglected and the a.c. location of the body-lift carryover on the wing is taken as the a.c. location for the exposed wing, i.e.,

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} = \frac{x'_{a.c.}}{c_{r_e}}$$

Step 6. Determine the a.c. location of the wing-lift carryover on the body $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$

Figure 4.3.2.2-37 is presented for estimating the a.c. of the lift carryover of the wing onto the body. The result is referred to the leading edge of the root chord of the exposed wing. Figure 4.3.2.2-37 is valid for

$$\beta A_e \ (1 + \lambda_e) \left(1 + \frac{1}{\beta \cot \Lambda_{LE}}\right) \geq 4.0$$

Figure 4.3.2.2-37 can be used for an approximation to $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$ for the low-aspect-ratio range. However, if a more accurate result is desired, the low-aspect-ratio values may be found by cross-plotting these charts and extrapolating them to the slender-body-theory values at $\beta A_e = 0$ from Figure 4.3.2.2-36b.

Step 7. Determine the a.c. location of the body nose and forebody as a fraction of the root chord of the exposed wing $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N$, and referred to the exposed-wing apex.

The center of pressure of the body nose and forebody as a fraction of body-nose length $\frac{x_{c.p.}}{\ell_N}$, and referred to the nose apex is obtained from Paragraph C of Section 4.2.2.1. Then

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N = \frac{\ell_N}{c_{r_e}} \left(\frac{x_{c.p.}}{\ell_N} - 1\right)$$

Step 8. Using the results calculated in Steps 4 through 7, Equation 4.3.2.2-a gives the a.c. location of the wing-body configuration measured in exposed wing root chords and aft of the exposed wing apex. The a.c. location measured in wing root chords aft of the wing apex is given by Equation 4.3.2.2-b.

Sample Problem 1 on Pages 4.3.2.2-18 through 4.3.2.2-21 illustrates the use of this method.

A comparison of test data with results calculated by using this method is presented as Table 4.3.2.2-D. The limited number of test points presented precludes substantiation of this method over other than very limited ranges of planform and flow parameters. Within the linear-lift range, profile parameters such as camber, twist, and airfoil shape would be expected to have only a minor influence on the wing-body aerodynamic-center location.

It should be noted that the Datcom method for configurations with non-straight-tapered wings, which follows, uses essentially the same approach as that presented for configurations with straight-tapered wings. Therefore, substantiation of the method for non-straight-tapered wings serves to validate the method for straight-tapered wings.

Non-Straight-Tapered Wing-Body Configurations

The method for determining the supersonic aerodynamic-center location near zero lift of wing-body configurations with non-straight-tapered wings is taken from Reference 5. Both the wing-alone and the wing-body a.c.-prediction approaches are applied at supersonic speeds. Criteria have been established, during the course of the study conducted in connection with Reference 5, for determining which prediction approach is applicable to a given configuration.

The wing-body combinations are treated as wing-alone cases when the theoretical wing planform practically blankets the body. For such cases, the Datcom method for predicting the aerodynamic-center location of non-straight-tapered wings presented in Paragraph C of Section 4.1.4.2 is directly applicable. The method consists of dividing the complete theoretical planform (extended to the plane of symmetry) into two panels with each panel having conventional, straight-tapered geometry. Then for each of the constructed panels, the individual normal-force-curve slope and aerodynamic-center location are estimated by treating each constructed panel as a complete wing. The individual normal-force-curve slope and aerodynamic-center location determined for each constructed panel are then mutually combined in accordance with an "inboard-outboard" weighted-area relationship to estimate the aerodynamic-center location for the basic wing-body configuration.

The sample problem at the conclusion of Paragraph C of Section 4.1.4.2 illustrates the wing-alone approach.

The majority of the wing-body combinations investigated in Reference 5 required application of the wing-body approach to predict the linear aerodynamic-center location. This approach, introduced in this section, consists of breaking down the wing-body configuration into components and evaluating the exposed-wing lift in the presence of the body, the wing-lift carryover on the body, and the body nose effects. The basic approach is then essentially that presented for predicting the aerodynamic-center location of straight-tapered wing-body configurations at supersonic speeds. However, the method is more complex, since the exposed composite wing must be subdivided in order to estimate its normal-force-curve slope and aerodynamic-center location.

The procedure to be followed in using the wing-body approach to predict the supersonic linear aerodynamic-center location of a non-straight-tapered wing-body combination is outlined in the following steps:

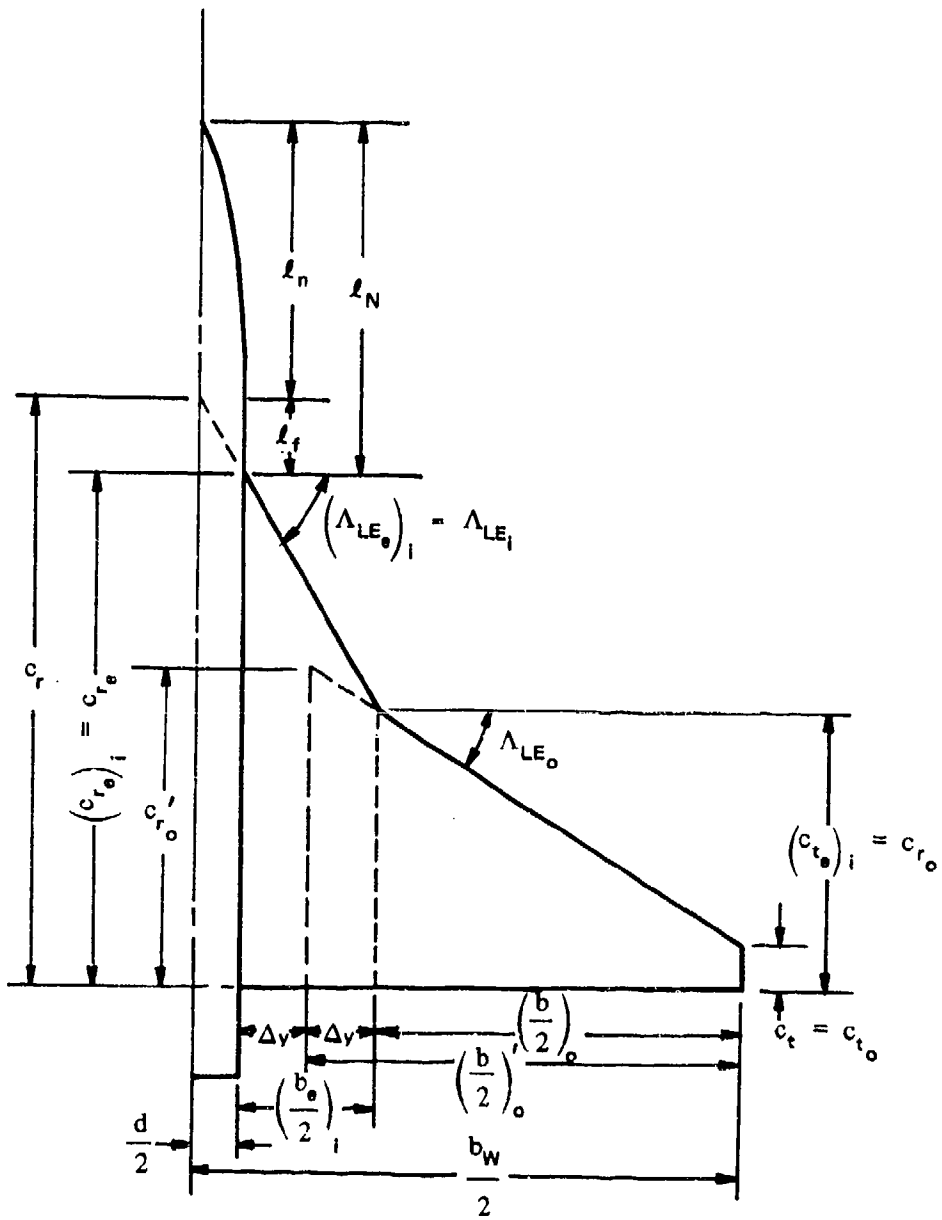
Step 1. Divide the wing-body configuration into three components as follows (see Sketch (a)):

(1) The exposed composite wing in the presence of the body, denoted by the subscript W(B).

(2) The body in the presence of the wing, denoted by the subscript B(W).

(3) The body nose and forebody ahead of the wing-body juncture, denoted by the subscript N.

Step 2. Subdivide the exposed composite wing into inboard and outboard panels and determine their pertinent geometric parameters. The exposed wing is subdivided as discussed and illustrated in Paragraph A of Section 4.1.4.2 (see Pages 4.1.4.2-4 through 4.1.4.2-6). Application of that technique applied to a typical wing-body configuration is illustrated in Sketch (b).



SKETCH (b)

Step 3. Determine the normal-force-curve slope $\left[\left(C_{N_\alpha}\right)_e\right]_i$ of the constructed inboard panel using the method for straight-tapered wings of Paragraph C, Section 4.1.3.2, based on the area $(S_e)_i$.

Step 4. Determine the a.c. location of the constructed inboard panel $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_i$ as a fraction of its root chord from Figure 4.1.4.2-26. This a.c. location is aft of the apex of the exposed constructed inboard panel.

Step 5. Determine the normal-force-curve slope $\left(C_{N_\alpha}\right)_o'$ of the constructed outboard panel using the method for the straight-tapered wings of Paragraph C of Section 4.1.3.2, based on the area S_o'.

Step 6. Determine the a.c. location of the constructed outboard panel $\left(\frac{x_{a.c.}}{c_r}\right)_o'$ as a fraction of its root chord from Figure 4.1.4.2-26. This a.c. location is aft of the apex of the constructed outboard panel.

Step 7. Convert the a.c. location determined in Step 6 to a fraction of the root chord of the exposed constructed inboard panel and aft of the apex of the exposed constructed inboard panel by

$$\frac{(x'_{a.c.})'_o}{(c_{r_e})_i} = \left(\frac{x_{a.c.}}{c_r}\right)'_o \frac{c'_{r_o}}{(c_{r_e})_i} - \frac{\Delta y}{(c_{r_e})_i} \tan \Lambda_{LE_o} + \frac{(b_e)_i}{2(c_{r_e})_i} \tan \Lambda_{LE_i} \qquad 4.3.2.2\text{-e}$$

Step 8. Calculate the a.c. location for the exposed composite wing, measured in root chords of the exposed inboard panel, aft of the exposed composite-wing apex by

$$\frac{x'_{a.c.}}{c_{r_e}} = \frac{\left[\left(C_{N_\alpha}\right)_e\right]_i (S_e)_i \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_i + \left(C_{N_\alpha}\right)'_o S'_o \frac{(x'_{a.c.})'_o}{(c_{r_e})_i}}{\left[\left(C_{N_\alpha}\right)_e\right]_i (S_e)_i + \left(C_{N_\alpha}\right)'_o S'_o} \qquad 4.3.2.2\text{-f}$$

Step 9. Calculate the normal-force-curve slope for the exposed composite wing, based on the exposed wing area, by

$$\left(C_{N_\alpha}\right)_e = \frac{\left[\left(C_{N_\alpha}\right)_e\right]_i (S_e)_i + \left(C_{N_\alpha}\right)'_o S'_o}{(S_e)_i + S'_o} \qquad 4.3.2.2\text{-g}$$

Step 10. Determine the normal-force-curve slope of the body nose $\left(C_{N_\alpha}\right)_B$ by the method of Paragraph C of Section 4.2.1.1, based on the nose frontal area.

Step 11. Using the normal-force-curve slopes determined in Steps 9 and 10, calculate $C_{N_{\alpha_{W(B)}}}$, $C_{N_{\alpha_{B(W)}}}$, and $C_{N_{\alpha_N}}$, referred to the total wing area, by

$$C_{N_{a_{W(B)}}} = K_{W(B)} \left(C_{N_a}\right)_e \frac{(S_e)_i + S'_o}{S_W}$$

$$C_{N_{a_{B(W)}}} = K_{B(W)} \left(C_{N_a}\right)_e \frac{(S_e)_i + S'_o}{S_W}$$

$$C_{N_{a_N}} = \left(C_{N_a}\right)_B \frac{\pi d^2}{4S_W}$$

where $K_{W(B)}$ and $K_{B(W)}$ are interference factors obtained from Paragraph C of Section 4.3.1.2. The design charts of Section 4.3.1.2 are entered with the following geometric parameters:

A_e is the aspect ratio of the exposed composite wing.

λ_e is the taper ratio of the exposed composite wing $c_t/\left(c_{r_e}\right)_i$

Λ_{LE} is replaced by Λ_{LE_i}.

b is the total wing span (to body center line).

c_{r_e} is replaced by $\left(c_{r_e}\right)_i$.

Step 12. Determine the a.c. location of the exposed wing in the presence of the body $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)}$. Th interference effect of the body lift in the presence of the wing is neglected and

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} = \frac{x'_{a.c.}}{c_{r_e}} \text{ (from Step 8)}$$

Step 13. Determine the a.c. location of the wing-lift carryover on the body $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$ by the procedure outlined in Step 6 of the supersonic Datcom method for determining $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$ for a straight-tapered wing-body configuration (Page 4.3.2.2-12). In applying that procedure the geometric parameters to be used are those defined in Step 11 of this method (see above).

Step 14. Determine the a.c. location of the body nose as a fraction of the root chord of the exposed wing $\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N$, and referred to the exposed-wing apex, by the procedure outlined in Step 7 of the Datcom method for a straight-tapered wing-body configuration (Page 4.3.2.2-12).

Step 15. Using the results calculated in Steps 11 through 14, Equation 4.3.2.2-a gives the a.c. location of the wing-body configuration measured in root chords of the exposed composite wing and aft of the apex of the exposed composite wing. The a.c. location, measured in root chords of the composite wing and aft of the wing apex, is given by Equation 4.3.2.2-b. In applying Equation 4.3.2.2-b the leading-edge sweep angle is that of the inboard panel Λ_{LE_i}.

This method is illustrated by Sample Problem 2 on Pages 4.3.2.2-21 through 4.3.2.2-26.

Comparisons of test data with results calculated by using this method are presented in Tables 4.3.2.2-E and 4.3.2.2-F (both taken from Reference 5) for configurations with double-delta and cranked wings, respectively The test data indicate that within the linear-lift range, profile parameters such as camber, twist, and airfoil shape have only a minor effect on the wing-body aerodynamic-center location. The ranges of planform parameters of the test data are:

Double-Delta Configurations	Cranked Configurations
$1.3 \leqslant A \leqslant 3.0$	$1.88 \leqslant A \leqslant 4.60$
$0 \leqslant \lambda \leqslant 0.143$	$0.086 \leqslant \lambda \leqslant 0.333$
$0.217 \leqslant \eta_B \leqslant 0.710$	$0.400 \leqslant \eta_B \leqslant 0.700$
$60^o \leqslant \Lambda_{LE_i} \leqslant 82.9^o$	$60^o \leqslant \Lambda_{LE_i} \leqslant 70.7^o$
$35^o \leqslant \Lambda_{LE_o} \leqslant 60^o$	$35^o \leqslant \Lambda_{LE_o} \leqslant 75^o$

The range of Mach number for both of these configurations is $1.0 \leqslant M \leqslant 3.0$.

The test configurations investigated have only one break in the leading-edge sweep, and for those configurations with both leading- and trailing-edge breaks, both breaks occur at the same span station.

Three double-delta configurations of Table 4.3.2.2-E meet the criteria established for the wing-alone prediction technique. Satisfactory results were obtained for each of these configurations by using the wing-alone approach. These cases are noted in Table 4.3.2.2-E. All the cranked-wing test configurations of Table 4.3.2.2-F were analyzed by using the wing-body approach.

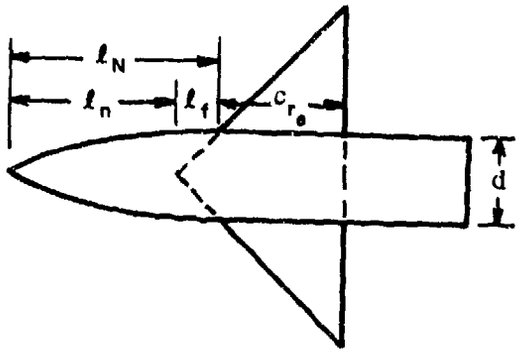
It should be noted that several configurations which meet the prediction criteria for the wing- body approach have been evaluated by using the wing-alone approach, in which the wing-lift carryover and body-nose effects are neglected. The wing-alone approach did not yield satisfactory predictions for any of those configurations.

Although the techniques are applicable to wing-body combinations with curved wings, test data are not available for substantiation purposes. Only one wing-body combination with a curved wing has been investigated at supersonic speeds. Since this configuration has a very small body and the planform projection effectively blankets nearly all the body, it has been included in the curved wing alone substantiation of Section 4.1.4.2 (Table 4.1.4.2-C).

Sample Problems

1. Straight-Tapered Wing-Body Configuration

Given: A wing-body configuration of Reference 26.



Total-Wing Characteristics:

$A_W = 4.0 \quad S_W = 13.99$ sq in. $\quad \lambda_W = 0$

$\Lambda_{LE_W} = 45^o \quad b_W = 7.48$ in.

$c_{r_W} = 3.74$ in.

Airfoil: 8-percent-thick double wedge (free-stream direction)

Exposed-Wing Characteristics:

$$A_e = 4.0 \quad \lambda_e = 0 \quad \Lambda_{LE_e} = \Lambda_{LE_W} = 45^o$$

$$c_{r_e} = 3.0 \text{ in.} \quad \frac{S_e}{S_W} = 0.64$$

Body-Nose Characteristics:

Ogive-cylinder $\quad d = 1.50$in. $\quad \dfrac{d}{b_W} = 0.20 \quad \ell_N = 5.0$ in.

$$\ell_n = 4.25 \text{ in.} \quad f_{nose} = \frac{\ell_n}{d} = 2.83$$

$$\ell_f = \ell_{forebody} = 0.75 \text{ in.} \quad f_{forebody} = \frac{\ell_f}{d} = 0.50$$

Additional Characteristics:

$M = 1.50$; $\beta = 1.12$

Compute:

$\left(C_{N_\alpha}\right)_e$ (Section 4.1.3.2)

$$\frac{\tan \Lambda_{LE}}{\beta} = \frac{1.00}{1.12} = 0.893 \text{ ; } A_e \tan \Lambda_{LE} = (4.0)(1.00) = 4.00$$

$$\beta \left[\left(C_{N_\alpha}\right)_{theory}\right]_e = 4.0 \text{ per rad (Figure 4.1.3.2-56a)}$$

$$\left[\left(C_{N_\alpha}\right)_{\text{theory}}\right]_e = 4.0/1.12 = 3.57 \text{ per rad}$$

$$\delta_\perp = \frac{\tan^{-1}\ \frac{0.04}{0.50}}{\cos \Lambda_{LE}} = 6.48^\circ$$

$$\left[\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{\text{theory}}}\right]_e = 0.884 \text{ (Figure 4.1.3.2-60)}$$

$$\left(C_{N_\alpha}\right)_e = \left[\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{\text{theory}}}\right]_e \left[\left(C_{N_\alpha}\right)_{\text{theory}}\right]_e = 0.884\ (3.57) = 3.16 \text{ per rad}$$

$\left(C_{N_\alpha}\right)_B$ (Section 4.2.1.1)

$$\frac{\beta}{f_n} = \frac{1.12}{2.83} = 0.396\ ;\ \frac{f_f}{f_n} = \frac{0.50}{2.83} = 0.177$$

$\left(C_{N_\alpha}\right)_B = 2.60$ per rad (based on nose frontal area) (Figure 4.2.1.1-21a)

Interference factors (Section 4.3.1.2)

$K_{W(B)} = 1.17$ (Figure 4.3.1.2-10 at $\frac{d}{b_W} = 0.20$)

$K_{B(W)}$ (Figure 4.3.1.2-11a)

$$\frac{\beta d}{c_{r_e}} = \frac{(1.12)\ (1.50)}{3.0} = 0.560\ ;\ \beta \cot \Lambda_{LE} = (1.12)\ (1.00) = 1.12$$

$$\left[\beta \left(C_{N_\alpha}\right)_e\ (\lambda_e + 1)\ \left(\frac{b}{d} - 1\right)\right] = 1.12\ (3.16)\ (1.0)\ (4.0) = 14.16$$

$$K_{B(W)} \left[\beta \left(C_{N_\alpha}\right)_e\ (\lambda_e + 1)\ \left(\frac{b}{d} - 1\right)\right] = 3.60 \text{ (Figure 4.3.1.2-11a)}$$

$$K_{B(W)} = 3.60/14.16 = 0.254$$

Component normal-force-curve slopes, referred to S_W

$$C_{N_{\alpha_{W(B)}}} = K_{W(B)}\ \left(C_{N_\alpha}\right)_e\ \frac{S_e}{S_W} = 1.17\ (3.16)\ (0.64) = 2.37 \text{ per rad}$$

$$C_{N_{\alpha_{B(W)}}} = K_{B(W)} \left(C_{N_\alpha}\right)_B \frac{S_e}{S_W} = 0.254\ (3.16)\ (0.64) = 0.514 \text{ per rad}$$

$$C_{N_{\alpha_N}} = \left(C_{N_\alpha}\right)_B \frac{\pi d^2}{4S_W} = 2.60\ \frac{\pi(1.5)^2}{4(13.99)} = 0.328 \text{ per rad}$$

$\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_{W(B)}$ (Section 4.1.4.2)

$\frac{X'_{a.c.}}{c_{r_e}} = 0.670$ (Figure 4.1.4.2-26a)

$$\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_{W(B)} = \frac{X'_{a.c.}}{c_{r_e}} = 0.670$$

$\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_{B(W)}$

$$\beta A_e\ (1 + \lambda_e) \left(1 + \frac{1}{\beta \cot \Lambda_{LE}}\right) = (1.12)\ (4.0)\ (1.0) \left(1 + \frac{1}{1.12}\right) = 8.48;\ > 4.0.$$

$\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_{B(W)} = 0.800$ (Figure 4.3.2.2-37a)

$\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_N$

$\frac{X_{c.p.}}{\ell_N} = 0.488$ (Figure 4.2.2.1-18a)

$$\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_N = \frac{\ell_N}{c_{r_e}} \left(\frac{X_{c.p.}}{\ell_N} - 1\right) = \frac{5}{3}\ (0.488 - 1) = -0.853$$

Solution:

$$\frac{X'_{a.c.}}{c_{r_e}} = \frac{\left(\frac{X'_{a.c.}}{c_{r_e}}\right)_N C_{N_{\alpha_N}} + \left(\frac{X'_{a.c.}}{c_{r_e}}\right)_{W(B)} C_{N_{\alpha_{W(B)}}} + \left(\frac{X'_{a.c.}}{c_{r_e}}\right)_{B(W)} C_{N_{\alpha_{B(W)}}}}{C_{N_{\alpha_N}} + C_{N_{\alpha_{W(B)}}} + C_{N_{\alpha_{B(W)}}}}$$ (equation 4.3.2.2-a)

$$= \frac{-0.853\,(0.328) + 0.670\,(2.37) + 0.800\,(0.514)}{0.328 + 2.37 + 0.514}$$

$$= 0.535$$

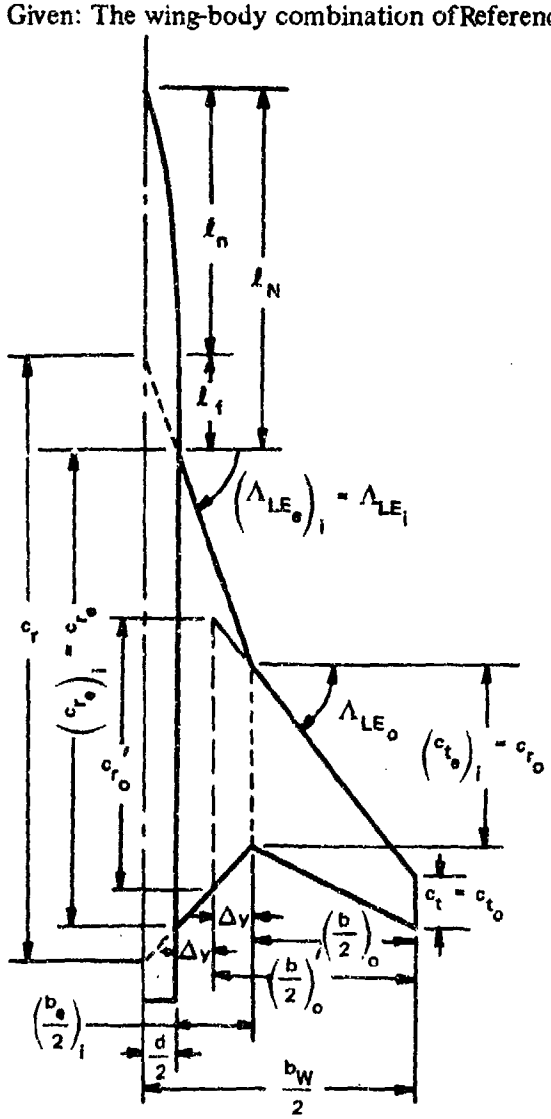
$$\frac{X_{a.c.}}{c_r} = \left(\frac{X'_{a.c.}}{c_{r_e}}\right)\left(\frac{c_{r_e}}{c_r}\right) + \frac{d}{2c_r}\tan\Lambda_{LE} \quad \text{(Equation 4.3.2.2-b)}$$

$$= 0.535\left(\frac{3}{3.74}\right) + \frac{1.5\,(1.0)}{2(3.74)} = 0.630$$

The calculated result compares with a test value of $\frac{X_{a.c.}}{c_r} = 0.62$ from Reference 26.

2. Non-Straight-Tapered Wing-Body Combination

Given: The wing-body combination of Reference 32 designated 6-67-67.



Total-Wing Characteristics:

$A_W = 2.42$ $S_W = 238.0$ sq in. $\lambda_W = 0.086$

$\Lambda_{LE_i} = 70.67^\circ$ $\Lambda_{LE_o} = 51.63^\circ$ $\eta_B = 0.40$

$\Lambda_{TE_i} = -47.37^\circ$ $\Lambda_{TE_o} = 26.62^\circ$ $c_t = 2.29$ in.

$c_r = 26.63$ in. $b_W = 24.0$ in.

Airfoil: 6% hexagonal with maximum thickness at c/3 (streamwise)

Exposed-Wing Characteristics:

$A_e = 1.82$ $\lambda_e = 0.110$ $c_{r_e} = 20.76$ in.

$b_e = 21.0$ in.

Body-Nose Characteristics:

Ogive-cylinder $d = 3.0$ in. $\frac{d}{b_W} = 0.125$

$\ell_n = 10.5$ in. $f_n = 3.50$

$\ell_f = \ell_{forebody} = 5.33$ in. $f_f = 1.78$

$\ell_N = 15.83$ in.

Constructed-Exposed-Inboard-Panel Characteristics:

$(A_e)_i = 0.463 \quad (\lambda_e)_i = 0.374 \quad \left(c_{r_e}\right)_i = 20.76 \text{ in.} \quad \left(\Lambda_{LE_e}\right)_i = \Lambda_{LE_i} = 70.67^o$

$\left(\frac{b_e}{2}\right)_i = 3.30 \text{ in.} \quad \Delta y = 1.65 \text{ in.} \quad (S_e)_i = 94.15 \text{ sq in.}$

Constructed-Exposed-Outboard-Panel Characteristics:

$A'_o = 3.13 \quad \lambda'_o = 0.254 \quad c'_{r_o} = 9.03 \text{ in.} \quad \Lambda'_{LE_o} = \Lambda_{LE_o} = 51.63^o$

$\left(\frac{b}{2}\right)'_o = 8.85 \text{ in.} \quad S'_o = 100.2 \text{ sq in.}$

Additional Characteristics:

$M = 2.01 \; ; \; \beta = 1.744$

Compute:

$\left[\left(C_{N_\alpha}\right)_e\right]_i$ (Section 4.1.3.2)

$\frac{\beta}{\tan \Lambda_{LE_i}} = \frac{1.744}{\tan 70.67^o} = 0.6117; \quad \left[(A \tan \Lambda_{LE})_e\right]_i = (0.463)(\tan 70.67^o) = 1.32$

$\tan \Lambda_{LE_i} \left[\left(C_{N_\alpha}\right)_{e_{theory}}\right]_i = 2.30 \text{ per rad}$ (Figures 4.1.3.2-56c through -56e, interpolated)

$\left[\left(C_{N_\alpha}\right)_{e_{theory}}\right]_i = 0.807 \text{ per rad}$

$\delta_\perp = \frac{\tan^{-1} \frac{0.03}{0.333}}{\cos \Lambda_{LE_i}} = 15.63^o \; ; \; \Delta y_\perp = 5.85 \tan \delta_\perp = 1.638$

$\left[\frac{\left(C_{N_\alpha}\right)_e}{\left(C_{N_\alpha}\right)_{e_{theory}}}\right]_i = 0.920$ (Figure 4.1.3.2-60)

$\left[\left(C_{N_\alpha}\right)_e\right]_i = \left[\frac{\left(C_{N_\alpha}\right)_e}{\left(C_{N_\alpha}\right)_{e_{theory}}}\right]_i \left[\left(C_{N_\alpha}\right)_{e_{theory}}\right]_i = 0.742 \text{ per rad}$

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_i$ (Section 4.1.4.2)

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_i = 0.430$ (Figures 4.1.4.2-26c through -26e, interpolated)

$\left(C_{N_\alpha}\right)'_o$ (Section 4.1.3.2)

$\frac{\tan \Lambda_{LE_o}}{\beta} = \frac{\tan 51.63^o}{1.744} = 0.724$; $(A \tan \Lambda_{LE})'_o \doteq (3.13)(\tan 51.63^o) = 3.95$

$\beta \left[\left(C_{N_\alpha}\right)_{theory}\right]'_o = 4.18$ per rad (Figures 4.1.3.2-56b through -56d, interpolated)

$\left[\left(C_{N_\alpha}\right)_{theory}\right]'_o \doteq 2.40$ per rad

$\delta_\perp = \frac{\tan^{-1} \frac{0.03}{0.333}}{\cos \Lambda_{LE_o}} = 8.30^o$

$\left[\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}}\right]'_o = 0.896$ (Figure 4.1.3.2-60)

$\left(C_{N_\alpha}\right)'_o = \left[\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}}\right]'_o \left[\left(C_{N_\alpha}\right)_{theory}\right]'_o \doteq 2.15$ per rad

$\left(\frac{x_{a.c.}}{c_r}\right)'_i$ (Section 4.1.4.2)

$\left(\frac{x_{a.c.}}{c_r}\right)'_o = 0.863$ (Figures 4.1.4.2-26b through -26d, interpolated)

$\frac{(x'_{a.c.})'_o}{\left(c_{r_e}\right)_i} = \left(\frac{x_{a.c.}}{c_r}\right)'_o \frac{c_{r_o}}{\left(c_{r_e}\right)_i} - \frac{\Delta y}{\left(c_{r_e}\right)_i} \tan \Lambda_{LE_o} + \frac{(b_e)_i}{2\left(c_{r_e}\right)_i} \tan \Lambda_{LE_i}$ (Equation 4.3.2.2-e)

$= 0.863 \frac{9.03}{20.76} - \frac{1.65}{20.76}(1.2631) + \frac{3.30}{20.76}(2.851) = 0.728$

Determine the a.c. location of the exposed composite wing $\frac{x'_{a.c.}}{c_{r_e}}$

$$\frac{x'_{a.c.}}{c_{r_e}} = \frac{\left[\left(C_{N_\alpha}\right)_e\right]_i (S_e)_i \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_i + \left(C_{N_\alpha}\right)'_o S'_o \frac{(x'_{a.c.})'_o}{\left(c_{r_e}\right)_i}}{\left[\left(C_{N_\alpha}\right)_e\right]_i (S_e)_i + \left(C_{N_\alpha}\right)'_o S'_o} \quad \text{(Equation 4.3.2.2-f)}$$

$$= \frac{0.742\,(94.15)\,(0.430) + 2.15\,(100.2)\,(0.728)}{0.742\,(94.15) + 2.15\,(100.2)}$$

$$= 0.655$$

Determine the normal-force-curve slope of the exposed composite wing $\left(C_{N_\alpha}\right)_e$

$$\left(C_{N_\alpha}\right)_e = \frac{\left[\left(C_{N_\alpha}\right)_e\right]_i (S_e)_i + \left(C_{N_\alpha}\right)'_o S'_o}{(S_e)_i + S'_o} \quad \text{(Equation 4.3.2.2-g)}$$

$$= \frac{0.742\,(94.15) + 2.15\,(100.2)}{94.15 + 100.2}$$

$$= 1.468 \text{ per rad}$$

$\left(C_{N_\alpha}\right)_B$ (Section 4.2.1.1)

$$\frac{\beta}{f_n} = \frac{1.744}{3.50} = 0.50 \; ; \frac{f_f}{f_n} = \frac{1.78}{3.50} = 0.51$$

$\left(C_{N_\alpha}\right)_B = 2.78$ per rad (Figure 4.2.1.1-21a)

Interference factors (Section 4.3.1.2) (See Step 11 of Datcom method for correct geometric parameters, Page 4.3.2.2-16.)

$K_{W(B)} = 1.10$ (figure 4.3.1.2-10 at $\frac{d}{b_W} = 0.125$)

$K_{B(W)}$

$$\beta A_c (1 + \lambda_e)\left(\frac{\tan \Lambda_{LE_i}}{\beta} + 1\right) = (1.744)\,(1.82)\,(1.110)\left(\frac{2.851}{1.744} + 1\right) = 9.28;$$

therefore, use Figure 4.3.1.2-11a.

$$\left[\beta \left(C_{N_\alpha}\right)_e (\lambda_e + 1)\left(\frac{b}{d} - 1\right)\right] = 1.744\,(1.468)\,(1.110)\,(7.0) = 19.89$$

$$\beta \cot \Lambda_{LE_i} = (1.744)(0.3508) = 0.612; \quad \frac{\beta d}{\left(c_{r_e}\right)_i} = \frac{(1.744)(3.0)}{20.76} = 0.252$$

$$K_{B(W)}\left[\beta\left(C_{N_\alpha}\right)_e (\lambda_e + 1)\left(\frac{b}{d} - 1\right)\right] = 2.90 \quad \text{(Figure 4.3.1.2-11a)}$$

$$K_{B(W)} = 0.147$$

Component normal-force-curve slopes, referred to S_W

$$C_{N_{\alpha_{W(B)}}} = K_{W(B)}\left(C_{N_\alpha}\right)_e \frac{(S_e)_i + S'_c}{S_W} = 1.10\,(1.468)\frac{94.15 + 100.2}{238.0} = 1.32 \text{ per rad}$$

$$C_{N_{\alpha_{B(W)}}} = K_{B(W)}\left(C_{N_\alpha}\right)_e \frac{(S_e)_i + S'_o}{S_W} = 0.147\,(1.468)\frac{94.15 + 100.2}{238.0} = 0.176 \text{ per rad}$$

$$C_{N_{\alpha_N}} = \left(C_{N_\alpha}\right)_B \frac{\pi d^2}{4S_W} = (2.78)\frac{\pi 9}{4(238)} = 0.0826 \text{ per rad}$$

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)}$ The interference effect of the body is neglected.

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} = \frac{x'_{a.c.}}{c_{r_e}} = 0.655 \text{ (calculated on Page 4.3.2.2-24)}$$

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)}$ (See Step 11 of Datcom method for correct geometric parameters, Page 4.3.2.2-16.)

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} = 0.640 \text{ (Figure 4.3.2.2-37a)}$$

$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N$

$$\frac{x_{c.p.}}{\ell_N} = 0.405 \text{ (Figure 4.2.2.1-18a)}$$

$$\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N = \frac{\ell_N}{c_{r_e}}\left(\frac{x_{c.p.}}{\ell_N} - 1\right) = \frac{15.83}{20.76}(0.405 - 1) = -0.454$$

Solution:

$$\frac{x'_{a.c.}}{c_{r_e}} = \frac{\left(\frac{x'_{a.c.}}{c_{r_e}}\right)_N C_{N_{a_N}} + \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{W(B)} C_{N_{a_{W(B)}}} + \left(\frac{x'_{a.c.}}{c_{r_e}}\right)_{B(W)} C_{N_{a_{B(W)}}}}{C_{N_{a_N}} + C_{N_{a_{W(B)}}} + C_{N_{a_{B(W)}}}} \quad \text{(Equation 4.3.2.2-a)}$$

$$= \frac{-0.454\,(0.0826) + 0.655\,(1.32) + 0.640\,(0.176)}{0.0826 + 1.32 + 0.176}$$

$$= 0.595$$

$$\frac{x_{a.c.}}{c_r} = \left(\frac{x'_{a.c.}}{c_{r_e}}\right)\left(\frac{c_{r_e}}{c_r}\right) + \frac{d}{2c_r} \tan \Lambda_{LE_i} \quad \text{(Equation 4.3.2.2-b)}$$

$$= 0.595 \quad \frac{20.76}{26.63} + \frac{3}{2(26.63)} \quad (2.851)$$

$$= 0.624$$

The calculated result compares with a test value of $\frac{x_{a.c.}}{c_r} = 0.626$ from Reference 32.

4.3.3 WING-BODY DRAG

4.3.3.1 WING-BODY ZERO-LIFT DRAG

The problem of estimating the zero-lift drag of a wing-body combination is one of properly accounting for the mutual interferences that exist between its components. There are two principal approaches to the problem. One attempts to isolate the individual interferences, and the other combines the drag of components with the interference drag and analyzes the total configuration. The Datcom method for subsonic speeds consists of applying an interference correction factor to the skin-friction and pressure-drag contributions of the exposed components. The method presented for transonic speeds treats the configuration as a unit by simply adding the drag contributions of the gross components. At supersonic speeds the wing-body zero-lift drag is obtained by summing the drag contributions of the exposed wing and the isolated body. The methods presented for the subsonic-, transonic-, and supersonic-speed regimes are for a fully turbulent boundary layer over the body and the wing.

A. SUBSONIC

Subsonic wing-body interference is caused by several phenomena, of which two are especially important. First, the wing and body produce supervelocities due to thickness that increase the skin friction in the vicinity of the wing-body junction. Second, the confluence of boundary layers at the junction can cause premature boundary-layer separation, which, however, can sometimes be prevented or at least postponed by proper fillet design. It has not been possible to establish a general method for estimating interference drag. Although the Datcom method uses interference correction factors based on experimental results for wing-body combinations, it should be pointed out that most of the bodies were conventional, ogive-cylinder combinations of high fineness ratio, and no detailed investigation has been made to evaluate body effects. Therefore, the method should not be construed as pertaining to generalized wing-body combinations with arbitrary body shapes.

The Datcom method is that of reference 1 and is applicable to wing-body configurations consisting of a body of revolution in combination with the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal planforms)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

DATCOM METHOD

The subsonic zero-lift drag coefficient of a wing-body combination, based on the reference area, is determined by adding the drag coefficients of the exposed components and applying an interference correction factor to the skin-friction and pressure-drag contributions. The component contributions of the wing and body are determined by the methods of Sections 4.1.5.1 and 4.2.3.1, respectively. This approach is summarized by

$$\left(C_{D_0}\right)_{WB} = \left\{ C_{f_W} \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4 \right] R_{L.S.} \frac{(S_{wet})_e}{S_{ref}} + C_{f_B} \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\frac{\ell_B}{d} \right] \frac{(S_B)_e}{S_{ref}} \right\} R_{WB} + C_{D_b} \frac{S_B}{S_{ref}} \qquad 4.3.3.1\text{-a}$$

where

C_{f_W} is the turbulent flat-plate skin-friction coefficient of the wing (or wing panel in the case of composite wings), including roughness effects, as a function of Mach number and the Reynolds number based on the reference length ℓ. This value is determined as discussed in paragraph A of Section 4.1.5.1. The reference length ℓ is the mean aerodynamic chord $\bar{c}_e$ of the exposed wing (or exposed wing panels in the case of composite wings).

C_{f_B} is the turbulent flat-plate skin-friction coefficient of the body, including roughness effects, as a function of Mach number and the Reynolds number based on the reference length ℓ. This value is determined as discussed in paragraph A of Section 4.1.5.1. The reference length ℓ is the actual body length ℓ_B.

$(S_{wet})_e$ is the wetted area of the exposed wing (or exposed wing panels in the case of composite wings).

$(S_S)_e$ is the exposed wetted area of the body (the wetted area of the isolated body minus the surface area covered by the wing at the wing-body juncture).

S_{ref} is the reference area.

R_{WB} is the wing-body interference correlation factor obtained from figure 4.3.3.1-37 as a function of Mach number and the fuselage Reynolds number based on the actual body length ℓ_B.

The remaining parameters in equation 4.3.3.1-a are presented in either Section 4.1.5.1 or Section 4.2.3.1.

In treating non-straight-tapered wings the wing zero-lift drag contribution is obtained for the exposed inboard and the outboard panels separately (based on the reference area) and then added. Curved planforms are approximated by combinations of trapezoidal panels, in which case two such panels are usually sufficient to give a satisfactory result. An ogee planform has been chosen for the sample problem to illustrate how the method is applied to curved planforms, as well as to show the general application of the method to double-delta and cranked planforms.

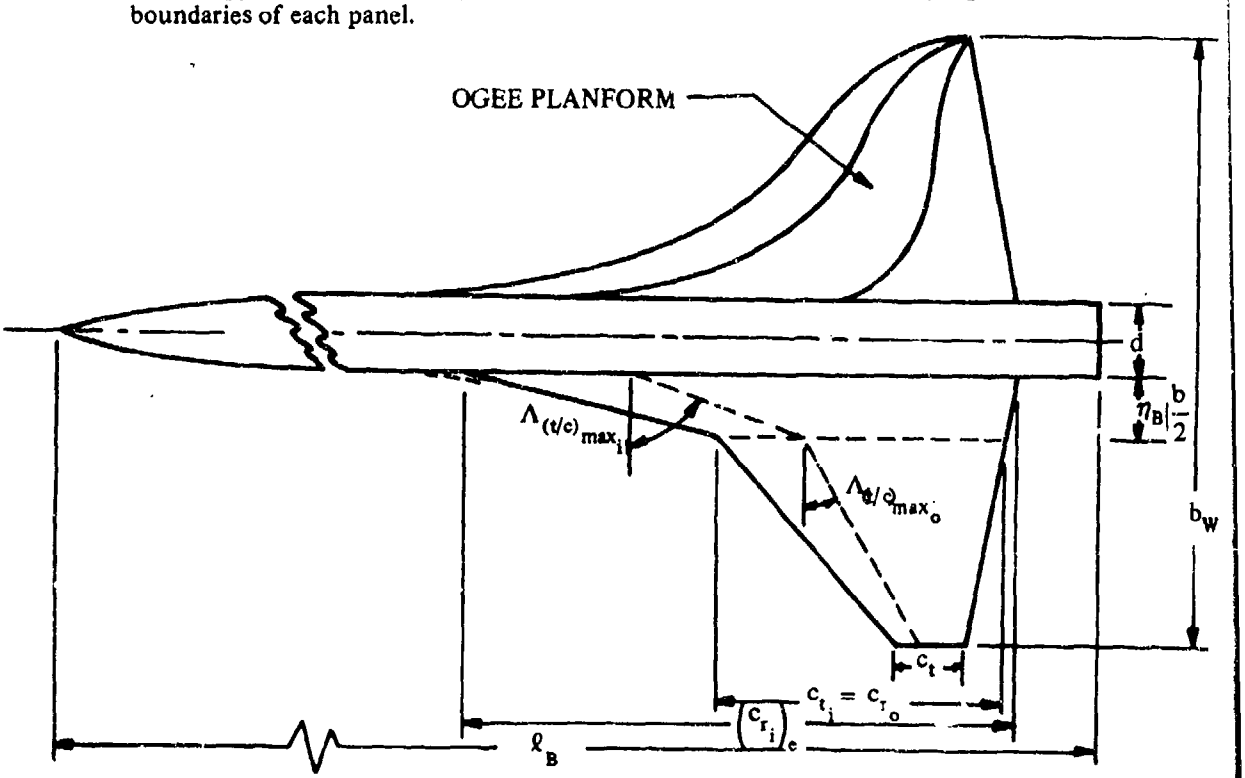
Non-straight-tapered wing geometric parameters are presented in Section 2.2.2.

The wing-body interference correlation factor R_{WB} was developed in reference 1 by determining the ratio of test values of C_{D_0} to values predicted on the basis of $R_{WB} = 1.0$ for several wing-body combinations. Both conventional, trapezoidal planforms and composite planforms have been used in the correlation; however, most of the bodies were conventional ogive-cylinders of high fineness ratio. Composite planform data are limited to values of fuselage Reynolds number below 2.4×10^7. The curves for values of $R_{\ell_{fus}} > 2.4 \times 10^7$ were generated using the basic prediction method of reference 2, which has been correlated with flight-test data. It should also be noted that the correlation does not include data below $M = 0.25$.

A comparison of test data for 15 configurations with $\left(C_{D_0}\right)_{WB}$ calculated by this method is presented as table 4.3.3.1-A (taken from reference 1). The results are indicative of the accuracy that can be expected when applying the method to configurations with $R_{\ell_{fus}} \leq 2.4 \times 10^7$. The validity of the method for configurations with non-straight-tapered wings has not been verified above $R_{\ell_{fus}} > 2.4 \times 10^7$; however, the accuracy of the basic prediction method as applied to configurations consisting of conventional, trapezoidal wings mounted on ogive-cylinders of high fineness ratio indicates that accuracy to within ±10 percent can be expected. It should be noted that the test values in table 4.3.3.1-A have been corrected to remove base drag and that the calculated values do not include the base-drag term of equation 4.3.3.1-a.

Sample Problem

Given: A wing-body configuration of reference 14. The ogee planform is approximated by a double-delta planform with a streamwise tip. The inboard and outboard panels of the double-delta wing have been selected to have leading and trailing edges which closely approximate the sweeps of the curved edges. The sweeps of the maximum thickness lines of the inboard and outboard panels closely approximate the sweep of the maximum thickness line of the ogee planform within the boundaries of each panel.



SKETCH (a)

Ogee Planform:

$S_W = S_{ref} = 21.75$ sq in. $\quad S_{W_e} = 16.57$ sq in. $\quad t/c = 0.02$

Airfoil section: Hexagonal with ridge lines at 0.30c and 0.70c (x_t @ 0.30c)

Body:

Ogive-cylinder $\quad \ell_B = 14.216$ in. $\quad d = 0.875$ in. $\quad f_{fus} = 16.25$

$(S_S)_e = 33.70$ sq in. (fuselage area covered by wing at wing-body juncture is removed from isolated body wetted area).

$\frac{(S_S)_e}{S_{ref}} = 1.550 \quad \frac{d_b}{d} = 1.0 \quad \frac{S_B}{S_{ref}} = 0.0276 \quad \frac{(S_S)_e}{S_B} = 56.04$

Double-Delta Approximation:

Inboard panel:

$(S_i)_e$ = 7.21 sq in. $\left(S_{wet_i}\right)_e$ = 14.42 sq in. $\left(S_{wet_i}\right)_e / S_{ref}$ = 0.663

$(\bar{c}_i)_e$ = 5.11 in. $\Lambda_{(t/c)_{max_i}} = 70^o$ $(t/c)_i$ = 0.02

Outboard panel:

$(S_o)_e$ = 9.67 sq in. $\left(S_{wet_o}\right)_e$ = 19.34 sq in. $\left(S_{wet_o}\right)_e / S_{ref}$ = 0.889

$(\bar{c}_o)_e$ = 2.375 in. $\Lambda_{(t/c)_{max_o}} = 31^o$ $(t/c)_o$ = 0.02

Additional Characteristics:

M = 0.70 R_ℓ = 2.5×10^6 per ft

Polished metal surface (assume k = 0.03×10^{-3} in.)

Compute:

Determine C_f for each component (Section 4.1.5.1)

Body

$R_\ell = (2.50 \times 10^6)(\ell_B) = (2.5 \times 10^6)(14.216/12) = 2.96 \times 10^6$

$\ell/k = 14.216/(.03 \times 10^{-3}) = 4.74 \times 10^5$; cutoff $R_\ell \simeq 4.5 \times 10^7$ (figure 4.1.5.1-27)

Since cutoff R_ℓ > calculated R_ℓ, read C_{f_B} at calculated R_ℓ.

C_{f_B} = 0.00354 (figure 4.1.5.1-26)

Inboard Panel

$R_\ell = (2.5 \times 10^6)(\bar{c}_i)_e = (2.5 \times 10^6)(5.11/12) = 1.065 \times 10^6$

$\ell/k = 5.11/(.03 \times 10^{-3}) = 1.70 \times 10^5$; cutoff $R_\ell \simeq 1.4 \times 10^7$ (figure 4.1.5.1-27)

Since cutoff $R_\ell \simeq$ calculated R_ℓ, read $\left(C_{f_W}\right)_i$ at calculated R_ℓ.

$\left(C_{f_W}\right)_i$ = 0.00425 (figure 4.1.5.1-26)

Outboard Panel

$R_\ell = (2.5 \times 10^6)(\bar{c}_o)_e = (2.5 \times 10^6)(2.375/12) = 4.95 \times 10^5$

$\ell/k = 2.375/(.03 \times 10^{-3}) = 7.92 \times 10^4$; cutoff $R_\ell \simeq 6.5 \times 10^6$ (figure 4.1.5.1-27)

Since cutoff R_ℓ > calculated R_ℓ, read $\left(C_{f_W}\right)_o$ at calculated R_ℓ.

$\left(C_{f_W}\right)_o = 0.00488$ (figure 4.1.5.1-26)

Determine the zero-lift drag contribution of the exposed inboard and outboard panels (Section 4.1.5.1).

Inboard panel

$\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] = 1.021$ (figure 4.1.5.1-28a, for L = 1.2)

$\cos \Lambda_{(t/c)_{max_i}} = \cos 70^o = 0.342$

$(R_{L.S.})_i = 1.055$ (figure 4.1.5.1-28b, interpolated using dashed lines)

$$\left(C_{D_0}\right)_i = \left(C_{f_W}\right)_i \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] R_{L.S.} \frac{\left(S_{wet_i}\right)_e}{S_{ref}} = (0.00425)(1.021)(1.055)(0.663)$$

$= 0.003035$ (based on S_{ref})

Outboard panel

$\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] = 1.021$ (figure 4.1.5.1-28a, for L = 1.2)

$\cos \Lambda_{(t/c)_{max_o}} = \cos 31^o = 0.8572$

$(R_{L.S.})_o = 1.180$ (figure 4.1.5.1-28b, interpolated using solid lines)

$$\left(C_{D_0}\right)_o = \left(C_{f_W}\right)_o \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] R_{L.S.} \frac{\left(S_{wet_o}\right)_e}{S_{ref}}$$

$= (0.00488)(1.021)(1.180)(0.889) = 0.00523$ (based on S_{ref})

Determine the zero-lift drag contribution of the isolated body (Section 4.2.3.1)

Zero-lift drag exclusive of base drag

$$\left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\,\frac{\ell_B}{d}\right] = 1.054$$

$$C_{f_B}\left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\frac{\ell_B}{d}\right]\frac{(S_S)_e}{S_{ref}} = (0.00354)\,(1.054)\,(1.550) = 0.00578 \text{ (based on } S_{ref})$$

Base-drag coefficient

$$C_{D_b} = 0.029\left(\frac{d_b}{d}\right)^3 \Big/ \sqrt{\left(C_{D_f}\right)_b} \quad \text{(equation 4.2.3.1-b)}$$

where $\left(C_{D_f}\right)_b$ is the zero-lift drag coefficient exclusive of the base drag,

based on body base area; i.e.,

$$\left(C_{D_f}\right)_b = C_{f_B}\left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\,\frac{\ell_B}{d}\right]\frac{(S_S)_e}{S_B}$$

$$= (0.00354)\,(1.054)\,(56.04) = 0.209$$

$$C_{D_b} = (0.029)\,(1.0)^3 / \sqrt{0.209} = 0.0634 \quad \text{(based on } S_B)$$

Determine the wing-body correlation factor R_{WB}

$$R_{WB} = 0.955 \quad \text{(figure 4.3.3.1-37)}$$

Solution:

$$\left(C_{D_0}\right)_{WB} = \left\{C_{f_W}\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] R_{L.S.}\frac{(S_{wet})_e}{S_{ref}} + C_{f_B}\left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\,\frac{\ell_B}{d}\right]\frac{(S_S)_e}{S_{ref}}\right\} R_{WB}$$

$$+ C_{D_b}\,\frac{S_B}{S_{ref}} \quad \text{(equation 4.3.3.1-a)}$$

$$= \left\{\left[(0.003035) + (0.00523)\right] + (0.00578)\right\}(0.955) + (0.0634)\,(0.0276)$$

$$= 0.0152 \text{ (based on } S_{ref})$$

The test value from reference 14, corrected to remove base drag, is 0.0131. The corresponding calculated value is 0.0152 - 0.00175 = 0.01345

B. TRANSONIC

Interference effects in the transonic range are generally greater than those in the subsonic region, because of the higher local velocities of the individual components and the greater propagation of these perturbations from their source. There often exist large supersonic regions that contribute substantially to the wave drag Many theoretical attempts have been made to correlate these effects in the transonic range, but until the advent of the area-rule concept, none of them proved very satisfactory.

The area-rule method is based on supersonic linear theory, which assumes that pressure disturbances are propagated in the direction of the Mach lines and do not diminish with distance. If it is assumed that these concepts can be applied in a limiting case at a Mach number of one, where Mach lines are normal to the flow direction, it can also be assumed that at large distances from the body the disturbances are independent of the arrangement of the components and only a function of the cross-sectional-area distribution. This means that the drag of a wing-body combination can be calculated as though the combination were a body of revolution with equivalent-area cross sections.

In addition to affording a means of estimating drag by calculation or by testing a simplified model (body of revolution) in the transonic range, the area rule is extremely useful as a design tool, since it indicates the most desirable way to arrange the vehicle components for minimum wave drag. The most common example of this is to indent, or "coke-bottle," a fuselage enough to permit the wing to be added without a marked increase in the over-all area distribution. As is obvious from the body-of-revolution wave-drag curves, it is always desirable from the wave-drag point of view to have a body of as high a fineness ratio as possible. However, it should be remembered that "coke-bottling" should be used judiciously, to avoid undesirable local effects.

The linear-theory wave drag of a smooth, pointed, closed body of revolution was first given by von Kármán (reference 3) as

$$C_D = \frac{1}{2\pi S_{ref}} \int_0^{\ell_B} \int_0^{\ell_B} \frac{d^2S}{dx^2} \frac{d^2S}{d\xi^2} \ell n (x - \xi) \, dx d\xi \qquad 4.3.3.1\text{-b}$$

where

ℓ_B is the body length.

x is any point on the longitudinal axis; $x = 0$ at the nose and $x = \ell_B$ at the aft end.

ξ is any point on the longitudinal axis; $\xi = 0$ at the nose and $\xi = \ell_B$ at the aft end (not necessarily the same point as x).

S is the cross-sectional area of the body at any point x.

$\frac{d^2S}{dx^2}$ and $\frac{d^2S}{d\xi^2}$ are obtained from the area distribution determined in step 1 of paragraph C below.

S_{ref} is the reference area, usually the total wing area.

This equation is subject to the conditions:

1. $\left(\frac{dS}{dx}\right)_{x=0} = \left(\frac{dS}{dx}\right)_{x=\ell_B} = 0$

2. The body is slender, in accordance with the usual slender-body restrictions (reference 3).

3. No discontinuities in dS/dx occur anywhere along the body.

Additional terms have been derived that account for the condition $(dS/dx)_{x=\ell_B} \neq 0$ and for finite discontinuities in dS/dx along the body. References 3, 4, 5, and 6 pertain to these conditions.

References 7 and 8 contain numerical methods of evaluating equation 4.3.3.1-b. However, the solution of this equation by hand is tedious, and automatic computing equipment is invariably used. The preparation of the area-distribution plot for a given configuration is usually performed manually.

The accuracy of this method varies with the smoothness and fineness ratio of the equivalent body. Studies of the accuracy of the area rule are given in references 8, 9, 10, and 11.

The Datcom method is at best approximate and consists of simply adding the zero-lift drag coefficients of the individual isolated components. Since the exposed wetted area of a wing-body combination is less than the sum of the wing-alone and body-alone wetted areas, this amounts to adding an increment to the wing-body drag of the combination to account for interference effects.

The interference drag is usually positive for configurations not specifically contoured to reduce this drag component. However, for area-ruled configurations, this interference drag can become negative.

The Datcom method is applicable only to configurations with conventional, trapezoidal wings.

DATCOM METHOD

At the present it is recommended that the transonic zero-lift drag coefficient of a wing-body combination be approximated by adding the drag coefficients based on the total wetted area of each individual component and referred to a common reference area. This approach is summarized by

$$\left(C_{D_0}\right)_{WB} = \left(C_{D_0}\right)_W + \left(C_{D_0}\right)_B \frac{S_B}{S_{ref}} \qquad 4.3.3.1\text{-c}$$

where

$\left(C_{D_0}\right)_W$ is the zero-lift drag coefficient of the wing, based on the reference area, obtained from paragraph B of Section 4.1.5.1; i.e.,

$$\left(C_{D_0}\right)_W = \left(C_{D_f} + C_{D_w}\right)_W \quad \text{(equation 4.1.5.1-g)}$$

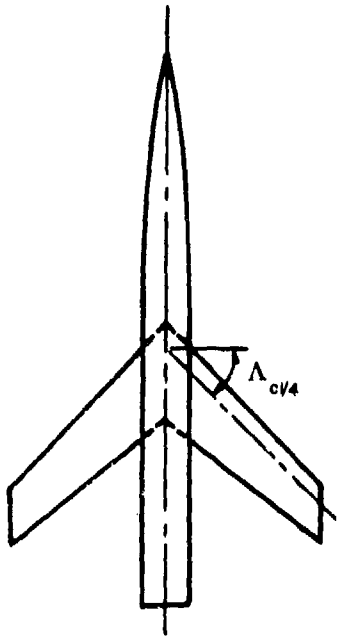
$\left(C_{D_0}\right)_B$ is the zero-lift drag coefficient of the body, based on body base area, obtained from paragraph B of Section 4.2.3.1; i.e.,

$$\left(C_{D_0}\right)_B = \left(C_{D_f}\right)_B + C_{D_P} + C_{D_b} + \left(C_{D_w}\right)_B \quad \text{(equation 4.2.3.1-e)}$$

S_B/S_{ref} is the ratio of the body base area to the reference area.

Sample Problem

Given: The swept-wing cylindrical-body configuration of reference 19.



Body Characteristics:

Ogive-cylinder $\ell_B = 43.0$ in. $d_{max} = d_b = 3.75$ in.

$\ell_B/d = 11.47$ $S_B = 11.05$ sq in. $\frac{S_S}{S_B} = 40.19$

Wing Characteristics:

$A = 4.0$ $\Lambda_{c/4} = 45^o$ $\lambda = 0.60$ $\bar{c} = 6.125$ in.

$S_W = S_{ref} = 144$ sq in. $S_{wet} = 288$ sq in.

NACA 65A006 airfoil (x_t @ 0.50c) $t/c = 0.06$

Additional Characteristics:

$R_{\ell_{M=0.6}} = 2.50 \times 10^5$ per in. $0.80 \le M \le 1.2$

Polished metal surface (assume $k = 0.03 \times 10^{-3}$ in.)

Compute:

The final calculations are presented in table form on page 4.3.3.1-13. Many of the quantities listed below appear as columns in the table.

Wing zero-lift drag coefficient $\left(C_{D_0}\right)_W$ (Section 4.1.5.1)

Determine the skin-friction drag coefficient.

$R_\ell = (2.50 \times 10^5)(\bar{c}) = (2.50 \times 10^5)(6.125) = 1.53 \times 10^6$

$\ell/k = 6.125/(0.03 \times 10^{-3}) = 2.04 \times 10^5$; cutoff $R_{\ell_{M=0.6}} \simeq 1.6 \times 10^7$ (figure 4.1.5.1-27)

Since cutoff $R_\ell >$ calculated R_ℓ, read $(C_f)_W$ at calculated R_ℓ.

$(C_f)_W = 0.0040$ (figure 4.1.5.1-26 @ M = 0.60)

$$\left(C_{D_f}\right)_W = (C_f)_W \left[1 + L\left(\frac{t}{c}\right)\right] \frac{S_{wet}}{S_{ref}}$$ (equation 4.1.5.1-c)

$$= (0.0040)\,[1 + 1.2(0.06)]\,\frac{288}{144}$$ ($L = 1.2$ for $x_t > 0.30c$) $= 0.00858$

Determine and construct the variation of $\left(C_{D_w}\right)_W$ with Mach number for an unswept wing.

$$A\left(\frac{t}{c}\right)^{1/3} = (4.0)(0.392) = 1.568$$

① M	② $\frac{\sqrt{\lvert M^2-1\rvert}}{(t/c)^{1/3}}$	③ $\frac{\left(C_{D_w}\right)_W}{(t/c)^{5/3}}$ fig 4.1.5.1-29	④ $\left(C_{D_w}\right)_W$ ③ (0.0092)

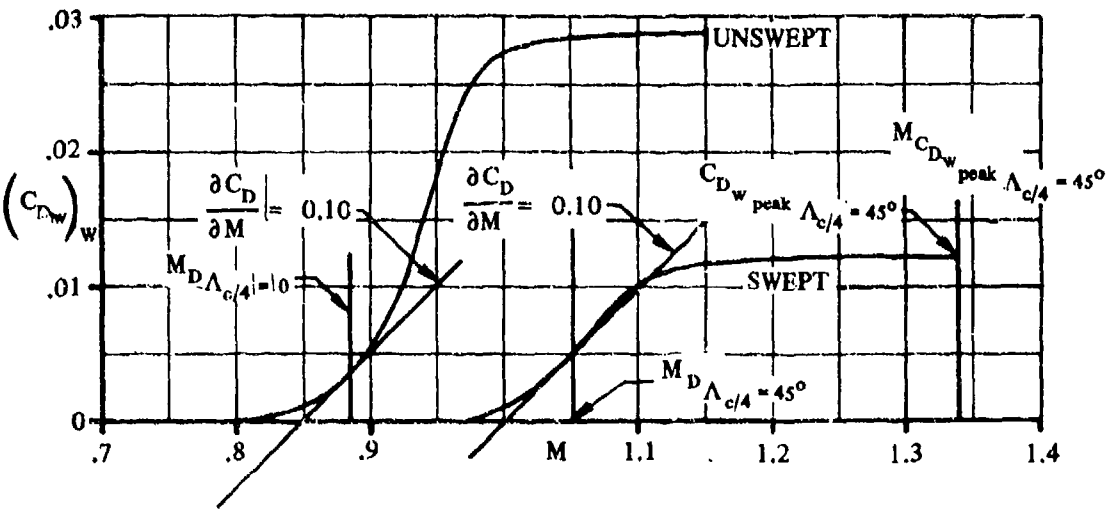
Plot $\left(C_{D_w}\right)_W$ vs M for the unswept wing (sketch (a))



SKETCH (a)

Read the following values from the curve of $\left(C_{D_w}\right)_W$ vs M for the unswept wing:

$$M_{D_{\Lambda_{c/4}=0}} = 0.885$$

$$C_{D_{w_{peak}\Lambda_{c/4}=0}} = 0.0288$$

$$M_{C_{D_{w_{peak}}\Lambda_{c/4}=0}} = 1.125$$

Apply sweep corrections:

$$M_{D_{\Lambda_{c/4}=45^o}} = \frac{M_{D_{\Lambda_{c/4}=0}}}{(\cos 45^o)^{1/2}} = 1.05 \quad \text{(equation 4.1.5.1-d)}$$

$$C_{D_{w_{peak}\Lambda_{c/4}=45^o}} = C_{D_{w_{peak}\Lambda_{c/4}=0}} (\cos 45^o)^{2.5} = 0.0121 \quad \text{(equation 4.1.5.1-e)}$$

$$M_{C_{D_{w_{peak}\Lambda_{c/4}=45^o}}} = \frac{M_{C_{D_{w_{peak}\Lambda_{c/4}=0}}}}{(\cos 45^o)^{1/2}} = 1.34 \quad \text{(equation 4.1.5.1-f)}$$

Construct the curve of $\left(C_{D_w}\right)_W$ vs M for the swept wing using the straight-wing curve to aid in fairing (see sketch (a)). List the swept-wing values in column (3) of the calculation table on page 4.3.3.1-13.

The wing zero-lift drag coefficient is tabulated in column (4) of the calculation table on page 4.3.3.1-13 as

$$\left(C_{D_0}\right)_W = \left(C_{D_f} + C_{D_w}\right)_W \quad \text{(equation 4.1.5.1-g)}$$

Body zero-lift drag coefficient $\left(C_{D_0}\right)_B$ (Section 4.2.3.1)

Determine the skin-friction drag coefficient.

$$R_\ell = (2.50 \times 10^5)(\ell_B) = (2.50 \times 10^5)(43.0) = 1.075 \times 10^7$$

$$\ell/k = 43.0/(0.03 \times 10^{-3}) = 1.433 \times 10^6; \text{ cutoff } R_{\ell_{M=0.6}} \approx 1.3 \times 10^8 \quad \text{(figure 4.1.5.1-27)}$$

Since cutoff R_ℓ > calculated R_ℓ, read $(C_f)_B$ at calculated R_ℓ.

$(C_f)_B = 0.00288$ (figure 4.1.5.1-26 @ M = 0.60)

$$\left(C_{D_f}\right)_B = (C_f)_B \frac{S_S}{S_B} \quad \text{(equation 4.2.3.1-c)}$$

$$= (0.00288)(40.19) = 0.1157$$

Determine the pressure-drag coefficient.

$$C_{D_P} = (C_f)_{B_{M=0.6}} \left[\frac{60}{(\ell_B/d)^3} + 0.0025 \frac{\ell_B}{d} \right] \frac{S_S}{S_B} \quad \text{(equation 4.2.3.1-d)}$$

$$= 0.00288 \left[\frac{60}{(11.47)^3} + 0.0025\,(11.47) \right] 40.19$$

$$= 0.00792 \text{ (based on } S_B)$$

This value of C_{D_P} is taken to be constant for $0 < M < 1.0$, then reduced linearly to zero at M = 1.2 (see column (6) of calculation table, page 4.3.3.1-13).

Determine the base-drag coefficient.

$$C_{D_b} = 0.029 \left(\frac{d_b}{d}\right)^3 \Big/ \sqrt{\left(C_{D_f}\right)_b} \quad \text{(equation 4.2.3.1-b)}$$

$$\left(C_{D_f}\right)_b = (C_f)_{B_{M=0.6}} \left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025 \frac{\ell_B}{d} \right] \frac{S_S}{S_B} \quad \text{(first term, eq. 4.2.3.1-a)}$$

$$= (C_f)_{B_{M=0.6}} \frac{S_S}{S_B} + C_{D_P} = (0.00288)(40.19) + 0.00792$$

$$= 0.124$$

$$C_{D_b} = (0.029)(1.0)^3 / \sqrt{0.124} = 0.0824 \text{ (at M = 0.6)}$$

$$\left[\frac{C_{D_b}}{\left(\frac{d_b}{d}\right)^2} \right]_{M=0.6} = \frac{0.0824}{(1)^2} = 0.0824$$

With this value and by using the curves of figure 4.2.3.1-24 as guide lines, obtain values of $C_{D_b}/(d_b/d)^2$ for $0.8 < M < 1.2$.

Then $C_{D_b} = \left[C_{D_b}/(d_b/d)^2\right]_{M=0.6}(d_b/d)^2$ (see column ⑦ of calculation table, page 4.3.3.1-13).

Determine the drag-divergence Mach number.

$M_D = 0.98$ (figure 4.2.3.1-25)

Determine the wave-drag coefficient.

The wave-drag coefficient as a f(M) is obtained from figure 4.2.3.1-26 (see column ⑧ of the calculation table, page 4.3.3.1-13).

The body zero-lift drag coefficient is tabulated in column ⑨ of the calculation table on page 4.3.3.1-13 as

$$\left(C_{D_0}\right)_B = \left(C_{D_f}\right)_B + C_{D_P} + C_{D_b} + \left(C_{D_w}\right)_B \quad \text{(equation 4.2.3.1-e)}$$

Solution:

$$\left(C_{D_0}\right)_{WB} = \left(C_{D_0}\right)_W + \left(C_{D_0}\right)_B \frac{S_B}{S_{ref}} \quad \text{(equation 4.3.3.1-c)}$$

$$= \left(C_{D_f} + C_{D_w}\right)_W + \left(C_{D_f} + C_{D_P} + C_{D_b} + C_{D_w}\right)_B \frac{S_B}{S_{ref}}$$

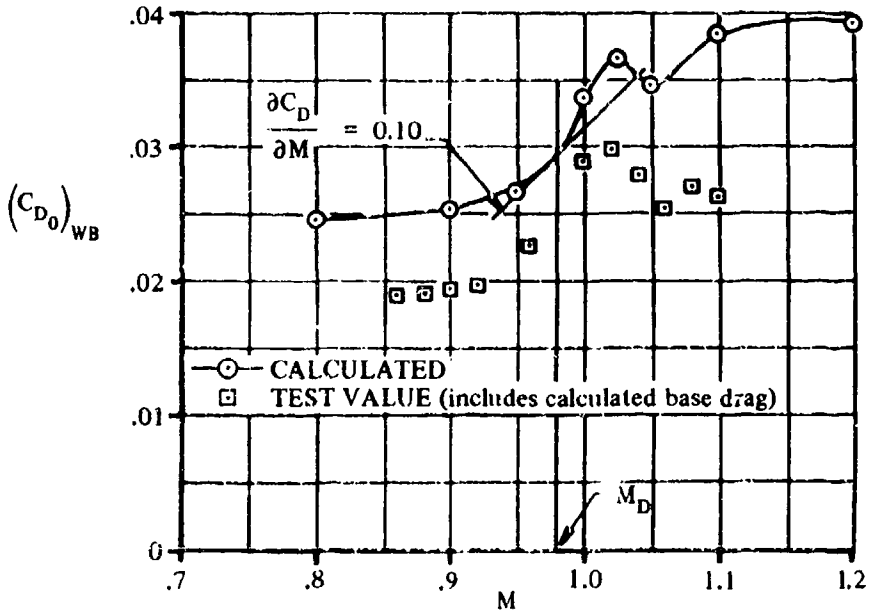
The calculated values of the wing-body zero-lift drag coefficient are compared with modified test results from reference 19 in sketch (b). The drag-divergence Mach number of the isolated body has been used to aid in fairing the curve through the calculated points. The test results presented in reference 19 were corrected to a condition at which the base pressure is equal to the stream static pressure. The test points plotted on sketch (b) have been modified by addition of the calculated base-drag coefficient.



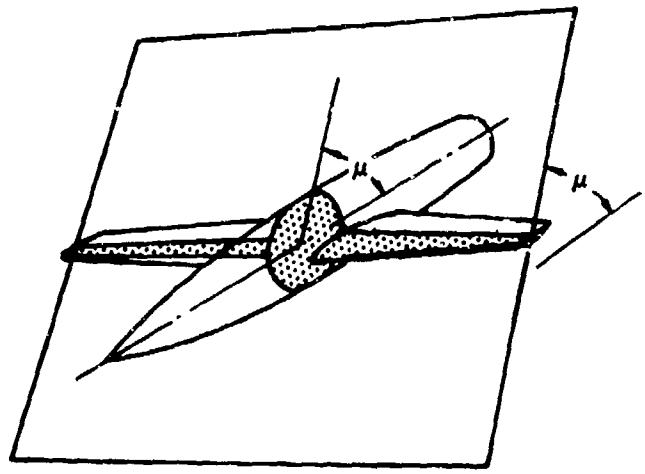
SKETCH (b)

C. SUPERSONIC

The estimation of wing-body drag at supersonic speeds also involves the calculation of interference effects. It is possible by using linear or higher-order theories to calculate some of these effects. However, the calculations require considerable effort and must be tailored carefully to the geometry of the configuration. The equivalent-body technique discussed in paragraph B above has been adapted to supersonic speeds, but with considerable complication. The resulting method, termed the "supersonic area-rule," gives the wave drag, including aerodynamic interferences, at a given Mach number.

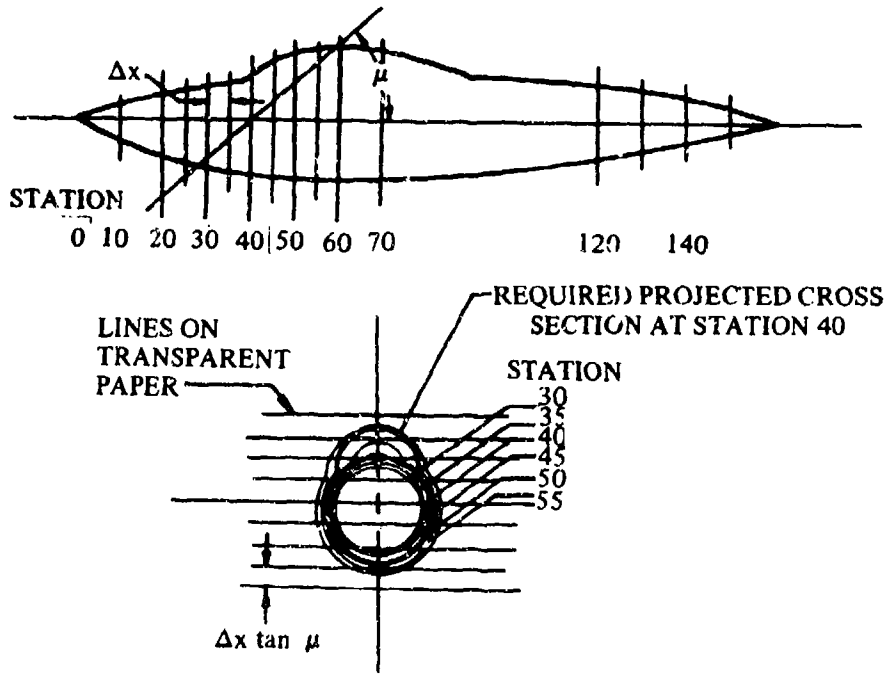
Application of the supersonic area-rule requires automatic computing equipment. If such a computer is to be used, the following steps are required to prepare the machine input information and to interpret the computed drag values obtained.

Step 1. At a series of longitudinal stations compute the cross-sectional area intercepted by planes inclined at the angle $\mu = \sin^{-1}(1/M)$ to the x-axis (see sketch (c)). The areas so determined at each station are then projected on the plane normal to the longitudinal axis. The values of these projected areas are plotted at the intersection of the inclined plane and the longitudinal axis. This plot is the area distribution of the equivalent body of revolution.



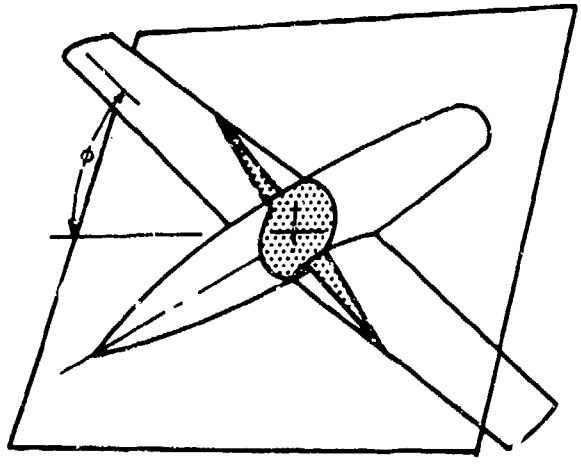
SKETCH (c)

This step can be simplified by using the following graphical procedure. First, construct cross sections normal to the longitudinal axis at an evenly-spaced number of longitudinal stations, say, spaced at Δx. Prepare a set of parallel lines on transparent paper with a spacing equal to $\Delta x \tan \mu$. Each one of these lines corresponds to one of the downstream stations intercepted by the inclined plane. The required projected cross section at a given station x is then determined by overlaying the transparent paper on the given normal cross sections and plotting the intersection of each of the parallel lines with its corresponding given normal-cross-section contour. The curve formed on the transparent paper by connecting the above intersections encloses the required projected area that when integrated is to be plotted at station x. This procedure is illustrated in sketch (d).



SKETCH (d)

Step 2. The procedure of step 1 is repeated for additional cases, where the inclined plane is fixed and the vehicle is rolled at a specified number of roll angles, as shown in sketch (e). For a configuration with four planes of symmetry, such as a symmetrical cruciform missile, only roll angles between 0 and 45^{o} must be considered. For cruciform configurations with two planes of symmetry, roll angles between 0 and 90^{o} should be considered. If there is just one plane of symmetry, roll angles between 0 and 180^{o} need to be considered.



SKETCH (e)

Step 3. The drag for the equivalent body of revolution at each roll angle is then calculated by means of equation 4.3.3.1-b, or by the equation given in, for example, reference 4. These drag values are plotted as a function of roll angle and integrated to determine an average value of C_D. This average drag coefficient is taken to be the wave drag of the configuration at the chosen Mach number.

The number of roll angles required to achieve an accurate value of C_D varies with the configuration. If the C_D vs ϕ plot can be constructed without ambiguity with the number of roll angles chosen, then that number is sufficient. One should be particularly careful of conditions where the Mach angle lies along or very close to the leading edge of a wing, since this condition causes "spikes" in the C_D vs ϕ plot.

If automatic computing equipment is available, the supersonic-area-rule method should be used. Otherwise the Datcom method outlined below may be used.

The Datcom method is taken from reference 1 and is applicable to the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal planforms)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

DATCOM METHOD

The supersonic zero-lift drag coefficient of a wing-body combination, based on the reference area, is determined by adding the drag coefficients of the exposed components. The component contributions of the wing and body are determined by the methods of Sections 4.1.5.1 and 4.2.3.1, respectively. This approach is summarized by

$$\left(C_{D_0}\right)_{WB} = \left(C_{D_0}\right)_W + \left(C_{D_0}\right)_B \frac{S_B}{S_{ref}} \qquad 4.3.3.1\text{-d}$$

where

$\left(C_{D_0}\right)_W$ is the wing zero-lift drag coefficient at supersonic speeds determined as outlined below.

$\left(C_{D_0}\right)_B$ is the body zero-lift drag coefficient at supersonic speeds based on the body base area. This value is obtained from paragraph C of Section 4.2.3.1.

$\frac{S_B}{S_{ref}}$ is the ratio of the body base area to the reference area.

The method of determining the wing zero-lift drag coefficient is essentially that of paragraph C of Section 4.1.5.1, but with the parameters of the exposed wing (or wing panels in the case of composite wings) used to determine the skin-friction and wave-drag contributions. In order to present a more comprehensive method, the procedure of Section 4.1.5.1 as applied to the exposed panel(s) is fully outlined below.

The wing zero-lift drag coefficient is given by

$$\left(C_{D_0}\right)_W = \left(C_{D_f} + C_{D_w}\right)_W \qquad 4.3.3.1\text{-e}$$

where C_{D_f} and C_{D_w} are the supersonic skin-friction drag coefficient and the supersonic wave-drag coefficient, respectively, both based on a common reference area and outlined in the following paragraphs.

Skin-Friction Drag Coefficient

The supersonic skin-friction drag coefficient is given by

$$\left(C_{D_f}\right)_W = \left(C_f\right)_W \frac{\left(S_{wet}\right)_e}{S_{ref}} \qquad 4.3.3.1\text{-f}$$

for a conventional, trapezoidal planform, and

$$\left(C_{D_f}\right)_W = \left(C_{f_W}\right)_i \frac{\left(S_{wet_i}\right)_e}{S_{ref}} + \left(C_{f_W}\right)_o \frac{S_{wet_o}}{S_{ref}} \qquad 4.3.3.1\text{-g}$$

for a non-straight-tapered planform;

where

C_{f_W} is the turbulent flat-plate skin-friction coefficient of the wing (or wing panel in the case of composite wings), including roughness effects, as a function of Mach number and the Reynolds number based on the reference length ℓ. This value is determined as discussed in paragraph A of Section 4.1.5.1. The reference length ℓ is the mean aerodynamic chord $\bar{c}_e$ of the expose wing (or exposed wing panel in the case of composite wings).

$\frac{(S_{wet})_e}{S_{ref}}$ is the ratio of the wetted area of the exposed wing (or exposed wing panel in the case of composite wings) to the reference area.

The subscripts i and o refer to the inboard and outboard panels, respectively, of composite planforms.

Curved planforms are approximated by combinations of trapezoidal panels, in which case two such panels are usually sufficient to give a satisfactory result.

Non-straight-tapered wing geometric parameters are presented in Section 2.2.2.

Wave-Drag Coefficient

The form of the supersonic wave-drag-coefficient equation is in accordance with the results that have been arrived at in linear supersonic theory for the two-dimensional case. The effects of changes in wing planform and variable thickness ratio are accounted for by defining an effective thickness ratio and computing the wave-drag coefficient on a basic planform shape. A distinction is made between wings with sharp-nosed airfoil sections and wings with round-nosed airfoil sections.

Wings With Sharp-Nosed Airfoil Sections

For wings with sharp-nosed airfoil sections

$$\left(C_{D_w}\right)_W = \frac{K}{\beta}\left(\frac{t}{c}\right)^2_{eff} \frac{(S_{bw})_e}{S_{ref}} \qquad 4.3.3.1\text{-h}$$

when the leading edge of the basic wing is supersonic ($\beta \cot \Lambda_{LE_{bw}} \geq 1$), and

$$\left(C_{D_w}\right)_W = K \cot \Lambda_{LE_{bw}} \left(\frac{t}{c}\right)^2_{eff} \frac{(S_{bw})_e}{S_{ref}} \qquad 4.3.3.1\text{-i}$$

when the leading edge of the basic wing is subsonic ($\beta \cot \Lambda_{LE_{bw}} < 1$). The subscript bw refers to the basic wing (straight leading and trailing edges), and

$(S_{bw})_e$ is the area of the exposed basic wing. The selection of the basic planform for composite wings is discussed and illustrated schematically in paragraph C of Section 4.1.5.1.

$\left(\frac{t}{c}\right)_{eff}$ is the effective thickness ratio (for a conventional, trapezoidal planform, use the average thickness ratio of the exposed planform $(t/c)_{av}$). For a nonstraight-tapered planform

the effective thickness ratio is defined in terms of the basic planform and is given by

$$\left(\frac{t}{c}\right)_{eff} = \left[\frac{\int_{r_b}^{b/2}\left(\frac{t}{c}\right)^2 c_{bw}\, dy}{\int_{r_b}^{b/2} c_{bw_l}\, dy}\right]^{1/2} \qquad 4.3.3.1\text{-j}$$

where c_{bw} is the chord of the basic wing and r_b is the average radius of the body at the wing-body juncture. Note that both the chord of the actual wing and the chord of the basic wing appear in the numerator. The denominator is one-half the planform area of the exposed basic wing, so that

$$\left(\frac{t}{c}\right)_{eff} = \frac{\left[\int_{r_b}^{b/2}\left(\frac{t}{c}\right)^2 c_{bw}\, dy\right]^{1/2}}{\left[\frac{(S_{bw})_e}{2}\right]^{1/2}} \qquad 4.3.3.1\text{-j}'$$

Numerical integration of the integrand in the numerator is illustrated in the sample problem.

$\Lambda_{LE_{bw}}$ is the leading-edge sweep of the basic wing.

K is a constant factor for a given sharp-nosed airfoil section. K factors for sharp-nosed airfoils are presented in paragraph C of Section 4.1.5.1. For basic wings with variable thickness ratios the K factor is based on the airfoil section at the average chord of the exposed planform.

Wings With Round-Nosed Airfoil Sections

Wings with round-nosed airfoil sections exhibit a detached bow wave and a stagnation point, and the pressure-drag coefficient increases as a function of Mach number in a manner similar to the stagnation pressure. Consequently, a constant value of K cannot be used for basic wings with round-nosed airfoils.

The wave-drag coefficient of wings with round-nosed airfoil sections is approximated by adding the pressure drag of a blunt leading edge to the wave drag of tne basic wing with an assumed sharp leading edge. By assuming a biconvex shape aft of the leading edge, the wave drag of a wing with a round-nosed leading edge is given by

$$\left(C_{D_w}\right)_w = C_{D_{LE}} + \frac{16}{3\beta}\left(\frac{t}{c}\right)^2_{eff}\frac{(S_{bw})_e}{S_{ref}} \qquad 4.3.3.1\text{-k}$$

when the leading edge of the basic wing is supersonic ($\beta \cot \Lambda_{LE} \geq 1$), and

$$\left(C_{D_w}\right)_w = C_{D_{LE}} + \frac{16}{3}\cot \Lambda_{LE_{bw}}\left(\frac{t}{c}\right)^2_{eff}\frac{(S_{bw})_e}{S_{ref}} \qquad 4.3.3.1\text{-}\ell$$

when the leading edge of the basic wing is subsonic ($\beta \cot \Lambda_{LE_{bw}} < 1$).

The second terms on the right-hand side of equations 4.3.3.1-k and 4.3.3.1-ℓ are the wing wave-drag coefficients of the basic wing with sharp-nosed, biconvex airfoils at the appropriate leading-edge condition, and

$C_{D_{LE}}$ is the pressure-drag coefficient on a swept, cylindrical leading edge obtained as a function of the Mach number and the leading-edge sweep of the basic wing from figure 4.3.3.1-38. The term $2r_{LE_{bw}} \dfrac{b_{bw} - 2r_b}{\cos \Lambda_{LE_{bw}}}$ is the frontal area of the leading edge of the exposed planform. For basic wings with variable thickness ratios the leading-edge radius $r_{LE_{bw}}$ is the radius of the section at the average chord of the exposed planform.

The correlation of cylindrical leading-edge pressure-drag coefficients is derived in reference 12 and has been substantiated over the Mach number range from 0.5 to 8.0 and for sweep angles from 0 to 75°.

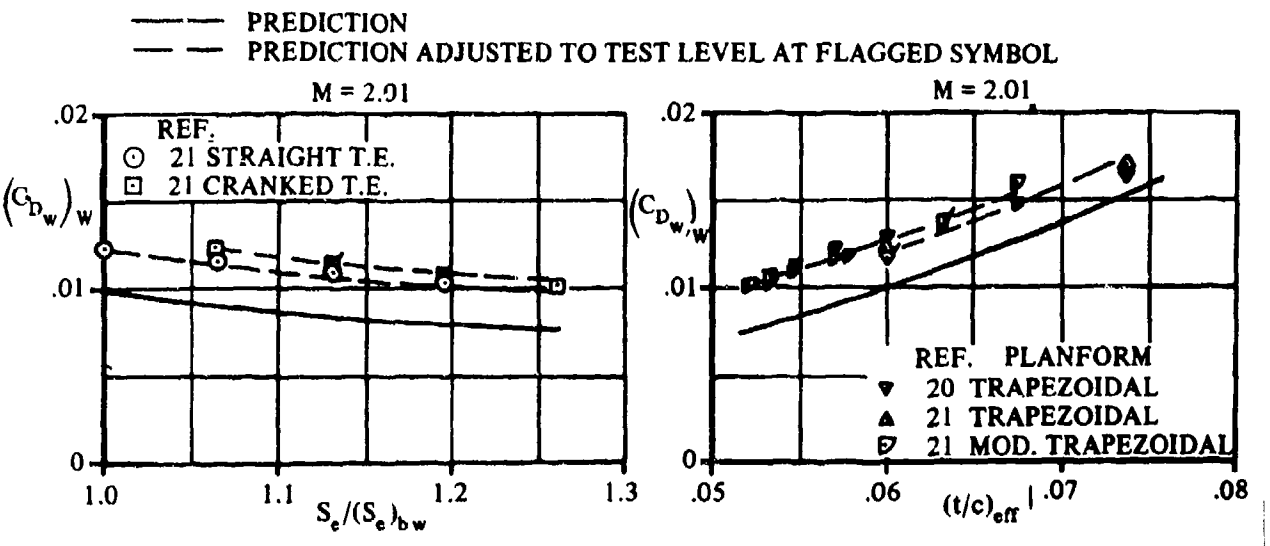
A comparison of test data for 52 configurations with $\left(C_{D_0}\right)_{WB}$ calculated by this method is presented as table 4.3.3.1-B (taken from reference 1). The test configurations consisted of conventional and composite wings with sharp-nosed airfoil sections mounted on ogive-cylinder bodies of high fineness ratio. No detailed investigation has been made to evaluate body effects; therefore, the method should not be construed as pertaining to generalized wing-body combinations with arbitrary body shapes.

Within the limitations of the body shapes investigated, the method shows good agreement with the test results of reference 15. This can be attributed largely to low-thickness-ratio airfoils and small planform modifications – the conditions for which the wing-wave drag method of reference 1 is primarily intended. Predictions for the configurations of the remaining references are generally lower than the test results. This should be expected since the supersonic linear theory used as the basis for the wave-drag prediction is expected to underpredict this contribution for the thicker wing sections and the more extensive planform modifications.

The authors of reference 1 point out that some of the error is quite possibly associated with the manner in which the test data were analyzed. The test results presented in reference 14 were obtained on wing-body configurations without boundary-layer trips and with slightly blunted leading edges. Corrections were applied by the authors of reference 1 to obtain drag values corresponding to fully turbulent flow and sharp leading edges. References 20 and 21 present test results with natural transition. The skin-friction drag for these configurations was predicted by assuming fully turbulent flow over the body and laminar flow over the wing as suggested in the references.

It should be noted that the test values in table 4.3.3.1-B have been corrected to remove base drag, and that the calculated values do not include the base-drag term.

Perhaps the greatest value of the method is that it can be used to predict the supersonic wave-drag increments due to planform modifications and thickness variations. If test data are available for a configuration, the wave drag for a similar configuration can be estimated by predicting the wave drag for both configurations using the Datcom technique, and then applying the increment between the predictions to the test data. Sketches (f) and (g), both taken from reference 1, illustrate the application of this technique to predict the wave-drag variation as a function of planform modification and thickness variation, respectively. Note that although the absolute value of wave drag is not accurately predicted, the trends due to planform modifications and thickness variations are predicted quite well, even for thick, highly modified planforms.



EFFECT OF PLANFORM MODIFICATIONS ON WING WAVE DRAG

SKETCH (f)

EFFECT OF THICKNESS DISTRIBUTION ON WING WAVE DRAG

SKETCH (g)

The limited availability of test data precludes substantiation of the supersonic zero-lift-drag method over wide ranges of planform and flow parameters for configurations having wings with blunt leading edges. A brief statement of an analysis conducted on the blunt-leading-edge planforms of references 23 and 24 is reported in reference 1. It is indicated therein that the method will give satisfactory results for bluntness drag for thin wings.

Sample Problem

Given: The wing-body configuration of reference 15. The configuration consists of a double-delta wing mounted on a cylindrical-ogive body.

Actual Wing Characteristics:

Double-delta planform $A = 1.25$ $\lambda = 0$ $\Lambda_{LE_i} = 83^o$ $\Lambda_{LE_o} = 70^o$

$\Lambda_{TE} = -15^o$ $b/2 = 10.0$ in. $\eta_B = 0.181$ $c_r = 40.0$ in.

$S_W = 319.32$ sq in. t/c (varies, see sketch (h))

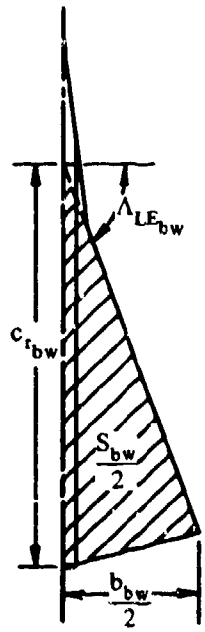
Body Characteristics:

Ogive-cylinder $\ell_B = 40.0$ in. $d_{max} = 2.0$ in. $d_b = 2.0$ in. $\ell_B/d = 20.0$

$\ell_N = 12.0$ in. $f_N = \ell_N/d = 6.0$ $\ell_A = 28.0$ in. $f_A = \ell_A/d = 14.0$

$S_B = 3.14$ sq in. $S_S/S_B = 72.0$ $\theta_N = 8.5^o$

Basic Wing Characteristics (Wave-drag calculations):



Delta planform $A_{bw} = 1.33$ $\lambda_{bw} = 0$ $\Lambda_{LE_{bw}} = 70^{o}$

$\Lambda_{TE_{bw}} = -15^{o}$ $(b/2)_{bw} = 10.0$ in. $c_{r_{bw}} = 30.16$ in.

$(S_{bw})_e = 244.26$ sq in.

Airfoil: hexagonal, sharp leading edge

$\frac{x_1}{c} = 0.4$ $\frac{x_2}{c} = 0.3$ $\frac{x_3}{c} = 0.3$ $(t/c)_{bw} = 0.02$

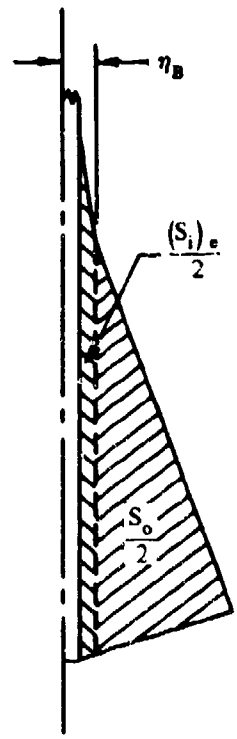
Inboard and Outboard Panel Characteristics (Skin-friction drag calculations):

Inboard panel (exposed)

$\left(c_{r_i}\right)_e = 31.165$ in. $(\lambda_i)_e = 0.794$

$(\bar{c}_i)_e = 28.25$ in. $(S_i)_e = 45.275$ sq in.

$\left(S_{wet_i}\right)_e = 90.55$ sq in. $(b_i/2)_e = 0.81$ in.



Outboard panel

$c_{r_o} = 24.73$ in. $\lambda_o = 0$ $\bar{c}_o = 16.5$ in.

$S_o = 202.52$ sq in. $(S_{wet})_o = 405.04$ sq in.

$b_o/2 = 8.19$ in.

Additional Characteristics:

$M = 2.98$; $\beta = 2.807$ Smooth surfaces (assume $k = 0$)

$S_{ref} = S_{bw} = 301.55$ sq in. $R_\ell = 1.741 \times 10^6$ per in.

Compute:

Determine the wing skin-friction-drag contribution

Inboard panel (exposed)

$$R_\ell = (1.741 \times 10^6)(\bar{c}_i)_e = (1.741 \times 10^6)(28.25) = 4.92 \times 10^7$$

$\ell/k = \infty$, read $\left(C_{f_W}\right)_i$ at calculated R_ℓ

$\left(C_{f_W}\right)_i = 0.00146$ (figure 4.1.5.1-26)

Outboard panel

$$R_\ell = (1.741 \times 10^6)(\bar{c}_o) = (1.741 \times 10^6)(16.5) = 2.87 \times 10^7$$

$\ell/k = \infty$, read $\left(C_{f_W}\right)_o$ at calculated R_ℓ

$\left(C_{f_W}\right)_o = 0.00158$ (figure 4.1.5.1-26)

$$\left(C_{D_f}\right)_W = \left(C_{f_W}\right)_i \frac{\left(S_{wet_i}\right)_e}{S_{ref}} + \left(C_{f_W}\right)_o \frac{S_{wet_o}}{S_{ref}} \quad \text{(equation 4.3.3.1-g)}$$

$$= (0.00146)\frac{90.55}{301.55} + (0.00158)\frac{405.04}{301.55}$$

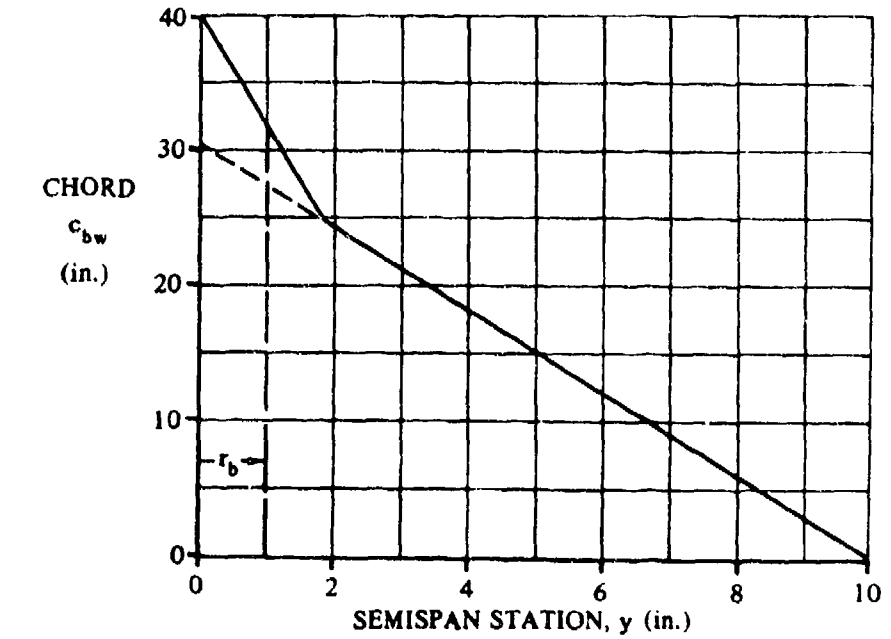
$$= 0.00256 \text{ (based on } S_{ref})$$

Determine the wing wave-drag coefficient.

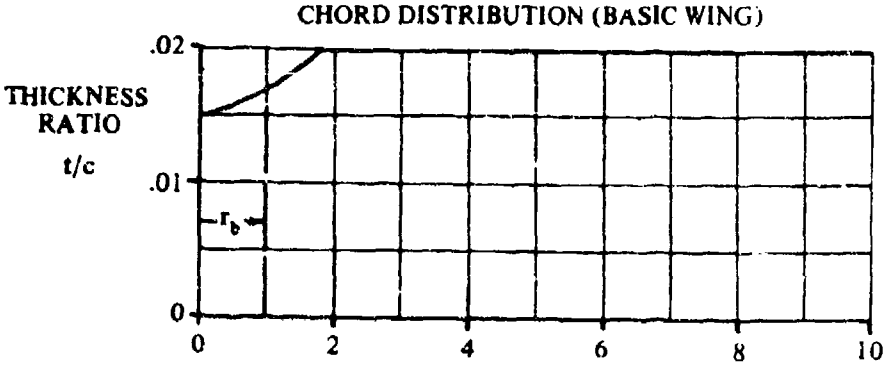
$$K = \frac{c(c - x_2)}{x_1 x_3} = \frac{1\,(1 - 0.3)}{(0.4)\,(0.3)} = 5.833$$

$(t/c)_{eff}$

The thickness distribution of the actual wing and the chord distribution of the basic wing are shown in sketch (h).



CHORD DISTRIBUTION (BASIC WING)



SEMISPAN STATION, y (in.)

THICKNESS DISTRIBUTION (ACTUAL PLANFORM)

SKETCH (h)

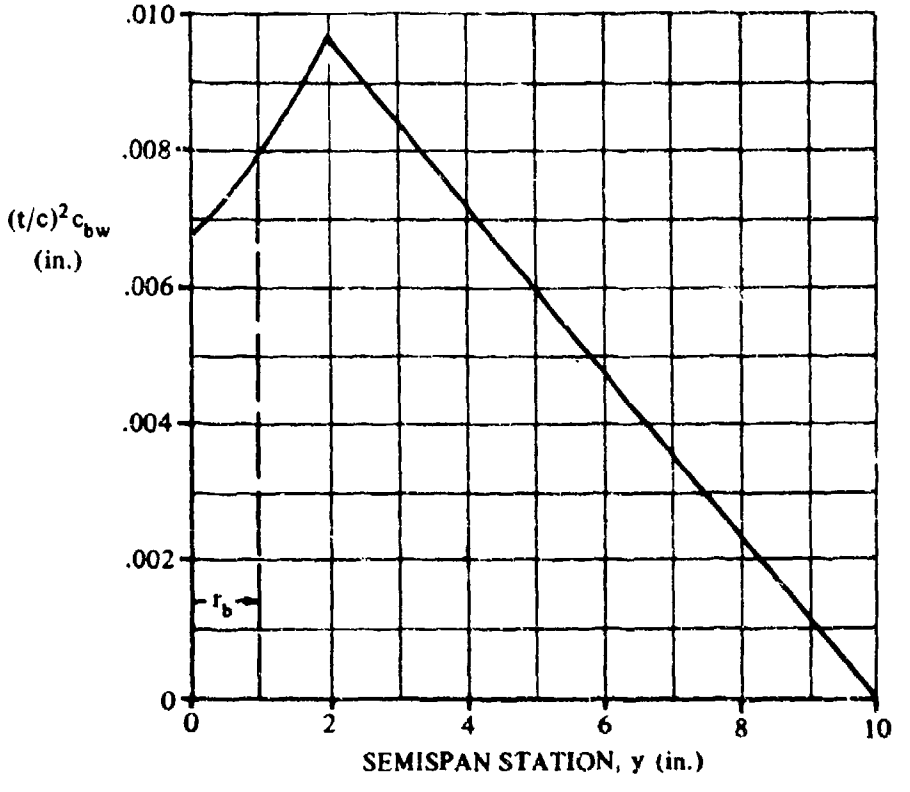
Sketch (i) shows $(t/c)^2\ c_{bw}$ versus spanwise position. Graphical integration of this curve gives

$$\int_{r_b}^{b/2} \left(\frac{t}{c}\right)^2 c_{bw}\ dy = 0.0474 \text{ sq in.}$$

$$\left(\frac{t}{c}\right)^2_{eff} = \frac{\int_{r_b}^{b/2} \left(\frac{t}{c}\right)^2 c_{bw}\ dy}{1/2\ (S_{bw})_e} \quad \text{(equation 4.3.3.1-j')}$$

$$= \frac{0.0474}{1/2\,(244.26)} = 0.000388$$

$$\left(\frac{t}{c}\right)_{eff} = 0.0197$$



INTEGRAND FOR DETERMINING $(t/c)_{eff}$ FOR WING OF SAMPLE WAVE-DRAG CALCULATION

SKETCH (i)

$\beta \cot \Lambda_{LE} = (2.807)\,(\cot 70^{o}) = 1.022$ (supersonic leading edge)

$$\left(C_{D_w}\right)_w = \frac{K}{\beta}\left(\frac{t}{c}\right)^2_{eff} \frac{(S_{bw})_e}{S_{ref}} \quad \text{(equation 4.3.3.1-h)}$$

$$= \left(\frac{5.833}{2.807}\right)(0.0197)^2 \frac{244.26}{301.55}$$

$$= 0.00065 \quad \text{(based on } S_{ref})$$

Determine the body contribution.

Skin-friction-drag coefficient

$R_\ell = (1.741 \times 10^6)(\ell_B) = (1.741 \times 10^6)(40) = 6.964 \times 10^7$

$\ell/k = \infty$, read $(C_f)_B$ at calculated R_ℓ

$(C_f)_B = 0.00139$ (figure 4.1.5.1-26)

Wave-drag coefficients (method 2, paragraph C, Section 4.2.3.1)

Forebody

$\beta/f_N = \dfrac{2.807}{6.0} = 0.468$; $K_N = 1.005$ (figure 4.2.3.1-63)

$C_{D_{N_2}} \left[f_N^2 + \dfrac{1}{4}\right] K_N = 0.985$ (figure 4.2.3.1-61)

$C_{D_{N_2}} = \dfrac{0.985}{(36 + 0.25)(1.005)} = 0.0270$ (based on S_B)

Afterbody

$\dfrac{d_b}{d} = 1.0$; $C_{D_A} = 0$ (figure 4.2.3.1-64)

Nose bluntness

$C_{D_{N_1}} = 0$ (no bluntness)

Afterbody interference-drag coefficient

$\dfrac{d_b}{d} = 1.0$; $C_{D_{A(NC)}} = 0$ (figure 4.2.3.1-44a)

Base-drag coefficient

$C_{D_b} = 0.098$ (figure 4.2.3.1-60) (based on S_B)

$\left(C_{D_0}\right)_B = (C_f)_B \dfrac{S_S}{S_B} + C_{D_{N_2}} + C_{D_A} + C_{D_{A(NC)}} + C_{D_{N_1}} + C_{D_b}$ (equation 4.2.3.1-h)

$= (0.00139)(72.0) + 0.0270 + 0 + 0 + 0 + 0.098$

$= 0.225$ (based on S_B)

Solution:

$$C_{D_0} = \left(C_{D_0}\right)_W + \left(C_{D_0}\right)_B \frac{S_B}{S_{ref}} \quad \text{(equation 4.3.3.1-d)}$$

$$= \left(C_{D_f} + C_{D_w}\right)_W + \left(C_{D_0}\right)_B \frac{S_B}{S_{ref}}$$

$$= 0.00256 + 0.00065 + (0.225)\ \frac{3.14}{301.55}$$

$$= 0.00555 \text{ (based on } S_{ref})$$

The test value from reference 15, corrected to remove base drag, is $C_{D_0} = 0.0046$. The corresponding calculated value is given by

$$C_{D_0} = 0.00555 - C_{D_b} \frac{S_B}{S_{ref}}$$

$$= 0.00555 - 0.00102$$

$$= 0.00453 \text{ (based on } S_{ref})$$

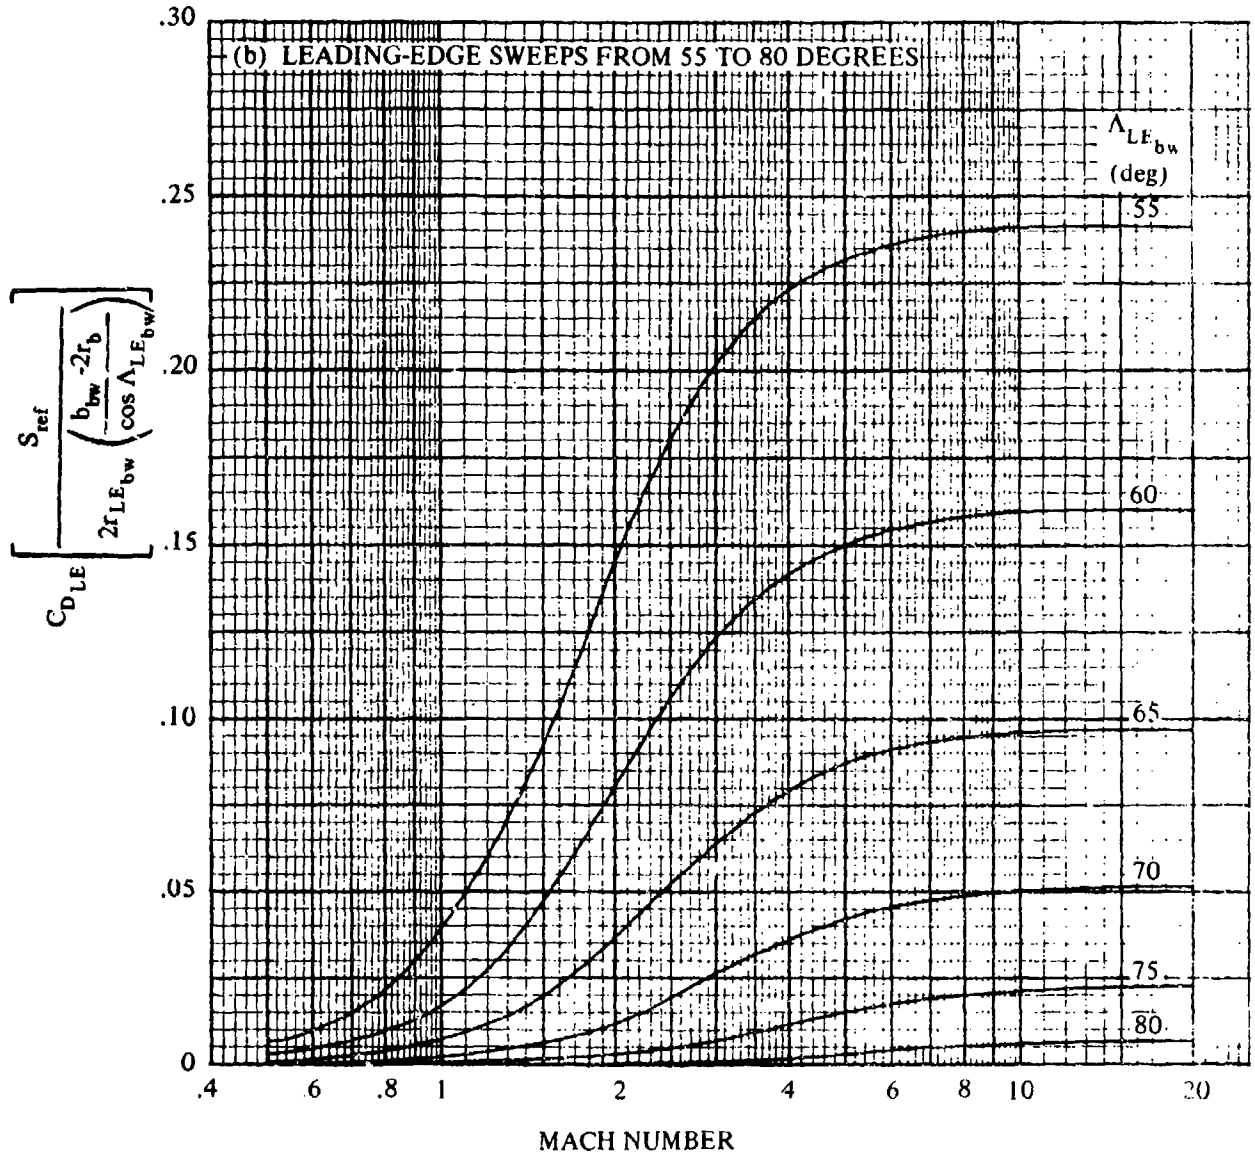

FIGURE 4.3.3.1-38 (CONTD)

4.3.3.2 WING-BODY DRAG AT ANGLE OF ATTACK

Determination of wing-body or tail-body drag at angle of attack is more an art than a science. Little is known concerning the wing-body aerodynamic interferences that occur at angle of attack. These interferences are usually significant only during the detailed design of a configuration or for a configuration especially designed for minimum interference at a particular flight condition. The total drag of a wing-body configuration at angle of attack may be expressed in the form

$$(C_D)_{WB} = (C_{D0})_{WB} + (C_{DL})_{WB} \qquad 4.3.3.2\text{-a}$$

where $(C_{D0})_{WB}$ is the zero-lift drag and $(C_{DL})_{WB}$ represents the drag due to lift. The zero-lift drag of the wing-body configuration may be obtained by using the methods of Section 4.3.3.1. The same two methods for estimating the wing-body drag-due-to-lift term are presented in each speed regime of this section. The first method, taken from Reference 1, evaluates the wing-body configuration as a unit. The second method evaluates and combines the isolated drag due to lift of the wing and of the body.

The primary advantage of Method 1 is its consideration of camber effects and its applicability to the high-lift region, i.e., beyond the parabolic drag region. However, its application is restricted to fighter-type aircraft with straight-tapered planforms.

Because of the empirical nature of Method 1 (values for the regression coefficients), exact solutions are available only at the following Mach numbers: 0.6, 0.7, 0.8, 0.9, 0.95, 1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 2.0, and 2.5. At other Mach numbers interpolation is necessary. For the low-speed regime, the M = 0.6 values can be used, but only as an approximation. The solutions at Mach numbers 1.0 and 2.5 should be used cautiously, because of the somewhat limited amount of test data used in the determination of the regression coefficients.

A. SUBSONIC

Two different methods are presented for evaluating the total drag of a wing-body configuration. The first method is restricted to fighter-type aircraft with straight-tapered planforms. The second method is general and may be applied to both straight-tapered planforms and non-straight-tapered planforms, including double-delta, cranked, and curved wings.

The general categories of non-straight-tapered wings are illustrated in Sketch (a) of Section 4.1.3.2, while the wing-geometry parameters are presented in Section 2.2.2.

For Mach numbers less than 0.6 and values within the parabolic drag region (generally for $C_L < 0.4$ or 0.5), Method 2 should be used because of the limitation of Method 1 for Mach numbers below 0.6.

DATCOM METHOD

Method 1

This method was developed in Reference 1 for fighter-type aircraft by using the linear regression analysis of mathematical statistics. In general, a regression analysis involves the study of a group of variables to determine their effect on a given parameter. In this case, multidimensional least-squares curve fits were used to relate linearly the incremental drag due to lift of a wing-body configuration

to certain nondimensional geometric parameters. The result of this work is presented below in Equation 4.3.3.2-b, a purely empirical equation based on the various total-wing-planform geometric parameters and Reynolds number. For more detailed information regarding the analysis, the reader is referred to Reference 1.

The regression coefficients given in Table 4.3.3.2-D, as a function of Mach number and angle of attack, are not those presented in Reference 1. Those in Table 4.3.3.2-D are a more recent and improved version obtained from the authors of Reference 1.

An unfortunate feature of this method is the lack of physical appreciation of where the parabolic drag region ends; i.e., where separation effects become prominent. A second method, called the semiempirical method, which provides a physical appreciation of the flow conditions, is also presented in Reference 1. The semiempirical method is structured to consider the following various flow conditions: attached flow, initially contained separated or mixed flow, and major flow separation occurring after the initially contained separated or mixed flow. The semiempirical method is somewhat more difficult to apply, while its accuracy is approximately the same as that of Method 1 presented herein. For the details regarding the application of the semiempirical method, the reader is referred to Reference 1.

It is advisable to restrict the applicability of Method 1 to the range of geometric parameters of the test data used in the formulation of the regression coefficients. If the method is used for configurations that exceed the range of test data, the results should be applied with caution. The test data used in the formulation of the regression coefficients have geometric parameters within the following limits:

aspect ratio, A	1.6 to 6.0
taper ratio, λ	0 to 1
twist, θ	0 to -9.4^{o}
leading-edge radius, LER/$\bar{c}$	0 to 0.015
thickness, t/$\bar{c}$	0.025 to 0.10
NACA camber, $(y_c)_{max}/\bar{c}$	0 to 0.0263
conical-camber design lift coefficient, C_{L_d}	0 to 0.45
forebody fineness ratio, ℓ_N/d	2.2 to 8.4
afterbody fineness ratio, ℓ_A/d	0.3 to 5.6
leading-edge sweep, Λ_{LE}	0 to 70^{o}
Reynolds number, R_ℓ	0.8×10^6 to 8×10^6

Equation 4.3.3.2-b below enables the user to calculate the drag due to lift as a function of angle of attack and Mach number. When a series of points are calculated to define the drag due to lift versus angle of attack, it becomes necessary to use discretion and fair the best possible curve through the points. This is necessary since some values at high angles of attack do not describe a smooth continuous curve.

This method is not limited to bodies of revolution; however, no attempt is made to account for the effects of noncircular bodies. If it becomes necessary to analyze a noncircular body in combination with a wing, it is suggested that an equivalent body of revolution be used, i.e., a body of revolution with the same cross-sectional area.

The drag due to lift at a given angle of attack of a wing-body configuration, based on the area of the basic straight-tapered wing, is given by

$$(C_{D_L})_{WB} = B_0 + B_1\left(\frac{1}{A}\right) + B_2 A + B_3(\tan \Lambda_{LE})^{1/2} + B_4(t/\bar{c}) + B_5\left(\frac{\ell_N}{d}\right) + B_6\left(\frac{\ell_A}{d}\right) + B_7 \lambda$$

$$+ B_8\lambda^2 + B_9\lambda^3 + B_{10}(T_R) + B_{11}\left(\frac{LER}{\bar{c}}\right) + B_{12}\theta + B_{13}\left[\frac{(y_c)_{max}}{\bar{c}}\right] + B_{14}\, C_{L_d}$$

$$+ B_{15} R_\ell \qquad \text{4.3.3.2-b}$$

where

$B_0, B_1, \ldots B_{15}$ are the regression coefficients as a function of Mach number and angle of attack obtained from Table 4.3.3.2-D.

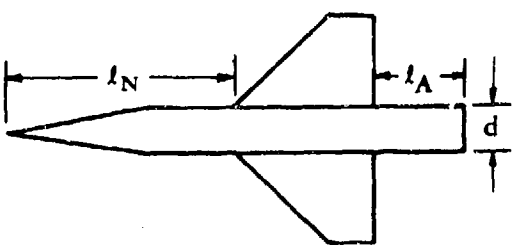
A is the total wing aspect ratio.

Λ_{LE} is the sweep of the leading edge.

$t/\bar{c}$ is the wing thickness ratio at the mean aerodynamic chord.

$\frac{\ell_N}{d}$ is the nose and forebody fineness ratio (see Sketch (a)).

$\frac{\ell_A}{d}$ is the afterbody fineness ratio taken at the afterbody wing-body juncture (see Sketch (a)).



SKETCH (a)

λ is the wing taper ratio.

T_R is the transition indicator; 0 for no transition strips and 1 for transition strips or flight test.

$\frac{LER}{\bar{c}}$ is the ratio of the leading-edge radius to the mean aerodynamic chord taken at the mean aerodynamic chord.

θ is the wing twist between the root and tip sections in radians, negative for washout (see Figure 5.1.2.1-30b).

$\frac{(y_c)_{max}}{\bar{c}}$ is the NACA camber in the form of a ratio of the maximum ordinate of the mean line to the airfoil chord taken at the mean aerodynamic chord.

C_{L_d} is the conical camber design lift coefficient for a M = 1.0 design with the designated camber ray line intersecting the wing trailing edge at 0.8 b/2. (For more details see Reference 2.) If the wing does not have a conical-camber design, the value of C_{L_d} is zero.

R_ℓ is the Reynolds number based on the mean aerodynamic chord. For Reynolds numbers in excess of 8×10^6, the value of 8×10^6 should be used.

An indication of the accuracy of Method 1 can be obtained from Table 4.3.3.2-A. This table contains a comparison of test values with results calculated by using this method for wing-body configurations without camber. The test data used in this comparison are taken from Table 4.1.5.2-A and some have been used in the determination of the regression coefficients.

Method 2

This method evaluates and combines the isolated drag due to lift of the wing and of the body. The limitations of the method are those of Sections 4.1.5.2 and 4.2.3.2. The method is not applicable to generalized wing-body configurations with arbitrary body shapes. If it becomes necessary to analyze a noncircular body in combination with a wing, it is suggested that an equivalent body of revolution be used, i.e., a body of revolution with the same cross-sectional area. The method is applicable only for wing lift coefficients up to the critical lift coefficients for configurations having straight-tapered wings; whereas, for non-straight-tapered wings the method may be applied to configurations over a wide range of lift coefficients (see Paragraph A, Section 4.1.5.2).

The drag due to lift of a wing-body configuration is given by

$$(C_{D_L})_{WB} = (C_{D_L})_W + [C_D(\alpha)]_B \frac{(S_B)_{ref}}{S_W} \qquad 4.3.3.2\text{-c}$$

where

$(C_{D_L})_W$ is the drag due to lift of the wing, obtained from Paragraph A of Section 4.1.5.2 and based on the total wing area.

$[C_D(\alpha)]_B$ is the body drag due to angle of attack, obtained from Paragraph A of Section 4.2.3.2 and based on the maximum body frontal area.

$\frac{(S_B)_{ref}}{S_W}$ is the ratio of the body reference area (maximum body frontal area) to the total wing area.

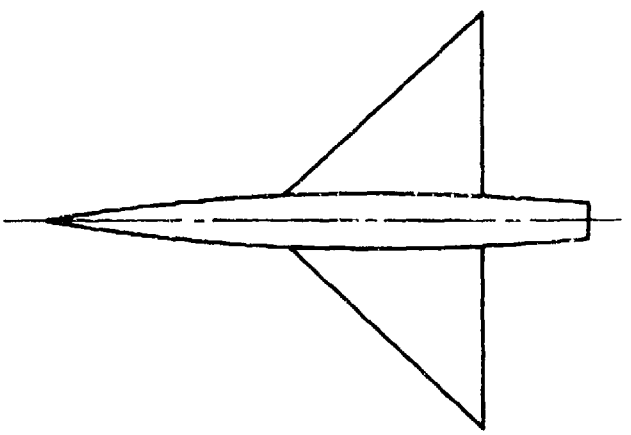
No substantiation is presented for this method. However, substantiation tables for the wing contribution are presented in Section 4.1.5.2 for straight-tapered and non-straight-tapered planforms.

Sample Problems

The same wing-body configurations will be evaluated for both Methods 1 and 2 to enable a comparison of their application to be made.

1. Method 1

Given: The straight-tapered wing-body configuration of Reference 3.



Wing Characteristics:

$A = 4.0$ $\quad \lambda = 0$ $\quad t/c = 0.03$ $\quad \Lambda_{LE} = 45^{o}$

$\theta = 0$ $\quad$ No camber, $\dfrac{(y_c)_{max}}{\bar{c}} = 0$ $\quad C_{L_d} = 0$

3-percent-thick biconvex airfoil with elliptic nose

$$\frac{LER}{\bar{c}} = 0.00045$$

Body Characteristics:

$$\frac{\ell_N}{d} = 4.28 \qquad \frac{\ell_A}{d} = 2.141$$

Additional Characteristics:

$M = 0.61$ $\quad R_{\ell} = 4.20 \times 10^{6}$ $\quad$ No transition strips, $T_R = 0$

Compute the drag due to lift for the above configuration at an angle of attack of 10^{o}.

The regression coefficients below are obtained from Table 4.3.3.2-D at M = 0.6.

Regression Coefficient	Value Table 4.3.3.2-D
B_0	0.12873
B_1	–0.05227
B_2	0.00855
B_3	–0.00826
B_4	–0.69952
B_5	–0.00295
B_6	–0.00487
B_7	0.14051
B_8	–0.28982
B_9	0.16952
B_{10}	–0.00215
B_{11}	2.27613
B_{12}	–0.34643
B_{13}	–0.52607
B_{14}	–0.09097
B_{15}	-0.00076×10^{-6}

Solution:

$$(C_{D_L})_{WB} = B_0 + B_1\left(\frac{1}{A}\right) + B_2 A + B_3(\tan \Lambda_{LE})^{1/2} + B_4(t/\bar{c}) + B_5\left(\frac{\ell_N}{d}\right) + B_6\left(\frac{\ell_A}{d}\right) + B_7\lambda$$

$$+ B_8\lambda^2 + B_9\lambda^3 + B_{10}T_R + B_{11}\left(\frac{LER}{\bar{c}}\right) + B_{12}\theta + B_{13}\left[\frac{(y_c)_{max}}{\bar{c}}\right]$$

$$+ B_{14}C_{L_d} + B_{15}R_\ell \qquad \text{(Equation 4.3.3.2-5)}$$

$$C_{D_L} = 0.12873 - 0.05227\left(\frac{1}{4}\right) + 0.00855(4) - 0.00826(1)^{1/2} - 0.69952(0.03)$$

$$- 0.00295(4.28) - 0.00487(2.141) + 0.14051(0) - 0.28982(0)^2 + 0.16952(0)^3$$

$$- 0.00215(0) + 2.27613(0.00045) - 0.34643(0) - 0.52607(0) - 0.09097(0)$$

$$- 0.00076 \times 10^{-6}(4.20 \times 10^6)$$

$$= 0.12873 - 0.01307 + 0.03420 - 0.00826 - 0.02099 - 0.01263 - 0.01043$$

$$+ 0.00102 - 0.00319$$

$$= 0.0954$$

The above procedure is used to generate the complete variation of C_{D_L} given below as a function of angle of attack. The comparison of test data with these predicted values and the predicted values from Method 2 are presented in Sketch (b), which follows the next sample problem.

α (deg)	$(C_{D_L})_{WB}$
0	0
1	0.00059
2	0.00196
3	0.00568
4	0.0115
6	0.0306
8	0.0598
10	0.0954
12	0.1356
14	0.1769
16	0.2196
18	0.2644

2. Method 2

Given: The same wing-body configuration used in Sample Problem 1, i.e., from Reference 3.

Wing Characteristics:

$A = 4.0$ $\quad \lambda = 0$ $\quad t/c = 0.03$ $\quad \Lambda_{LE} = 45^{o}$

$S_W = 2.425\ ft^2$ $\quad \bar{c} = 1.038\ ft$

$\theta = 0$ $\quad$ No camber $\quad \frac{LER}{\bar{c}} = 0.00045$

Body Characteristics:

$\ell_B = 46.93$ in. $\quad d = 4.76$ in. $\quad d_b = 2.589$ in.

$V_B = 0.2687\ ft^3$ $\quad V_B^{2/3} = 0.4164\ ft^2$

$f = \frac{\ell_B}{d} = 9.86$ $\quad r = 2.38 \left[1 - \left(1 - \frac{2x}{59.5} \right)^2 \right]^{3/2}$

Additional Characteristics:

$M = 0.61, \beta^2 = 0.6279$ $\quad R_{\ell_{MAC}} = 4.20 \times 10^6$ $\quad \kappa = 1.0$ (assumed)

Compute:

Wing Drag Due to Lift (Section 4.1.5.2)

$$\tan \Lambda_{c/2} = \tan \Lambda_{LE} - \frac{4}{A}\left[\frac{1}{2}\left(\frac{1-\lambda}{1+\lambda}\right)\right]$$

$$= 1.0 - \frac{4}{4}\left[\frac{1}{2}\left(\frac{1.0}{1.0}\right)\right]$$

$$= 0.5$$

$$\frac{A}{\kappa}[\beta^2 + \tan^2 \Lambda_{c/2}]^{1/2} = \frac{4}{1.0}[0.6279 + (0.5)^2]^{1/2} = 3.748$$

$$\frac{C_{L_\alpha}}{A} = 1.0 \text{ per rad} \qquad \text{(Figure 4.1.3.2-49)}$$

$$R_{\ell_{LER}} = 4.20 \times 10^6 \frac{0.00045\ \bar{c}}{\bar{c}} = 1.89 \times 10^3$$

$$R_{\ell_{LER}} \cot \Lambda_{LE} \sqrt{1 - M^2 \cos^2 \Lambda_{LE}} = (1.89 \times 10^3)(1.0)\sqrt{1 - (0.372)(0.7071)^2}$$

$$= 1.705 \times 10^3$$

$$\frac{A\lambda}{\cos \Lambda_{LE}} = \frac{(4.0)(0)}{(0.7071)} = 0$$

$R = 0.120$ (Figure 4.1.5.2-53a)

$$e = \frac{1.1\,(C_{L_\alpha}/A)}{R(C_{L_\alpha}/A) + (1-R)\pi} \qquad \text{(Equation 4.1.5.2-i)}$$

$$= \frac{1.1(1.0)}{0.120(1.0) + (1-0.120)\pi}$$

$$= 0.382$$

$$(C_{D_L})_W = \frac{C_L^{\,2}}{\pi Ae} + C_L \theta c_{\ell_\alpha} v + (\theta c_{\ell_\alpha})^2 w \qquad \text{(Equation 4.1.5.2-h)}$$

$$= \frac{C_L^{\,2}}{\pi(4.0)(0.382)}$$

C_L	$C_{D_L} = 0.209\ C_L^2$
0	0
0.05	0.00052
0.10	0.00209
0.15	0.00470
0.20	0.00836
0.25	0.01306
0.30	0.01881

0.40	0.03344
0.50	0.05225

Body Drag Due to Lift (Section 4.2.3.2)

$k_2 - k_1 = 0.94$ (Figure 4.2.1.1-20a)

$x_1 = 46.93$ (by inspection)

$$\frac{x_1}{\ell_B} = 1.0$$

$$\frac{x_o}{\ell_B} = 0.905 \qquad \text{(Figure 4.2.1.1-20b)}$$

$x_o = 42.47$ in.

$$(r)_{x_o} = 2.38 \left[1 - \left(1 - \frac{2(42.4)}{59.5}\right)^2\right]^{3/2} = 1.765 \text{ in.}$$

$S_o = \pi r^2 = \pi(1.765)^2 = 9.79$ in.^{2}

$$C_{L_\alpha} = \frac{2(k_2 - k_1)\, S_o}{V_B^{2/3}} \qquad \text{(Equation 4.2.1.1-a)}$$

$$= \frac{2(0.94)(9.79)}{(0.4164)144}$$

$= 0.307$ per rad

$\eta = 0.686$ (Figure 4.2.1.2-23a)

$M_c = M \sin \alpha$

The α range is approximately $0 \leqslant \alpha \leqslant 10^o$

M_c varies from 0.6(0) to 0.6(0.1736)

$0 \leqslant M_c \leqslant 0.104$

$c_{d_c} = 1.20$ (constant) (Figure 4.2.1.2-23b)

$$\int_{X_o}^{\ell_B} \eta \, r \, c_{d_c} \, dx = \int_{42.47}^{46.93} (0.686) \, r \, (1.20) \, dx$$

Assuming r varies linearly from x_o to ℓ_B

$$\int_{X_o}^{\ell_B} \eta \, r \, c_{d_c} \, dx = \int_{42.47}^{46.93} (0.686) \left(\frac{1.765 + 1.295}{2} \right) (1.20) dx$$

$$= 1.26(46.93 - 42.47)$$

$$= 5.62 \text{ sq in.} = 0.0390 \text{ sq ft}$$

$$C_D(\alpha) = \frac{k_2 - k_1}{V_B^{2/3}} 2 \alpha^2 S_o + \frac{2 \alpha^3}{V_B^{2/3}} \int_{x_o}^{\ell_B} \eta \, r \, c_{d_c} \, dx \qquad \text{(Equation 4.2.3.2-b)}$$

$$= 0.307 \alpha^2 + \frac{2 \alpha^3}{0.4164} (0.0390)$$

$$= 0.307 \alpha^2 + 0.187 \alpha^3$$

Equation 4.2.3.2-b becomes

$$[C_D(\alpha)]_B \frac{S_{B_{ref}}}{S_W} = (0.307 \alpha^2 + 0.187 \alpha^3) \frac{V_B^{2/3}}{S_W}$$

$$= (0.307 \alpha^2 + 0.187 \alpha^3) \frac{0.4164}{2.425}$$

$$= 0.0527 \alpha^2 + 0.0321 \alpha^3$$

$(C_{L_\alpha})_W = (C_{L_\alpha}/A) \, A = (1.0)(4.0) = 4.0$ per rad

(1)	(2)	(3)	(4)	(5)

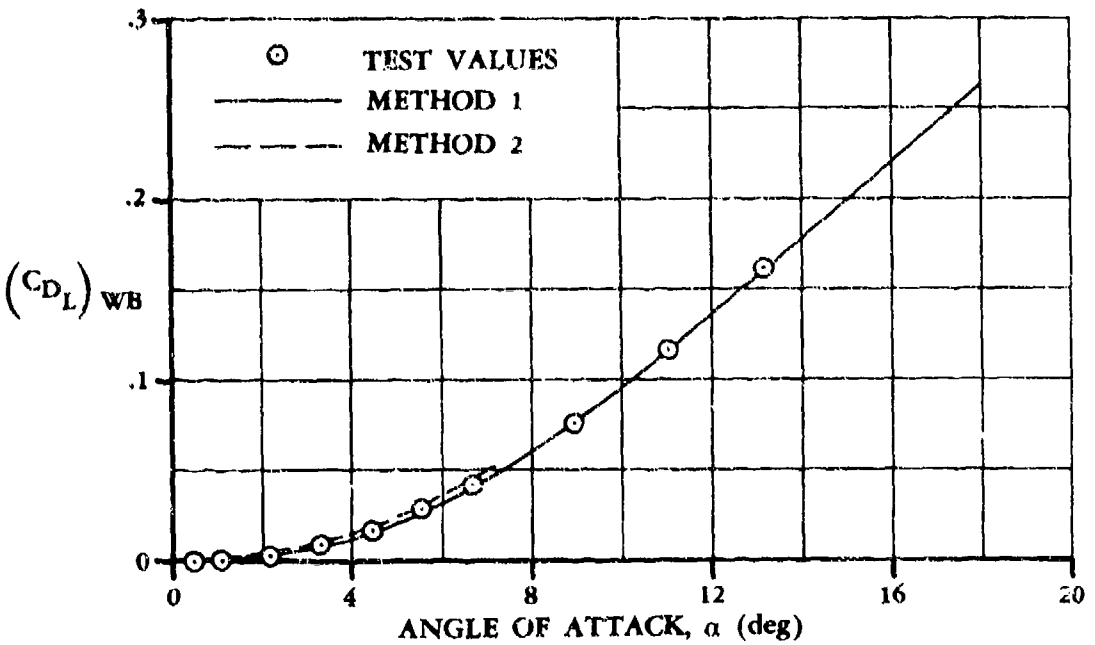
These calculated results are compared with the calculated results from Method 1 and the test values from Reference 3 in Sketch (b).

*This approximation assumes a zero lift value of zero.



SKETCH (b)

B. TRANSONIC

The comments presented in the discussion preceding Paragraph A are applicable here.

DATCOM METHODS

At transonic speeds the methods described in Paragraph A may be applied. Both methods are restricted to straight-tapered-wing configurations. Method 1 may be applied in the high-lift region; while Method 2 is restricted to the parabolic-drag region.

An indication of the accuracy of Method 1 can be obtained from Table 4.3.3.2-B. This table contains a comparison of test values with results calculated by using this method for wing-body configurations without camber.

Sample Problem

No sample problem is presented for Method 1 because its application is identical to that in the subsonic speed regime.

Method 2

Given: A wing-body configuration of Reference 2 designated 45-series.

Wing Characteristics:

$A = 3.0$ $\quad \lambda = 0.40$ $\quad b_W = 10.8$ in. $\quad \Lambda_{LE} = 45^o$

$\Lambda_{c/2} = 35.54^o$ $\quad (t/c)_{av} = 0.045$ $\quad S_W = 38.889$ sq in. $\quad$ Round-nosed airfoil

Additional Characteristics:

$\frac{S_b}{S_W} = 0.0278$ $\quad 0 \le C_L \le 0.50$ $\quad M = 1.02;\ \beta = 0.20$ $\quad \kappa = 1.0$ (assumed)

Compute:

Wing Drag Due to Lift (Section 4.1.5.2)

$$\left(t/c\right)^{1/3} = 0.3557$$

$$\left(t/c\right)^{2/3} = 0.1265$$

$$A\left(t/c\right)^{1/3} = 3(0.3557) = 1.067$$

$$A \tan \Lambda_{LE} = 3.0$$

$$\frac{M^2 - 1}{(t/c)^{2/3}} = \frac{0.0404}{0.1265} = 0.319$$

$$\left(\frac{t}{c}\right)^{-1/3} \frac{C_{D_L}}{C_L{}^2} = 0.590 \quad \text{(Figure 4.1.5.2-55b, interpolated)}$$

$$\frac{C_{D_L}}{C_L{}^2} = 0.590\,(0.3557) = 0.210$$

SKETCH (c)

C. SUPERSONIC

The comments presented in the discussion preceding Paragraph A are applicable here.

DATCOM METHODS

At supersonic speeds the methods described in Paragraph A may be applied. Method 1 is restricted to straight-tapered planforms; while Method 2 may be applied to either straight-tapered or non-straight-tapered wings. An indication of the accuracy of Method 1 can be obtained from Table 4.3.3.2-C. This table contains a comparison of test values with results calculated by using this method for wing-body configurations without camber.

Sample Problem

No sample problem is presented for Method 1 because its application is identical to that in the subsonic speed regime.

Method 2

Given: The wing-body configuration of Reference 5.

Wing Characteristics:

$A = 3.50$ $b_W = 24$ in. $\lambda = 0.20$ $\Lambda_{LE} = 51.6^o$

$\ell = 17.44$ in. $S_W = 164.64$ sq in. $\delta_\perp = 8.4^o$

Airfoil: 6-percent-thick hexagonal section with maximum thickness at c/3 (sharp-nosed airfoil)

Additional Characteristics:

$M = 2.01$; $\beta = 1.744$ $\qquad S_b = 12.57$ sq in.

$0 \leq C_L \leq 0.40$ $\qquad S_p = 154$ sq in.

Compute:

Wing Drag Due to Lift (Section 4.1.5.2)

$$\frac{\beta b_W}{2\ell} = \frac{1.744\,(24)}{2\,(17.44)} = 1.20$$

$$p = \frac{S_W}{b_W \ell} = \frac{164.64}{24\,(17.44)} = 0.393$$

$$\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p} = 1.29 \qquad \text{(Figure 4.1.5.2-58)}$$

$$\frac{C_{D_L}}{C_L^2} = \left[\pi A \frac{C_{D_L}}{C_L^2} \frac{p}{1+p}\right] \frac{1}{\pi A} \frac{1+p}{p} \qquad \text{(Equation 4.1.5.2-n)}$$

$$= 1.29 \left(\frac{1}{\pi(3.5)}\right)\left(\frac{1.393}{0.393}\right)$$

$$= 0.416$$

Body Drag Due to Lift (Section 4.2.3.2)

Wing C_{N_α} (Section 4.1.3.2)

$$\frac{\tan \Lambda_{LE}}{\beta} = \frac{1.262}{1.744} = 0.724$$

$$A \tan \Lambda_{LE} = 3.5\,(1.262) = 4.42$$

$$\beta\left(C_{N_\alpha}\right)_{theory} = 4.24 \text{ per rad} \quad \text{(Figure 4.1.3.2-56b)}$$

$$\left(C_{N_\alpha}\right)_{theory} = 4.24/1.744 = 2.\ldots \text{ per rad}$$

$$\frac{C_{N_\alpha}}{\left(C_{N_\alpha}\right)_{theory}} = 0.895 \quad \text{(Figure 4.1.3.2-60)}$$

$$C_{N_\alpha} = (2.43)\,(0.895) = 2.17 \text{ per rad}$$

$\left[C_D(\alpha)\right]_B$ (based on body base area)

$$\left[C_D(\alpha)\right]_B = 2\alpha^2 + c_{d_c}\frac{S_p}{S_b}\alpha^3 \quad \text{(Equation 4.2.3.2-g)}$$

$$\frac{S_p}{S_b} = \frac{154}{12.57} = 12.25$$

Solution:

Equation 4.3.3.2-a becomes

$$\left(C_{D_L}\right)_{WB} = \left(C_{D_L}\right)_W + \left[C_D(\alpha)\right]_B \frac{S_b}{S_W}$$

$$\frac{S_b}{S_W} = \frac{12.57}{164.64} = 0.0763$$

(1)	(2)	(3)	(4)
C_L	C_{D_L}	$[C_D(\alpha)]_B$ (based on S_b)	$(C_{D_L})_{WB}$ (2) + 0.0763 (3)

4.4 WING-WING COMBINATIONS AT ANGLE OF ATTACK (WING FLOW FIELDS)

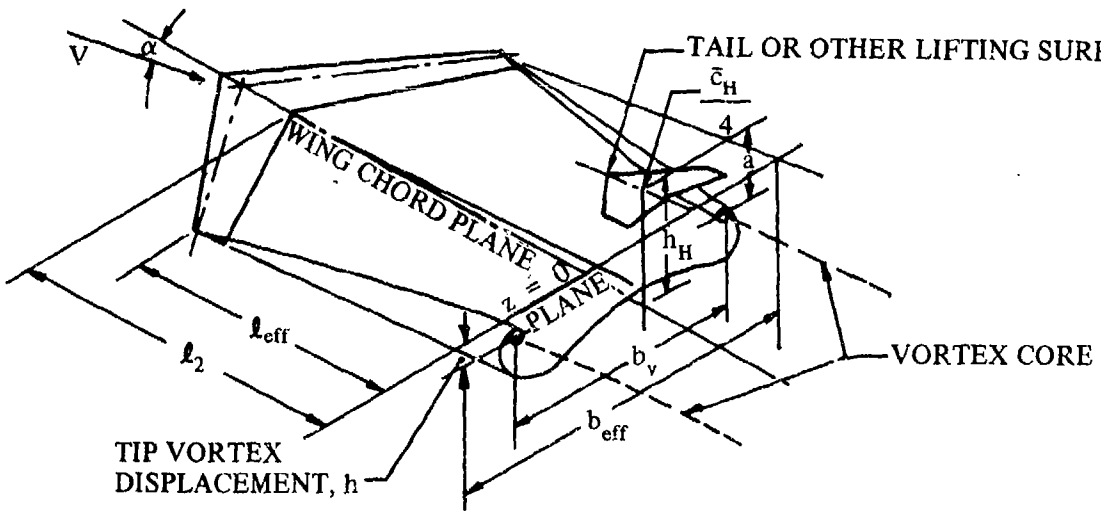
4.4.1 WING-WING COMBINATIONS AT ANGLE OF ATTACK

This section presents methods of estimating the properties of wing flow fields. The subsonic methods include the effects of flow direction (downwash) and dynamic-pressure ratio. The supersonic methods include the effects of downwash, dynamic-pressure ratio, and Mach number.

A. SUBSONIC

Downwash*

The downwash behind a wing in subsonic flow is a consequence of the wing-trailing-vortex system. The trailing-vortex system behind a swept wing is shown in Sketch (a). A vortex sheet is shed by the lifting wing, and the sheet is deflected downward by the bound or lifting vortex and the tip vortices, which comprise the vortex system. In general, the sheet is not flat, but the curvature near the wing midspan is usually relatively small. This is particularly true of straight wings of reasonably large aspect ratio, for which the central portion of the vortex sheet is extremely flat. Wings with considerable trailing-edge sweepback produce a vortex sheet that is bowed upward near the plane of symmetry.



SKETCH (a)

The tip vortices do not experience a vertical displacement as great as the displacement of the central portion of the vortex sheet. In general, they trail back comparatively close to the streamwise direction.

*This general discussion is essentially quoted from Reference 1.

Furthermore, as the vortex system proceeds downstream, the tip vortices tend to move inboard. Also, with increasing distance behind the wing, the trailing-sheet vorticity tends to be transferred to the tip vortices. The transfer of vorticity and inboard movement of the tip vortices takes place in such a fashion that the lateral center of gravity of the vorticity remains at a fixed spanwise location. When all of the vorticity is transferred from the sheet to the trailing vortices, the vortex system is considered to be fully rolled up, and, in a nonviscous fluid, the vortex system then extends unchanged to infinity.

Ahead of the longitudinal station for complete rollup, the spanwise downwash distribution is dependent upon the spanwise lift distribution of the wing. However, when the rollup is complete, the downwash angles for all wings of equal lift and equal effective span are identical. It is evident that the shape of the vortex sheet has a significant influence on the downwash experienced by a tail located in the flow field of a wing and that the tail location relative to the trailing vortices is very important. Since the tip vortices are somewhat above the vortex sheet, the downwash above the sheet is somewhat greater than the downwash beneath the sheet.

The tip vortices spring from the wing tips at angles of attack for which the flow is unseparated. However, wings with high sweepback angles tend to stall at the tips, and in many instances the tip vortices originate well inboard of the wing tip at high angles of attack. This phenomenon has a significant influence on the downwash.

The previous discussion has been concerned with wings that behave in a somewhat conventional manner at high angles of attack. Certain thin, highly swept wings have a significantly different flow pattern in the higher angle-of-attack range. These wings are characterized by a leading-edge separation vortex that lies above the surface of the wing. From its inception near the plane of symmetry, it moves outboard in the approximate direction of the wing leading edge and is finally shed in a streamwise direction near the wing tip. Reference 2 shows some interesting studies of the separation vortex. It is clear that the existence of this vortex has an important influence on the downwash.

For very low-aspect-ratio configurations or for canard configurations, the tip vortex from the forward panel may impinge directly on the aft surface. Reference 3 contains a method (presented as Method 3 herein) of estimating the lift acting on the aft panel for this type of configuration. The method assumes that the trailing vortices are shed at a spanwise station corresponding to the center of vorticity of the isolated panel. The vortex pair is then assumed to remain at this spacing for longitudinal distances at least beyond the aft panel. This spacing is also assumed to be constant as a function of angle of attack. In the vertical plane the vortex pair is assumed to trail in the free-stream direction. These assumptions are shown in Reference 3 to be not only convenient, but reasonable in the light of experimental data. With the position of the vortices determined and their strength calculated from the lift of the forward panel, the integrated lift on the aft panel can be computed by means of strip theory. Because the theoretical vortex contains infinite velocities at its center, the method gives erroneous answers where the vortices trail very close to the aft panel. In reality the cores of the vortices revolve as solid bodies with zero tangential velocity at their centers.

Downwash Due to Flap Deflection

The downwash behind a wing is substantially modified by the deflection of trailing-edge flaps. This deflection creates an increase in the spanwise loading on the wing that increases the strength of the wing-trailing-vortex system. Consequently, the increased strength of the wing-trailing vortex produces an increase in the downwash angle.

At present, no theoretical methods exist that lend themselves to hand calculation for predicting the variation in downwash angle due to flap deflection. However, empirical curves are presented for estimating the variation in downwash angle due to deflection of plain or slotted flaps at small angles of attack at low subsonic speeds. The correlation parameters used to generate these curves are presented in Reference 4. The curve for slotted flaps is based on data from single- and double-slotted flap data.

Upwash

Upwash ahead of the wing is induced by the wing vortex system in a manner similar to that for downwash. A knowledge of flow fields beneath and ahead of a wing is sometimes required for the determination of forces and moments on nacelles or external stores or for the determination of inflow velocities into propellers of jet-engine intakes. Reference 3 contains charts for determining upwash about any straight-tapered swept or unswept wing. Because of their volume, these charts have not been included in the Datcom. Reference 5 contains a limited treatment for unswept wings only.

Dynamic-Pressure Ratio

The effectiveness of a lifting surface is directly proportional to the average dynamic pressure acting over that surface. A surface operating in the wake of an upstream surface therefore experiences a loss in effectiveness because of the reduced dynamic pressure. The decrease in dynamic pressure is caused by the loss of flow energy in the form of friction and separation drag of the forward surface; the greater the drag, the greater the pressure loss.

The wake, usually thin and intense at or near the trailing edge, spreads and decays with increasing distance downstream in such a manner that the integrated momentum across the wake at any station is constant. This type of wake, which is due to viscous effects, occurs at all speeds.

DATCOM METHODS

Subsonic Downwash

Three methods are presented below for estimating downwash characteristics. The first method is somewhat laborious, but enables the complete downwash curve to be estimated. The second method is accurate and expedient to use, but predicts only the downwash gradient. The third method is applicable only for configurations where the span of the forward surface is approximately equal to or less than that of the aft surface. Tables 4.4.1-A and -B present a data summary and substantiation for Methods 1 and 2,respectively, using the same test data.

Method 1

This method for estimating the downwash behind straight-tapered lifting wings at subsonic speeds is taken from Reference 1. The method is applicable to configurations in which the span of the wing is at least 1.5 times as large as that of the horizontal tail ($b/b_H \geq 1.5$). The basic approach is as follows (see Sketch(a)):

1. Determine the downwash in the plane of symmetry at the height of the vortex cores and at the longitudinal station of the quarter-chord point of the horizontal-tail mean aerodynamic chord.

2. Correct this value for the horizontal-tail height above or below the trailing vortices.

3. Evaluate the effect of horizontal-tail span by relating the average downwash at the tail to the downwash determined in the second step.

The downwash gradient $\frac{\partial \epsilon}{\partial \alpha}$ at the trailing edge of a wing is unity. The value at a distance infinitely far downstream is given by (Reference 6) as

$$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_{\infty} = \frac{2\ (57.3)}{\pi A}\ C_{L_\alpha} \qquad 4.4.1\text{-a}$$

If these two values are known, the downwash gradient for any intermediate longitudinal position can be found by means of lifting-line theory.

For straight wings that have tip stall or thin swept wings that shed the leading-edge vortices inboard of the wing tips, the effective wing aspect ratio is considerably less than the geometric aspect ratio. An effective aspect ratio based on induced-drag considerations has been determined for these wings.

The maximum downwash at the plane of symmetry occurs at the intersection of the plane of symmetry with the plane containing the tip vortices. The ratio of the downwash at the plane of symmetry at a height a above or below this intersection to the downwash at the height of the vortex cores $\frac{\epsilon}{\epsilon_v}$ is given by

$$\frac{\epsilon}{\epsilon_v} = \frac{1}{1 + \left(\frac{2a}{b_v}\right)^2} \qquad 4.4.1\text{-b}$$

where b_v is the span of the wing-tip vortices at the quarter-chord point of the horizontal-tail MAC, and a is the height determined by means of Equation 4.4.1-c or 4.4.1-d (see Sketch (a)).

Because of the spanwise variation of downwash, the effective downwash acting on a horizontal tail is different from that at the plane of symmetry. A correction for tail-span effect is presented from Reference 1; it is based on the assumption that the vortices are essentially rolled up at the longitudinal tail station. This is a valid assumption except for cases where the core of the vortex approaches the surface of the tail. It should be noted that the vortex rolls up in a shorter distance as the angle of attack is increased. This is fortunate, because downwash effects become increasingly important at the higher angles of attack.

The subsonic downwash is obtained from the procedure outlined in the following steps:

Step 1. The effective wing aspect ratio A_{eff} and the effective wing span b_{eff} are obtained from Figure 4.4.1-66 as a function of the wing angle-of-attack parameter $\frac{\alpha - \alpha_0}{\alpha_{C_{L_{max}}} - \alpha_0}$. α is the selected wing angle of attack and α_0 and $\alpha_{C_{L_{max}}}$ may be estimated from Sections 4.1.3.1 and 4.1.3.4, respectively.

Step 2. The downwash gradient $\left(\frac{\partial \epsilon}{\partial \alpha}\right)_v$ in the plane of symmetry at the height of the vortex core is obtained for any longitudinal station, e.g., the quarter-chord point of the MAC of the horizontal tail, from Figure 4.4.1-67. This figure is entered with $2\frac{\ell_2}{b}$ and A_{eff}, where ℓ_2 is the distance measured parallel to the wing root chord, between the aft end of the wing root chord and the quarter-chord point of the MAC of the horizontal tail (see Sketch (a)).

Step 3. Determine the vertical position of the vortex core (see Sketch (a)). This depends upon the type of wing flow separation as determined from Figure 4.4.1-68a.

For trailing-edge separation

$$a = h_H - \ell_{eff}\left(\alpha - \frac{0.41\,C_L}{\pi A_{eff}}\right) - \frac{b_{eff}}{2}\tan\Gamma \qquad 4.4.1\text{-c}$$

For leading-edge separation

$$a = h_H - (\ell_2 + \ell_3)\left(\alpha - \frac{0.41\,C_L}{\pi A_{eff}}\right) - \frac{b_{eff}}{2}\tan\Gamma \qquad 4.4.1\text{-d}$$

where

C_L is the wing-alone lift coefficient obtained from test data or estimated by using the straight-tapered-wing method of Paragraph A of Section 4.1.3.3.

a is the distance from the quarter-chord point of the MAC of the horizontal tail to the plane of the tip vortex cores, positive for the horizontal tail MAC above the plane of the tip vortex cores.

h_H is the height of the horizontal-tail MAC quarter-chord point above or below the plane of the wing root chord, measured in the plane of symmetry and normal to the extended wing root chord, positive for the horizontal tail MAC above the plane of the wing root chord.

ℓ_{eff} is the distance measured parallel to the wing root chord, between the effective wing-tip quarter-chord point and the horizontal-tail MAC quarter-chord point.

ℓ_3 is the distance measured parallel to the plane of symmetry, between the forward end of the wing MAC and the aft end of the wing root chord, and ℓ_2 is defined in Step 2. In both Equations 4.4.1-c and 4.4.1-d, α is in radians, and the values of ℓ_{eff}, ℓ_2, and ℓ_3 are positive.

Step 4. Determine the span of the vortices at the longitudinal location of the quarter-chord point of the horizontal-tail MAC by

$$b_v = b_{eff} - \left(b_{eff} - b_{v_{ru}}\right)\left(\frac{2\ell_{eff}}{b\xi_{ru}}\right)^{1/2} \qquad 4.4.1\text{-e}$$

where

$$b_{v_{ru}} = [0.78 + 0.10\,(\lambda - 0.4) + 0.003\,\Lambda_{c/4}]\,b_{eff} \quad (\Lambda_{c/4} \text{ in degrees}) \qquad 4.4.1\text{-f}$$

$$\xi_{ru} = \frac{0.56\,A}{C_L}$$

Step 5. By using the parameters calculated in the above steps, obtain the average downwash gradient acting on the tail $\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)$ from Figure 4.4.1-68b.

Step 6. The procedures of Steps 1 through 5 are for low speeds. For higher subsonic Mach numbers the downwash gradient is given by

$$\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_M = \left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_{\substack{\text{low} \\ \text{speed}}} \frac{\left(\frac{dC_L}{d\alpha}\right)_M}{\left(\frac{dC_L}{d\alpha}\right)_{\substack{\text{low} \\ \text{speed}}}} \qquad 4.4.1\text{-g}$$

where

$\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_{\substack{\text{low} \\ \text{speed}}}$ is obtained by using Steps 1 through 5.

$\left(\frac{dC_L}{d\alpha}\right)_M$ and $\left(\frac{dC_L}{d\alpha}\right)_{\substack{\text{low} \\ \text{speed}}}$ are given by the straight-tapered wing methods of Paragraph A of Sections 4.1.3.2 or 4.1.3.3, depending upon the Mach number and angle of attack.

Step 7. Determine the average downwash acting on the horizontal tail by integrating the average downwash gradient from Step 5 or 6, i.e.,

$$\bar{\epsilon} = \int_{\alpha_0}^{\alpha} \frac{\partial \bar{\epsilon}}{\partial \alpha}\, d\alpha$$

A sample problem illustrating the use of this method is presented on Pages 4.4.1-12 through 4.4.1-16. The method will predict the downwash angles at the horizontal tail with accuracy acceptable for preliminary-design purposes for most configurations. However, since the effect of tail span has been determined under the assumption that the vortices are essentially rolled up at the tail location, caution should be used in applying the method if the tail length is short and the tail plane is near the location of the vortex core height.

Not enough test data are available to substantiate the validity of the compressibility correction given by Equation 4.4.1-g.

Method 2

An empirical method for estimating the downwash gradient behind straight-tapered wings at subsonic speeds is taken from Reference 7. The method is restricted to the angle-of-attack range over which the variation of downwash angle is a linear function of angle of attack.

The average low-speed downwash gradient at the horizontal tail is given by

$$\frac{\partial \bar{\epsilon}}{\partial \alpha} = 4.44 \left[K_A K_\lambda K_H (\cos \Lambda_{c/4})^{1/2} \right]^{1.19} \qquad 4.4.1\text{-h}$$

where K_A, K_λ, and K_H are wing-aspect-ratio, wing-taper-ratio, and horizontal-tail-location factors obtained from Figures 4.4.1-69a, 4.4.1-69b, and 4.4.1-70, respectively. In Figure 4.4.1-70, ℓ_H is the distance measured parallel to the wing root chord, between the wing MAC quarter-chord point and the quarter-chord point of the MAC of the horizontal tail, and h_H is the position of the quarter-chord point of the horizontal tail MAC relative to the plane of the wing root chord as defined in Method 1.

At higher subsonic speeds the effect of compressibility is approximated by

$$\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_M = \left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_{\substack{\text{low} \\ \text{speed}}} \frac{\left(C_{L_\alpha}\right)_M}{\left(C_{L_\alpha}\right)_{\substack{\text{low} \\ \text{speed}}}} \qquad 4.4.1\text{-i}$$

where

$\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_{\substack{\text{low} \\ \text{speed}}}$ is obtained using Equation 4.4.1-h.

$\left(C_{L_\alpha}\right)_{\substack{\text{low} \\ \text{speed}}}$ and $\left(C_{L_\alpha}\right)_M$ are the wing lift-curve slopes at the appropriate Mach numbers, obtained by using the straight-tapered-wing method of Paragraph A of Section 4.1.3.2.

A comparison of low-speed test data with $\partial\epsilon/\partial\alpha$ calculated by this method is presented as Table 4.4.1-B. The ranges of geometric parameters of the test data are:

$$2.00 \leq A \leq 8.00$$

$$0 \leq \lambda \leq 1.625$$

$$3.4 \leq \Lambda_{c/4} \leq 56.5$$

$$-0.177 \leq \frac{2 h_H}{b} \leq 0.537$$

$$0.78 \leq \frac{2 \ell_H}{b} \leq 2.44$$

$$0.280 \leq \frac{b_H}{b} \leq 0.800$$

Since the tail-span effect has not been explicitly included in this method, the authority of the method outside the limits $0.280 \leq \frac{b_H}{b} \leq 0.800$ is unknown.

Not enough test data are available to substantiate the validity of the compressibility correction given by Equation 4.4.1-i.

Method 3

For configurations in which the span of the forward surface is approximately equal to or less than that of the aft surface, the following method, taken from Reference 3, is recommended.

Step 1. The spatial position of the trailing vortices is first determined relative to the aft surface. The lateral spacing is determined from Figure 4.4.1-71 as a function of the exposed forward-surface planform geometry. This spacing is invariant with longitudinal distance and angle of attack. The vertical position is determined by assuming that the vortex springs from the trailing edge at the previously determined lateral position and trails in the free-stream direction. The pertinent vertical dimension is the distance between the quarter-chord point of the MAC of the aft surface and the vortex as determined above.

Step 2. The vortex interference factor $I_{v_{W'(W'')}}$ is obtained from Figures 4.3.1.3-7a through 4.3.1.3-7ℓ as a function of the lateral and vertical vortex positions, determined in Step 1 above, and the geometry of the aft panel. (The primed notation refers to the forward panel and the double-primed notation refers to the aft panel.)

Step 3. The vortex interference factor so determined is used in Sections 4.5.1.1 and 4.5.1.2 to obtain the lift generated on the aft surface for complete wing-body-tail combinations.

The use of the sample problem on Page 4.4.1-16 as a guide is essential in applying this method.

Subsonic Downwash Due to Flap Deflection

The method for estimating the change in downwash due to deflection of plain or slotted flaps is based on the empirical curves presented in Figure 4.4.1-72. Tables 4.4.1-C and -D present a data summary and substantiation of the test data used to generate these empirical curves. The user is advised to exercise caution when evaluating a configuration with different geometric parameters from those appearing in Table 4.4.1-C.

To utilize Figure 4.4.1-72, the user obtains a value for $\frac{\Delta\epsilon\, A\lceil b_f/(b/2)\rceil}{\Delta C_L}$ based on the flap type and the ratio of tail height above the wing-chord plane to wing semispan $\frac{h_H}{b/2}$. The change in downwash angle $\Delta\epsilon$ is then

obtained by

$$\Delta\epsilon = \left\{\frac{\Delta\epsilon\, A[b_f/(b/2)]}{\Delta C_L}\right\} \frac{\Delta C_L}{A[b_f/(b/2)]}$$

where

A	is the wing aspect ratio.
$\frac{b_f}{b/2}$	is the ratio of flap span of one wing to wing semispan.
ΔC_L	is the lift increment due to flap deflection obtained from test data or Section 6.1.4.1.
b/2	is the wing semispan.
h_H	is the tail height above the wing-chord plane, positive up.

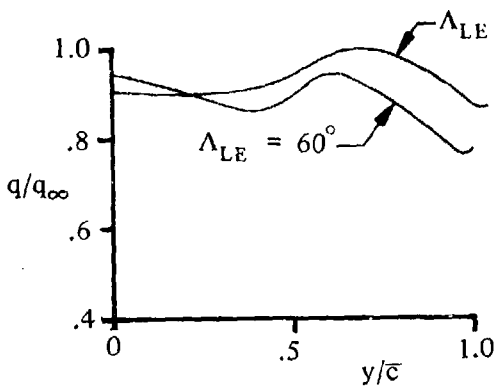
Subsonic Upwash

The upwash gradient $\frac{\partial \epsilon_u}{\partial \alpha}$ in the plane of symmetry of an unswept wing is presented as a function of the wing aspect ratio in Figure 4.4.1-73. This chart is from Reference 5.

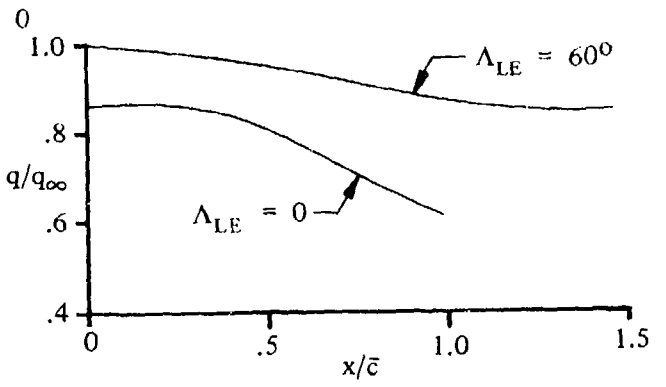
In Reference 3, the flow characteristics beneath a wing are calculated by assuming the wing to be represented by a multiple arrangement (both chordwise and spanwise) of horseshoe vortices and accounting for the effects of wing thickness distribution by using the appropriate singularity distribution in conjunction with simple sweep theory. The calculative procedures, together with the required design charts, are presented in Reference 3. Also presented are comparisons between detailed experimental flow fields around swept and unswept wing-fuselage combinations and wing-alone flow fields calculated by this method. The calculated results are qualitatively correct in all cases investigated.

Subsonic Dynamic-Pressure Ratio

This method for estimating the dynamic-pressure q/q_∞ at subsonic speeds and in the linear angle-of-attack range is based on the method presented in Reference 8, which relates the dynamic-pressure ratio to the drag coefficient of the wing. The method gives values of q/q_∞ at the plane of symmetry only. Actually, considerable variations in q/q_∞ can occur in both the spanwise and longitudinal directions. Sketches (b) and (c) show typical spanwise and longitudinal variations, respectively, of dynamic-pressure ratio for a straight wing and a 60° sweptback wing (from Reference 9). In general these data indicate that stronger spanwise deviations result when the wing is swept back, and stronger longitudinal deviations result when the wing is unswept.



SKETCH (b)



SKETCH (c)

In the linear angle-of-attack range, the ratio of the dynamic pressure in the plane of symmetry at some distance x aft of the wing-root-chord trailing edge to the free-stream dynamic pressure q/q_∞ is obtained from the procedure outlined in the following steps:

Step 1. Calculate the half-width of the wing wake by

$$\frac{z_w}{\bar{c}} = 0.68 \sqrt{C_{D_0}\left(\frac{x}{\bar{c}} + 0.15\right)} \qquad 4.4.1\text{-j}$$

where

x is the longitudinal distance measured along the wake center line from the wing-root-chord trailing edge, positive aft.

z_w is the half-width of the wake at any position x.

C_{D_0} is the wing zero-lift drag coefficient obtained from Paragraph A of Section 4.1.5.1.

Step 2. Calculate the downwash in the plane of symmetry at the vortex sheet (assumed to be the same location as the wake center line) by

$$\epsilon = \frac{1.62\, C_L}{\pi A} \text{ (radians)} \qquad 4.4.1\text{-k}$$

Step 3. Determine the vertical distance z from the vortex sheet to the point of interest (usually the quarter-chord point of the MAC of the horizontal tail) by

$$z = x \tan(\gamma + \epsilon - \alpha) \qquad 4.4.1\text{-}\ell$$

where γ is defined in Sketch (d).

Step 4. Determine the dynamic-pressure-loss ratio at the wake center $\left(\frac{\Delta q}{q}\right)_o$ by the empirical relation

$$\left(\frac{\Delta q}{q}\right)_o = \frac{2.42\,(C_{D_0})^{1/2}}{\frac{x}{\bar{c}} + 0.30} \qquad 4.4.1\text{-m}$$

Step 5. Determine the dynamic-pressure-loss ratio for points not on the wake center line by

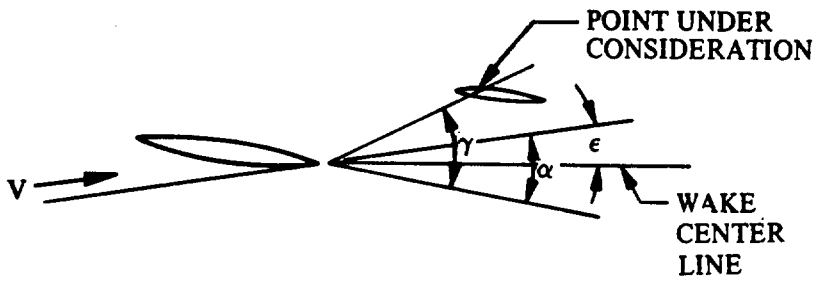
$$\frac{\Delta q}{q} = \left(\frac{\Delta q}{q}\right)_o \cos^2\left(\frac{\pi}{2}\,\frac{z}{z_w}\right) \qquad 4.4.1\text{-n}$$

where $\left(\frac{\pi}{2}\,\frac{z}{z_w}\right)$ is expressed in radians.

Step 6. Determine the dynamic-pressure ratio in the plane of symmetry at an arbitrary distance x aft of the wing-root-chord trailing edge by

$$\frac{q}{q_\infty} = 1 - \frac{\Delta q}{q} \qquad 4.4.1\text{-o}$$

Note, that if the distance from the vortex sheet to the point of interest is equal to or greater than the wing wake half-width, the dynamic-pressure ratio at the point of interest is unity, i.e., $q/q_\infty = 1.0$ for $z/z_w \geq 1.0$.



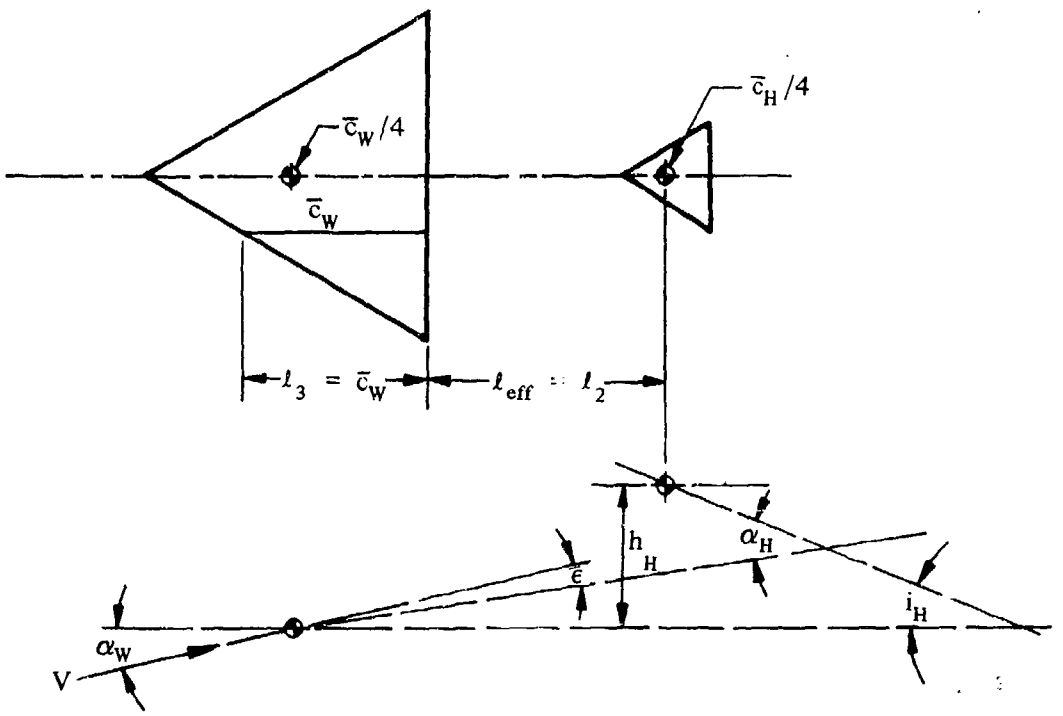
SKETCH (d)

A comparison of test data with dynamic-pressure ratios calculated by this method is given in Table 4.4.1-E.

Sample Problems

1. Subsonic Downwash (Method 1)

Given: The wing-body-tail configuration of Reference 20.



Wing Characteristics:

$A = 2.31 \quad \lambda = 0$

$\Lambda_{c/4} = 52.4^o \quad i_W = 0$

$\Gamma = 0 \quad b = 36.5$ in.

$\bar{c} = 21.1$ in.

NACA $65_{(06)}$–006.5 (free-stream direction)

Horizontal-Tail Characteristics:

$b_H = 11.53$ in. $\qquad h_H = 15.88$ in.

Additional Characteristics:

$\ell_3 = \bar{c}_w$ (delta wing) $\quad \ell_2 = 26.28$ in. $\quad \ell_{eff} = \ell_2$ (delta wing)

Low speed (M = 0.17)

$(\alpha_0)_w = 0 \qquad \left(\alpha_{C_{L_{max}}}\right)_w = 33^o$

α	4^o	8^o	12^o	16^o	20^o	24^o	28^o
C_L	0.15	0.315	0.48	0.655	0.825	0.975	1.115

(wing-alone test data from Reference 20)

Compute:

The final calculations are presented in table form on Page 4.4.1-15. Many of the quantities listed below appear as columns in the table.

Determine the effective wing aspect ratio and the effective wing span.

$$\frac{\alpha - \alpha_0}{\alpha_{C_{L_{max}}} - \alpha_0} = \frac{\alpha - 0}{33.0 - 0} = \frac{\alpha}{33.0}$$

$\frac{A_{eff}}{A}$, $\frac{b_{eff}}{b}$ (Figure 4.4.1-66)

Determine the downwash gradient in the plane of symmetry at the height of the vortex core.

$$\frac{2\ell_2}{b} = \frac{2(26.28)}{36.5} = 1.44$$

$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_v$ (Figure 4.4.1-67)

Determine the vertical position of the vortex core.

$\Delta y = 1.28\%\ c$ (Figure 2.2.1-8)

Leading-edge separation is predominant (Figure 4.4.1-68a); therefore

$$a = h_H - (\ell_2 + \ell_3)\left(\alpha - \frac{0.41\,C_L}{\pi\,A_{eff}}\right) - \frac{b_{eff}}{2}\tan\Gamma \quad \text{(Equation 4.4.1-d)}$$

$$= 15.88 - (26.28 + 21.10)\left(\alpha - \frac{0.41\,C_L}{\pi\,A_{eff}}\right) - 0$$

$$= 15.88 - 47.38\left(\alpha - \frac{0.41\,C_L}{\pi\,A_{eff}}\right)$$

Determine the span of the vortices at the longitudinal location of the quarter-chord point of the tail MAC.

$$b_{v_{ru}} = [0.78 + 0.10\,(\lambda - 0.4) + 0.003\,\Lambda_{c/4}]\;b_{eff} \quad \text{(Equation 4.4.1-f)}$$

$$= [0.78 + 0.10\,(0 - 0.4) + 0.003\,(52.4)]\;b_{eff}$$

$$= 0.897\,b_{eff}$$

$$\xi_{ru} = \frac{0.56\,A}{C_L} = \frac{(0.56)\,(2.31)}{C_L} = \frac{1.294}{C_L}$$

$$b_v = b_{eff} - (b_{eff} - b_{v_{ru}})\left(\frac{2\ell_{eff}}{b\,\xi_{ru}}\right)^{1/2} \quad \text{(Equation 4.4.1-e)}$$

$$= b_{eff} - (b_{eff} - b_{v_{ru}})\left(\frac{1.44}{\xi_{ru}}\right)^{1/2}$$

Determine the average downwash gradient acting on the tail.

$$\left(\frac{\partial\bar{\epsilon}}{\partial\alpha}\right)\Big/\left(\frac{\partial\epsilon}{\partial\alpha}\right)_v = f\left(\frac{2a}{b_v}, \frac{b_H}{b_v}\right) \quad \text{(Figure 4.4.1-68b)}$$

Solution:

(1) α (deg)	(2) $\frac{\alpha-\alpha_0}{\alpha_{C_{L_{max}}}-\alpha_0}$ (1)/33.0	(3) $\frac{A_{eff}}{A}$ (Fig. 4.4.1-66)	(4) $\frac{b_{eff}}{b}$ (Fig. 4.4.1-66)	(5) A_{eff} 2.31(3)	(6) b_{eff} (in.) 36.5(4)	(7) $(\partial\epsilon/\partial\alpha)_v$ (Fig. 4.4.1-67)	(8) C_L Test Values

SKETCH (e)

2. Subsonic Downwash (Method 2)

Given: The wing-body-tail configuration of Reference 20. This is the same configuration as Sample Problem 1 above.

Wing Characteristics:

$A = 2.31$ $\lambda = 0$ $\Lambda_{c/4} = 52.4^{o}$ $i_W = 0$ $\Gamma = 0$

$b = 36.5$ in. NACA $65_{(06)}$-006.5 (free-stream direction)

Horizontal-Tail Characteristics:

$h_H = 15.88$ in.

Additional Characteristics:

$\ell_H = 31.57$ in. Low speed (M = 0.17)

Compute:

$$\frac{2h_H}{b} = \frac{2(15.88)}{36.5} = 0.870$$

$$\frac{2\ell_H}{b} = \frac{2(31.57)}{36.5} = 1.73$$

$K_A = 0.240$ (Figure 4.4.1-69a)

$K_\lambda = 1.43$ (Figure 4.4.1-69b)

$K_H = 0.470$ (Figure 4.4.1-70)

Solution:

$$\frac{\partial \bar{\epsilon}}{\partial \alpha} = 4.44 \left[K_A \, K_\lambda \, K_H \, (\cos \Lambda_{c/4})^{1/2} \right]^{1.19} \quad \text{(Equation 4.4.1-h)}$$

$$= 4.44 \left[(0.240)\,(1.43)\,(0.470)\,(\cos 52.4^o)^{1/2} \right]^{1.19}$$

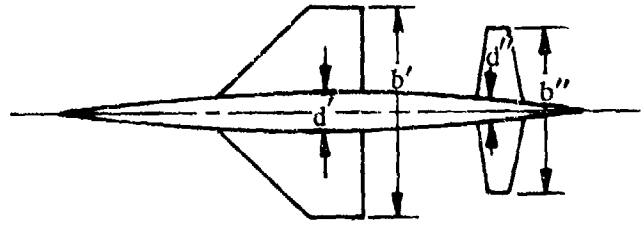
$$= 4.44\,(0.126)^{1.19}$$

$$= 0.377$$

The calculated value compares with a test value of 0.330 from Reference 20.

3. Subsonic Downwash (Method 3)

Given: The same configuration as that of Sample Problem 2 of Paragraph A of Section 4.5.1.1.



Wing Characteristics:

$A_e' = 1.80$ $\lambda_e' = 0.378$ $b'/2 = 141.42$ in. $d'/2 = 26.94$ in.

$\Lambda_{TE} = 0$

Horizontal-Tail Characteristics:

λ_e'' = 0.515 $\quad b''/2$ = 110.64 in. $\quad d''/2$ = 22.08 in.

Additional Characteristics:

Low speed (M = 0.13); β = 0.9915

x = 165.6 in. (distance from the wing trailing edge to the quarter-chord point of the horizontal-tail MAC)

Compute:

Determine the lateral spacing of the trailing vortices at station x.

$\beta A_e'$ = (0.9915) (1.80) = 1.785

$\frac{b_v'/2 - d'/2}{b'/2 - d'/2}$ = 0.785 (Figure 4.4.1-71c)

$b'/2 - d'/2$ = 141.42 – 26.94 = 114.48 in.

$b_v'/2 - d'/2$ = (0.785) (114.48) = 89.87 in.

$b_v'/2$ = 89.87 in. + $d'/2$ = 116.81 in.

$b_v''/2 = b_v'/2$ = 116.81 in. (The method assumes that the lateral spacing of trailing vortices is invariant with longitudinal distance and angle of attack.)

$\frac{b_v''/2}{b''/2} = \frac{116.81}{110.64}$ = 1.056 (This value is used in place of $\frac{y_o}{b_w/2}$ in Figure 4.3.1.3-7.)

Determine the vertical position of the trailing vortices.

$h_v = x \tan\alpha = 165.6 \tan\alpha$ (see table below) (The method assumes the vortex springs from the wing trailing edge and trails in the free-stream direction.)

The ratio $\frac{h_v}{b''/2}$ is used in place of $\frac{z_o}{b_w/2}$ in Figure 4.3.1.3-7.

$\frac{d''/2}{b''/2} = \frac{22.08}{110.64}$ = 0.200 (This value is used in place of $\frac{r}{b_w/2}$ in Figure 4.3.1.3-7.)

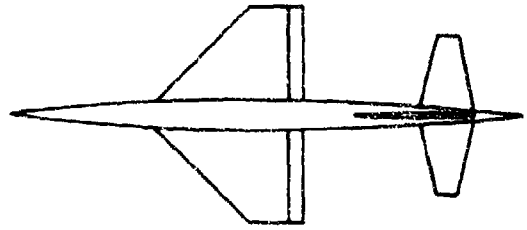
Solution:

α (deg)	h_v / 165.6 tan α (in.)	$\frac{h_v}{b''/2}$	$I_{v_{W''(W'')}}$ Fig. 4.3.1.3-7 @ λ_e'', $\frac{b_v''/2}{b''/2}$ and $\frac{h_v}{b''/2}$
0	0	0	−3.0
5	14.49	0.131	−2.5
10	29.20	0.264	−2.0
15	44.37	0.401	−1.68
20	60.27	0.545	−1.40
23	70.29	0.635	−1.27
26	80.77	0.730	−1.15

The interference factor $I_{v_{W''(W'')}}$ at $\alpha = 0$ is used in Sample Problem 2 of Paragraph A of Section 4.5.1.1 to obtain the effect on total airplane lift, of the wing trailing vortices on the horizontal tail.

4. Subsonic Downwash Due to Flap Deflection

Given: The wing-body-tail configuration of Reference 31



Wing Characteristics:

$A = 2.0$ $b = 23.56$ ft $\Delta C_L = 0.57$ (test data)

Inboard flap station $\eta_i = 0.191$ Outboard flap station $\eta_o = 1.00$

Slotted trailing-edge flaps $\delta_f = 40°$

Tail Characteristic:

$h_H = 0$

Compute:

$$\frac{h_H}{b/2} = \frac{0}{(23.56/2)} = 0$$

$$\frac{b_f}{b/2} = \eta_o - \eta_i$$

$$= 1.00 - 0.191 = 0.809$$

$$\left\{\frac{\Delta\epsilon\, A[b_f/(b/2)]}{\Delta C_L}\right\} = 28.5 \quad \text{(Figure 4.4.1-72)}$$

Solution:

$$\Delta\epsilon = \left\{\frac{\Delta\epsilon\, A[b_f/(b/2)]}{\Delta C_L}\right\} \frac{\Delta C_L}{A[b_f/(b/2)]}$$

$$= (28.5)\,\frac{0.57}{(2.0)\,(0.809)}$$

$$= 10.04^\circ$$

This compares with a test value of 8.8° from Reference 31.

5. Subsonic Dynamic-Pressure Ratio

Given: A wing-tail configuration of Reference 9

Wing Characteristics:

$A = 6.0$ $\lambda = 1.0$ $\bar{c} = 10.0$ in. $S_W = 600$ sq in. $S_{wet} = 1200$ sq in.

NACA 0015 airfoil (x_t @ 0.30c)

Additional Characteristics:

$x = 20.0$ in. (survey station location, aft of wing trailing edge)

Low speed $R_\ell = 0.62 \times 10^6$ (based on $\bar{c}$) $\gamma = 0$

Smooth surface (assume $k = 0$) $S_{ref} = S_W = 600$ sq in.

α	0	1°	2°	3°	4°	6°	8°
C_L	−.01	.055	.115	.175	.240	.360	.485

(test data from Reference 9)

Compute:

Determine the half-width of the wake.

$\ell/k = \infty$; read C_f at given R_ℓ

$C_f = 0.00487$ (Figure 4.1.5.1-26)

$\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] = 1.225$ (figure 4.1.5.1-28a, for L = 1.2)

$\cos \Lambda_{(t/c)_{max}} = \cos 0 = 1.0$

$R_{L.S.} = 1.07$ (Figure 4.1.5.1-28b)

$\frac{S_{wet}}{S_{ref}} = \frac{1200}{600} = 2.0$

$C_{D_0} = C_f \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right] R_{L.S.} \frac{S_{wet}}{S_{ref}}$ (Equation 4.1.5.1-a)

$= (0.00487)(1.225)(1.07)(2.0)$

$= 0.0128$

$x/\bar{c} = 20.0/10.0 = 2.0$

$\frac{z_w}{\bar{c}} = 0.68 \sqrt{C_{D_0}\left(\frac{x}{\bar{c}} + 0.15\right)}$ (Equation 4.4.1-j)

$= 0.68 \sqrt{(0.0128)(2.15)}$

$= 0.113$

Determine the downwash in the plane of symmetry at the vortex sheet.

$\epsilon = \frac{1.62\, C_L}{\pi A}$ (Equation 4.4.1-k)

$= \frac{1.62\, C_L}{\pi\, 6.0} = 0.0859\, C_L$ (radians)

$= 4.92\, C_L$ (degrees) (see calculation table below)

Determine the vertical distance z from the vortex sheet to the point of interest.

$z = x \tan (\gamma + \epsilon - \alpha)$ (Equation 4.4.1-ℓ)

$= 20.0 \tan (0 + \epsilon - \alpha) = 20.0 \tan (\epsilon - \alpha)$ (see calculation table below)

Determine the dynamic-pressure-loss ratio at the wake center.

$$\left(\frac{\Delta q}{q}\right)_o = \frac{2.42\left(C_{D_0}\right)^{1/2}}{\frac{x}{\bar{c}} + 0.30} \qquad \text{(Equation 4.4.1-m)}$$

$$= \frac{2.42(0.0128)^{1/2}}{2.0 + 0.30} = 0.119$$

Determine the dynamic-pressure-loss ratio for points not on the wake center line.

$$\frac{\Delta q}{q} = \left(\frac{\Delta q}{q}\right)_o \cos^2\left(\frac{\pi}{2}\,\frac{z}{z_w}\right) \qquad \text{(Equation 4.4.1-n)}$$

$$= 0.119\ \cos^2\left(\frac{\pi}{2}\,\frac{z}{1.13}\,\frac{57.3}{1}\right)$$

$$= 0.119\ \cos^2\ (79.65\ z) \qquad \text{(see calculation table below)}$$

Solution:

The dynamic-pressure ratio in the plane of symmetry at a distance x = 20.0 in. aft of the wing-root-chord trailing edge is

$$\frac{q}{q_\infty} = 1 - \frac{\Delta q}{q} \qquad \text{(Equation 4.4.1-o)} \qquad \text{(see calculation table below)}$$

* $q/q_\infty = 1.0$ when $z/z_w \geq 1.0$.

The calculated results are compared with test values from Reference 9 in Table 4.4.1-E. (This is the second configuration given in Table 4.4.1-E.)

B. TRANSONIC

Downwash

In general, the downwash gradient is proportional to the lift-curve slope. The transonic lift-curve-slope characteristics are discussed in detail in Section 4.1.3.2. The following discussion summarizes these transonic characteristics.

For thin, low-aspect-ratio wings the downwash gradient varies smoothly with Mach number. The typical variation is similar to the lift-curve-slope variation for Type "B" wings shown on Page 4.1.3.2-13. For thick, high-aspect-ratio wings at low angles of attack the variation is like that of Type "A" wings (shown on the same page), but at high angles of attack the downwash-gradient variation of these wings is smooth.

The erratic behavior of the thicker wings at low angles of attack is frequently accentuated by shock-induced boundary-layer separation, which can cause significant changes in the span-load characteristics and hence in the downwash distribution behind a wing.

No design charts for the transonic range are presented, because so few flow surveys are available.

Dynamic-Pressure Ratio

No method has been suggested in the literature for estimating the dynamic-pressure ratio at transonic speeds. Furthermore, few data measuring this parameter are known to exist. The method suggested herein is therefore tentative.

DATCOM METHODS

Transonic Downwash

No accurate method is available for the prediction of transonic downwash characteristics. It is suggested that values be approximated by assuming that the downwash gradient is proportional to the lift-curve slope as given in Section 4.1.3.2 for low angles of attack and in Section 4.1.3.3 for high angles of attack.

Transonic Dynamic-Pressure Ratio

For estimating the transonic dynamic-pressure ratio, it is suggested that the method presented in Paragraph A above be applied, with the appropriate zero-lift drag values from Section 4.1.5.1 (excluding wave drag).

C. SUPERSONIC

Downwash

At supersonic speeds downwash is caused by two factors. First, the region behind the trailing-edge shock or expansion wave is distorted by the wing vortex system in a manner similar to that which occurs at subsonic speeds. Because of the variation in span load, a vortex sheet is shed that rolls up with increasing downstream distance from the surface. Tip vortices similar to their subsonic counterparts are also present. At the supersonic Mach numbers, however, the entire flow field is swept back and isolated regions of

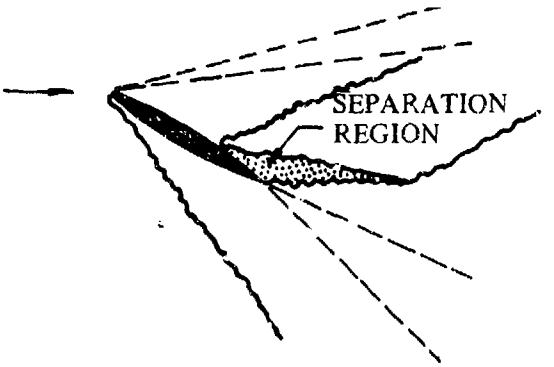
influence may exist over certain portions of the wing surface and in the flow field behind it. For instance, regions not affected by the wing tip are generally present. For a rectangular wing such a region can be treated in a two-dimensional manner, i.e., no lateral variation of downwash exists.

Secondly, a change in flow direction occurs in the flow region between the leading- and trailing-edge shock or expansion waves. Since this region of the flow field does not "see" the wing vortex system, numerical values of downwash can be calculated by applying shock-expansion theory. In order to simplify the calculations, it is standard practice to perform the calculations with wing-root geometry and to assume two-dimensional flow. For cases in which the vehicle component (i.e., horizontal tail) immersed in the wing flow field has less span than the wing, this latter assumption is justified. For cases in which the aft component is large compared to the forward component (i.e., a wing following a canard surface), this assumption is not justified, because of the significant spanwise downwash variations associated with the wing tips. Behind the trailing-edge shock or expansion wave the downwash due to these compressibility effects is zero.

Dynamic-Pressure Ratio

Variations in the dynamic-pressure ratio exist throughout the field of influence of a wing in supersonic flight. A thin viscous wake exists behind the wing, with characteristics quite similar to its subsonic counterpart (see Paragraph A above). In addition, the nonviscous flow region behind the leading-edge shock or expansion wave also exhibits dynamic-pressure-ratio variations due to compressibility effects. The application of shock-expansion theory has been shown to yield a reasonable approximation for the dynamic-pressure ratio in the nonviscous portion of the flow field.

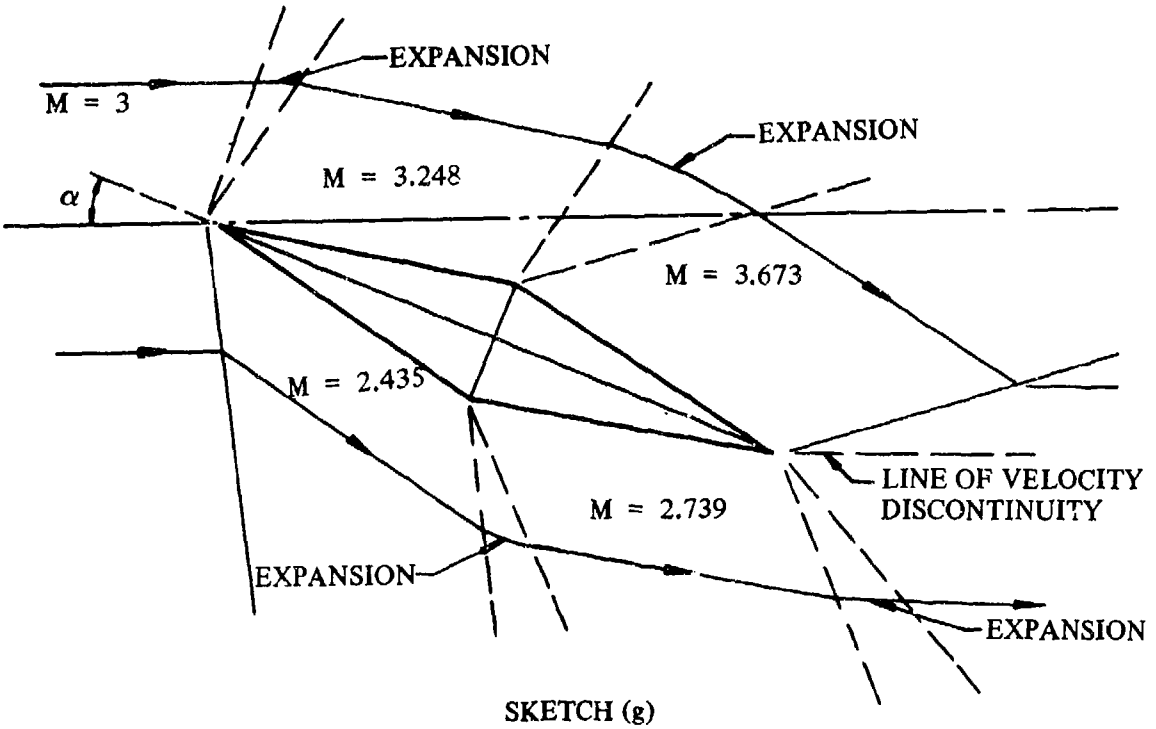
The existence of the trailing-edge shock wave on the upper surface can cause a significant boundary-layer-separation region under conditions of low Reynolds number and/or large angles of attack (see Sketch (f)). This region of separation creates a wide wake near the trailing edge that is not predicted by the method presented herein.



SKETCH (f)

Mach Number Effects

The local Mach number between the leading- and trailing-edge shock or expansion waves can vary significantly from the free-stream value. Expansion fields increase the Mach number, and compression fields decrease the Mach number. Vehicle components immersed in these flow fields exhibit different aerodynamic characteristics because of the varying Mach number. This is illustrated in Sketch (g) for a double wedge airfoil.



SKETCH (g)

Lumped Parameter

At least one author(Reference10) has treated the flow field at supersonic speeds by combining the effects of downwash, dynamic-pressure ratio, and Mach number into a single lumped parameter. This approach gives valid values for determining the effect of the wing shock-expansion field on stabilizer effectiveness but cannot give the isolated effects. In the Datcom, this analysis is presented in Section 4.5.1.2.

DATCOM METHODS

Supersonic Downwash

Method 1

The downwash behind a straight-tapered wing for either subsonic or supersonic leading and trailing edges can be approximated by the theoretical method presented in Reference 11. The basic theory uses a system of 20 swept unit horseshoe vortices placed along the load line of the wing (assumed to be the midchord line in the Datcom). The vortices are then weighted by the span-load variation. The integrated contribution of each bound and each trailing vortex is then determined as a function of the spatial coordinates and presented in either table or chart form.

For computing downwash in the plane of symmetry, tables have been prepared based on the downwash due to the system of swept unit horseshoe vortices.

For computing the spanwise variation of downwash, design charts have been prepared based on an approximation of the downwash due to the system of swept unit horseshoe vortices. The swept lifting line

has been approximated with semi-infinite unswept horseshoe vortices. Although this approximation does not predict the exact magnitude of the spanwise variation in downwash, it has been applied in an effort to simplify the final solution and to allow design charts to be presented in lieu of lengthy calculation tables. By using this approach, the calculated level of the spanwise downwash variation is adjusted, if necessary, to the value at the plane of symmetry obtained using the tables.

This method is presented in the Datcom because of its wide range of applicability, even though the tables and design charts of Reference 11 have not been reproduced. However, the basic equations are presented for use in the event that the reference is not available to the user. The span loading of the particular wing being considered must be known. At the present time this information must be obtained from sources other than the Datcom, for instance Reference 12.

The derivative $\frac{\partial \epsilon}{\partial \alpha}$ at a particular point (x, y, z) in the flow field not close to the trailing edge of the wing is obtained by means of the equation

$$\frac{\partial \epsilon}{\partial \alpha} = -\frac{w}{V_\infty \alpha} \qquad 4.4.1\text{-p}$$

For points on the plane of symmetry

$$-w = 2\sum_{i=o}^{n_2} \frac{\Gamma_{y_{i+1}} - \Gamma_{y_{i-1}}}{b/2} F_w(|y_{i,o}|) + \frac{\Gamma_o}{b/2} F_{w,o} \qquad 4.4.1\text{-q}$$

For points not on the plane of symmetry (spanwise downwash)

$$-w = -\sum_{i=n_1}^{o} \frac{\Gamma_{y_{i+1}} - \Gamma_{y_{i-1}}}{b/2} F_w(Y_{i,o}) + \sum_{i=o}^{i=n_2} \frac{\Gamma_{y_{i+1}} - \Gamma_{y_{i-1}}}{b/2} F_w(Y_{i,o}) \qquad 4.4.1\text{-r}$$

The functions $F_w(|y_{i,o}|)$, $F_w(Y_{i,o})$, and $F_{w,o}$ are presented in Reference 11 as Table II, Figure 6, and Table III, respectively, and are expressed mathematically by

$$F_w(|y_{i,o}|) = \frac{-|y_{i,o}|X_{i,o}^3 + X_{i,o}(z_o^2 - y_{i,o}^2) + \beta m^2 |y_{i,o}|X_{i,o}(|y_{i,o}|^2 + 2z_o^2) + \beta m^2 |y_{i,o}|(z_o^2 + |y_{i,o}|^2)}{4\pi\sqrt{X_{i,o}^2 - \beta^2 m^2 (|y_{i,o}|^2 + z_o^2)}\,[(|y_{i,o}|X_{i,o} + z_o^2 + |y_{i,o}|^2)^2 + z_o^2(X_{i,o}^2 - \beta^2 m^2 |y_{i,o}|^2 - \beta^2 m^2 z_o^2)]} \qquad 4.4.1\text{-s}$$

$$F_w(Y_{i,o}) = \frac{Y_{i,o}\bar{X}_i^3 - Y_{i,o}\bar{X}_i(Y_{i,o}^2 + 2z_o^2)}{4\pi\sqrt{\bar{X}_i^2 - Y_{i,o}^2 - z_o^2}\,(\bar{X}_i^2 - z_o^2)(Y_{i,o}^2 + z_o^2)} \qquad 4.4.1\text{-t}$$

$$F_{w,o} = \frac{x_o}{\pi\sqrt{x_o^2 - \beta^2 m^2 z_o^2}\,[x_o^2 + z_o^2(1 - \beta^2 m^2)]} \qquad 4.4.1\text{-u}$$

Definitions applying to this method are given as follows (symbolism used for this method is identical with that of Reference 11).

V_∞ = free-stream velocity.

α = angle of attack in radians.

x,y,z = standard rectangular Cartesian coordinates with the origin at the 50-percent-chord point of the root section.

x_i, y_i = standard rectangular Cartesian coordinates of the inboard corners of the horseshoe vortices.

$$x_o = \frac{mx}{b/2}$$

$$x_{i,o} = \pm \frac{mx_i}{b/2} = \pm y_{i,o}$$

$$X_{i,o} = x_o - x_{i,o} = x_o \pm y_{i,o} = \frac{mX_i}{b/2}$$

$$\bar{X}_i = \bar{x} \pm \frac{y_{i,o}}{\beta m}$$

$$\bar{x} = \frac{x}{\beta b/2} \left(= \frac{x_o}{\beta m} \text{ for swept lifting line} \right)$$

$$y_o = \frac{y}{b/2}$$

$$y_{i,o} = \frac{y_i}{b/2}$$

$$Y_{i,o} = y_o - y_{i,o} = \frac{Y_i}{b/2}$$

$$z_o = \frac{z}{b/2}$$

i = variable index used in summation, designating a particular horseshoe vortex. Values of i from o to n_1 are associated with negative values of y_i and values from o to n_2 with positive values of y_i.

m = slope of lifting line ($\cot|\Lambda_{c/2}|$)

n_1, n_2 = value of i at left- and right-hand wing tips of a swept wing, looking from trailing edge to leading edge.

Γ_y = value of circulation at any spanwise station. If the load distribution is given in terms of the section lift coefficient, the circulation is determined by the equation

$$\Gamma_y = 1/2\, c_\ell Vc$$

where c is the local chord.

Γ_o = circulation at $y_i = 0$

The suggested method of adjusting the calculated spanwise downwash given by Equation 4.4.1-r is to translate the curve of calculated spanwise downwash so that the value at the plane of symmetry ($y_o = 0$) is made to coincide with that computed by using Equation 4.4.1-q. This approach is illustrated in the sample problem on Page 4.4.1-35.

For locations near the wing trailing edge, lifting-line theory does not give adequate answers and a more precise determination must be made. An exact equation is given in Reference 13 for determining this value, which involves the local angle of attack and the perturbation velocity at the trailing edge.

The effects of vortex-sheet displacement and distortion have not been included in this method, although this effect may be approximated by the theory of Reference 14. (See Steps 1 and 2 of Method 2 that follows.) The displacement of the vortex sheet at the center line is determined, and it is assumed that this displacement is constant for all lateral stations. Therefore, the effects of vortex-sheet displacement and distortion are approximated by calculating a new z_o value to be used in this method. In using the design charts associated with Method 2, it should be noted that the origin of the spatial coordinates is located at the wing apex rather than at the 50-percent-chord point of the root section as for this method.

Method 2

Supersonic downwash for straight-tapered wings with supersonic leading edges ($\beta \cot \Lambda_{LE} > 1$) and supersonic trailing edges ($\beta \cot \Lambda_{TE} > 1$) may be computed by means of the charts presented in Reference 14. (It should be noted that Figures 4.4.1-76a and -76d from Reference 14 have been expanded somewhat, based on available test data. In addition, Figure 4.4.1-76e has been obtained semiempirically by using Figure 4.4.1-76d as a basis and should be applied with caution.) The charts, based on lifting-line theory, are derived for flat-plate wings and include a correction for the displacement and distortion of the trailing vortex sheet. The lifting line is assumed to be at $\Lambda_{c/2}$ for the rectangular and trapezoidal wings and at $\Lambda_{3c/4}$ for the triangular wings. Near the sonic-leading-edge condition, the lift of a finite-thickness wing is significantly less than the values for flat-plate wings (see Section 4.1.3.2). The downwash gradient $\partial\bar{\epsilon}/\partial\alpha$ may be corrected to account for wing thickness effects as indicated in the procedure below. Table 4.4.1-F presents a data summary and substantiation. The limited number of test points presented precludes substantiation of this method over other than very limited ranges of planform and flow parameters.

The derivative $\dfrac{\partial\bar{\epsilon}}{\partial\alpha}$ for wings with supersonic leading and trailing edges is obtained by the following procedure:

Step 1. For the Mach number under consideration, the coordinates of the point where the downwash is desired are reduced to the parameters $\frac{2x}{\beta b}$, $\frac{2y}{b}$, and $\frac{2z}{b}$ measured from an origin at the apex of the wing (x, y, and z are positive in the conventional sense and refer to wind axes).

Step 2. The effects of displacement and distortion of the vortex sheet are accounted for by determining the displacement of the sheet at the center line and assuming that this displacement is constant for all lateral stations (see Reference 14). The vertical displacement 2h/b of the vortex sheet at the center line is obtained from Figure 4.4.1-74 (derived from Reference 8). This value is added to the parameter $\frac{2z}{b}$ from Step 1 to obtain the effective value of the height parameter relative to the displaced vortex. This effective parameter is designated $\left(\frac{2z}{b}\right)_{eff}$

Step 3. For the values of $\frac{2x}{\beta b}$, $\frac{2y}{b}$, and $\left(\frac{2z}{b}\right)_{eff}$, the derivative $\frac{\partial \bar{\epsilon}}{\partial \alpha}$ is obtained from Figures 4.4.1-76a through 4.4.1-76e, depending upon the appropriate wing planform geometry. This value is valid for finite-thickness wings except near the sonic-leading-edge condition, where an additional correction is required.

Step 4. For near-sonic-leading-edge conditions, the value of $\frac{\partial \bar{\epsilon}}{\partial \alpha}$ obtained from Step 3 is multiplied by the thickness correction factor from Figure 4.1.3.2-60.

Step 5. For moderate angles of attack below wing stall, where the nonlinear lift becomes important, the downwash gradient determined from Step 3 can be approximately corrected by the equation

$$\frac{\partial \bar{\epsilon}}{\partial \alpha} = \frac{(C_{N_\alpha})_{4.1.3.3}}{(C_{N_\alpha})_{4.1.3.2}} \left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)_{step\ 3} \qquad 4.4.1\text{-v}$$

where

$(C_{N_\alpha})_{4.1.3.3}$ is the local normal-force-curve slope from Paragraph C of Section 4.1.3.3 for the angle of attack under consideration. It is $(C_{N_\alpha})_{4.1.3.2}$ corrected for thickness effects.

$(C_{N_\alpha})_{4.1.3.2}$ is the normal-force-curve slope at zero angle of attack from the straight-tapered-wing method of Paragraph C of Section 4.1.3.2, excluding the thickness correction factor of Figure 4.1.3.2-60.

$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_{step\ 3}$ is the downwash gradient from Step 3.

Step 6. The average downwash over the span of a horizontal tail is obtained by computing the downwash at several spanwise locations and computing an average value.

Step 5 should be used with caution. Nonlinear lift (which is characteristic of low-aspect-ratio configurations) is caused by strong vortices that generally move inboard with increasing angle of attack and may have a spanwise spacing comparable to that of the downstream surfaces.

For those configurations that do not satisfy the supersonic leading- and trailing-edge condition, an approximation (used in Digital Datcom) for the downwash gradient may be obtained by using Equation 4.4.1-k, i.e.,

$$\epsilon = \frac{1.62\, C_L}{\pi A} \quad \text{(radians)}$$

From this equation a relationship is obtained for ϵ as a function of angle of attack. Plotting the curve from this relationship enables the user to obtain a value for $\partial\epsilon/\partial\alpha$ at a specific angle of attack. However, this approximation should be used with caution since it has not been substantiated in the supersonic speed regime.

Method 3

For low-aspect-ratio or canard configurations the vortex pair from the forward surface interacts more directly with the aft surface and the following method from Reference3 is applicable.

Step 1. The spatial position of the trailing vortices is first determined relative to the aft surface. The lateral spacing is determined from Figure 4.4.1-80 as a function of the exposed forward-surface planform geometry. This spacing is invariant with longitudinal distance and angle of attack. The vertical position is determined by assuming that the vortex springs from the trailing edge at the previously determined lateral position and trails in the free-stream direction. The pertinent vertical dimension is the distance between the quarter-chord point of the MAC of the aft surface and the vortex as determined above.

Step 2. The vortex interference factor $I_{v\bar{W}'(W'')}$ is obtained from Figures 4.3.1.3-7a through 4.3.1.3-7ℓ as a function of the lateral and vertical vortex positions, determined in Step 1, and the geometry of the aft panel. (The primed notation refers to the forward panel and the double-primed notation refers to the aft panel.)

Step 3. The vortex interference factor so determined is used in Sections 4.5.1.1 and 4.5.1.2 to obtain the lift generated on the aft surface for complete wing-body-tail combinations.

This method is similar to Method 3 for estimating subsonic downwash in paragraph A. The use of the subsonic sample problem on Page 4.4.1-17 as a guide is essential in applying this method.

Supersonic Dynamic-Pressure Ratio

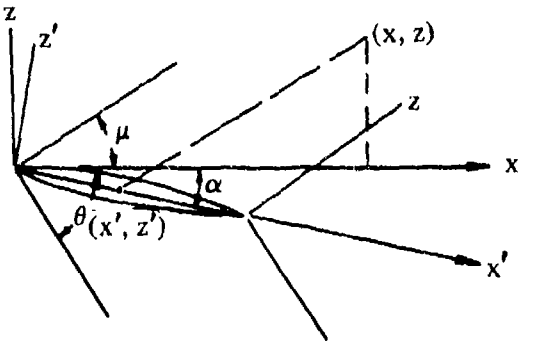
The dynamic-pressure ratio at supersonic speeds is estimated separately for the nonviscous and viscous flow regions. The nonviscous flow region is approximated by the flow emanating from the wing in the absence of separation, and bound by shock or expansion waves. The viscous flow region is considered to be the viscous wake behind a wing, with attached flow in the vicinity of the trailing edge.

Nonviscous Flow Field

The dynamic-pressure ratio in the nonviscous flow field of a wing is estimated by means of shock-expansion theory. Application of this technique assumes that the flow field is two-dimensional. For a rectangular wing, the region outside the influence of the tips is two-dimensional. Therefore, the method applied to rectangular wings will, in general, predict the experimental trends and even the magnitude of the flow-field quantities with fair accuracy, except in the region influenced by the tip or in the viscous wake. For some rectangular wings of high effective aspect ratio (βA), the greater portion of the flow field can be predicted reasonably well by shock-expansion theory.

Strictly speaking, this method can not be applied to sweptback wings, since the large portion of the flow field of such wings will not be two-dimensional. However, the method might furnish a good approximation to the dynamic-pressure-ratio variations, because the theory does account for the presence of shock and expansion waves. In Reference 15 the method has been applied to a triangular wing with supersonic leading edges, and the dynamic-pressure ratio was predicted fairly accurately except in the viscous flow region. No comparison of calculated results with experimental data has been made for wings with subsonic leading edges.

The theory as applied herein allows calculation of the dynamic-pressure ratio on an arbitrarily selected survey plane located downstream from the wing. The geometric relationship between points on this plane and points on the airfoil from which the disturbance originates is illustrated in Sketch (h). It is assumed that disturbances emanating from a point on the wing (x '– z 'plane)



SKETCH (h)

proceed downstream at the theoretical Mach angle μ for surfaces with an initial expansion angle, and at the shock angle θ for surfaces with an initial compression angle. It is further assumed that the dynamic-pressure ratio at some point (x, y) on the survey plane is the same as that at the corresponding point (x', y') on the airfoil surface.

The basic approach is as follows:

1. For a given airfoil and flow condition determine the points (x, y) in the flow field at the survey plane corresponding to the points (x', y') on the airfoil from which the disturbance is assumed to originate.

2. By using shock-expansion theory, determine the dynamic-pressure ratio at point (x, y) in the flow field – which is assumed to be the same as that at corresponding point (x', y').

In applying shock-expansion theory the flows on the upper and lower airfoil surfaces can be treated separately. The type of flow (either expansion or compression) at a given point is governed by the sign of the flow-deflection angle at that point.

If the flow-deflection angle is positive, the flow expands isentropically and the characteristics of the flow are given by Prandtl-Meyer expansion relations. If the flow quantities are known at one point, the values at any second point can be calculated by identifying the change in the flow angle between the two points.

If the flow-deflection angle is negative, the flow is compressed and the flow characteristics are given by oblique-shock-wave relations. The Datcom presents a design chart showing the variation of shock angle with flow-deflection angle for various upstream Mach numbers. In addition, since flow through weak shock waves is nearly isentropic, compressions through small angles may also be calculated by regarding them as reversed Prandtl-Meyer expansions.

Although expansion and compression waves proceed at different angles and therefore interact, this simplified method does in some cases give a good approximation of the dynamic-pressure ratio. The accuracy of the method deteriorates as the wing thickness and/or distance of the survey plane aft of the wing increase.

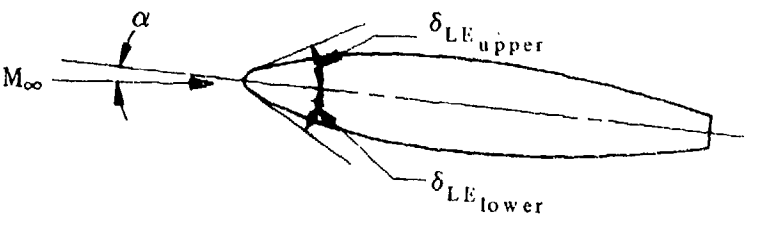
The following steps outline the procedure to be followed for determining the supersonic dynamic-pressure ratio in the nonviscous flow field. The use of the sample problem on Page 4.4.1-41 as a guide is essential in applying this procedure.

Step 1. For a given airfoil and flow condition, determine the flow-deflection angles on the upper and lower airfoil surfaces at the leading edge.

For an airfoil at a positive angle of attack the flow-deflection angle at the leading edge is given by:

For the upper airfoil surface

$$\delta'_{LE} = \alpha - \delta_{LE_{upper}}$$



For the lower airfoil surface

$$\delta'_{LE} = -\alpha - \delta_{LE_{lower}}$$

where the δ' values are the flow-deflection angles and the δ values are the slopes of the airfoil surface with respect to the chord plane x'.

If δ'_{LE} is positive the surface has an initial expansion angle. If δ'_{LE} is negative the surface has an initial compression angle.

Step 2. Determine the points (x , z) in the flow field corresponding to the points (x' , z') on the airfoil from which the disturbance is assumed to have originated.

For surfaces with an initial expansion angle

$$z = \frac{-x' + x\cos\alpha - \dfrac{x\sin\alpha}{\tan(\mu+\alpha)}}{\sin\alpha + \dfrac{\cos\alpha}{\tan(\mu+\alpha)}} \qquad \text{4.4.1-w}$$

where

x' is an arbitrarily chosen point on the airfoil chord plane, positive aft of the leading edge.

x is the location of the arbitrarily chosen survey plane on the x-axis, positive aft of the leading edge.

α is the angle of attack in degrees.

μ is the Mach angle, $\mu = \sin^{-1}\dfrac{1}{M_\infty}$.

For surfaces with initial compression angles

$$z = \frac{-x' + x\cos\alpha - \dfrac{x\sin\alpha}{\tan(\alpha-\theta)}}{\sin\alpha + \dfrac{\cos\alpha}{\tan(\alpha-\theta)}} \qquad \text{4.4.1-x}$$

where x', x, and α are defined above and θ is the shock-wave angle obtained as a function of the free-stream Mach number and the flow-deflection angle from Figure 4.4.1-81.

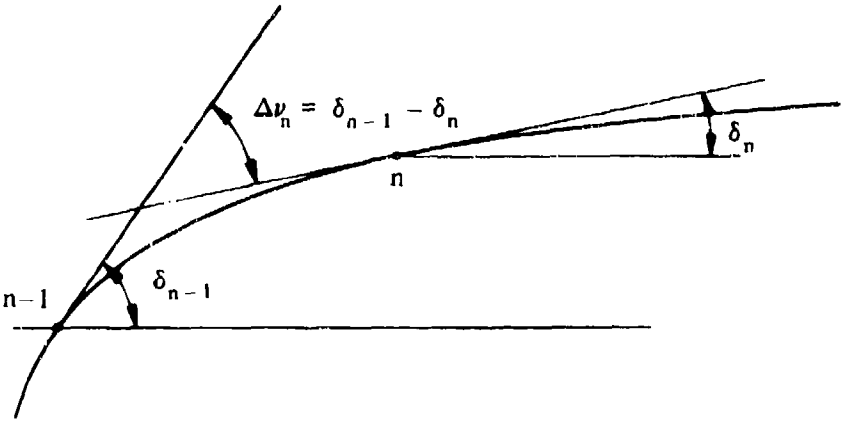
Equations 4.4.1-w and 4.4.1-x are based on the assumption that the disturbance originates from a point located on the airfoil chord. Therefore, $z' = 0$.

Step 3. Determine the dynamic-pressure ratio at point (x , z) – which is assumed to be the same as that at corresponding point (x', z').

For expansion fields (positive flow-deflection angles) the procedure is as follows:

a. Using the Mach number upstream of a point M_{n-1}, enter Figure 4.4.1-82 and obtain ν_{n-1}, the Prandtl-Meyer angle (angle through which the supersonic stream is turned to expand from M = 1 to M > 1). n refers to an individual point.

b. Determine $\Delta\nu_n$, the change in flow-deflection angle between two points. In expanding from the free stream to a point downstream of the leading edge, $\Delta\nu_n = \alpha - \delta_{LE}$. On the airfoil surface $\Delta\nu_n$ is simply the change in surface slope between two points; i.e., $\Delta\nu_n = \delta_{n-1} - \delta_n$.



c. Determine the new Prandtl-Meyer angle at point n by $\nu_n = \nu_{n-1} + \Delta\nu_n$

d. Enter Figure 4.4.1-82 with ν_n and read M_n.

e. Using M_{n-1} (upstream Mach number) and M_n (Mach number at point in question), enter Figure 4.4.1-82 and read the ratio of dynamic pressure to total pressure q/p_t at the respective Mach numbers. Then

$$\frac{q_n}{q_\infty} = \frac{(q/p_t)_n}{(q/p_t)_{n-1}} \frac{q_{n-1}}{q_\infty} \qquad 4.4.1\text{-y}$$

For compression fields (negative flow-deflection angles) the procedure is as follows:

The dynamic-pressure ratio following an oblique shock is given by

$$\frac{q_n}{q_{n-1}} = \frac{60}{M_{n-1}^2} \frac{(1 + 0.2\, M_{n-1}^2)^{7/2}}{(5 + M_{n-1}^2 \sin^2\theta)^{5/2}} \qquad 4.4.1\text{-z}$$

where n refers to an individual point and

M_{n-1} is the Mach number upstream of the shock.

θ is the shock-wave angle obtained as a function of the upstream Mach number M_{n-1} and the flow-deflection angle δ' at the point in question.

The Mach number behind an oblique shock is given by

$$M_n = \left[\frac{M_{n-1}^2 \sin^2\theta + 5}{7\, M_{n-1}^2 \sin^2\theta - 1}\right]^{1/2} \frac{1}{\sin(\theta + \delta')} \qquad 4.4.1\text{-aa}$$

where M_{n-1}, θ, and δ are defined under Equation 4.4.1-z.

At the airfoil trailing edge the flow over both the upper and lower surfaces of the airfoil returns to nearly free-stream flow. If the Mach number at the trailing edge is greater than the free-stream Mach number, the flow is compressed through a shock wave θ_{TE} corresponding to the Mach number at the trailing edge, and the flow-deflection angle $\delta' = -\alpha + \delta_{TE}$. If the Mach number at the trailing edge is less than the free-stream Mach number, the flow is expanded through the angle $\Delta\nu_{TE} = \alpha + \delta_{TE}$.

This procedure is best applied by starting with the leading edge. The sample problem on Page 4.4.1-41 illustrates the procedure.

Viscous Flow Field

No known method exists in the literature for estimating the dynamic-pressure ratio in the viscous wake of a wing at supersonic speeds. Because of the similarity of this part of the flow field to the corresponding viscous wake at subsonic speeds, it is recommended that the method presented for determining the subsonic dynamic-pressure ratio in Paragraph A be applied at supersonic Mach numbers. In using this method the appropriate value of C_{D_0} must be obtained from Paragraph C of Section 4.1.5.1.

It should be noted that the x- and z-distances used in this method are measured from different origins from those used in the method for the nonviscous flow field. In this method x is measured from the wing-root trailing edge and z is measured from the wake center line.

Mach Number Effects

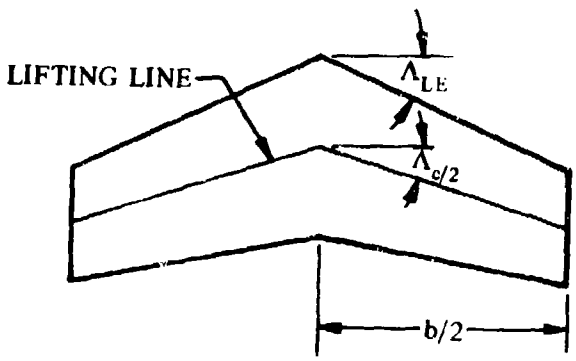
No explicit method is presented in the Datcom for determining the Mach number field about an airfoil. However Reference 16 explains and illustrates a calculation process. Compressibility tables such as those of Reference 17 can be of great help in estimating compressible-flow properties

Sample Problems

1. Supersonic Downwash (Method 1)

Given:

The sample problem presented in Reference 11. The calculation procedure is illustrated by showing calculations for one Mach number and two points in the flow field, one in the plane of symmetry ($y_o = 0$) and one outside the plane of symmetry at $y_o = 0.15$. The points for which the downwash calculations are given are both located at longitudinal position $x_o = 2.2$ and vertical position $z_o = 0$.



A = 3.57 $\quad\quad$ λ = 0.565

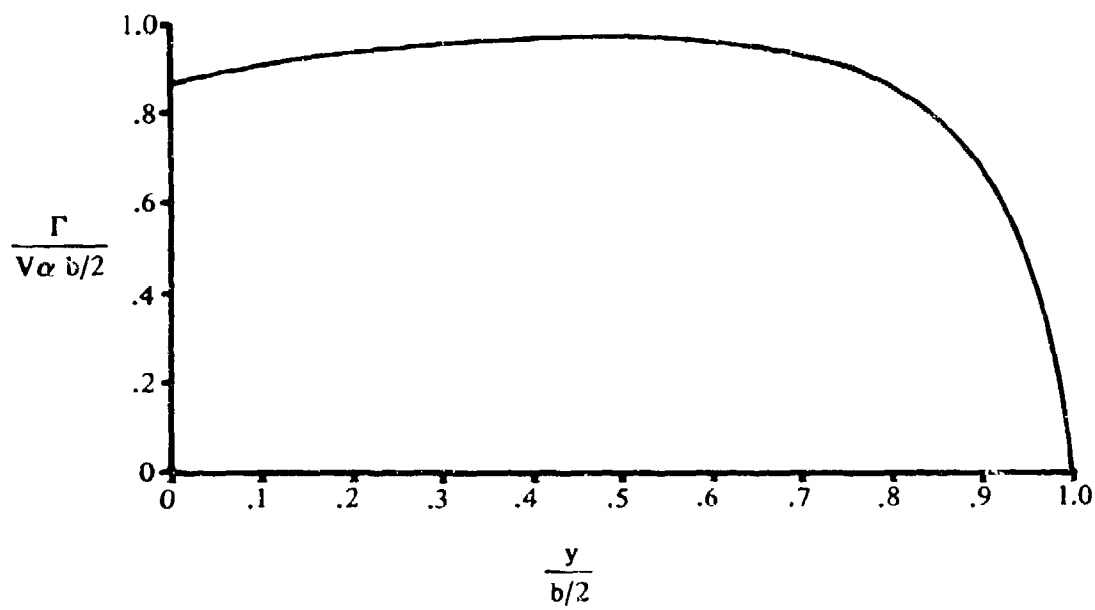
Λ_{LE} = 38.8° $\quad\quad$ $\Lambda_{c/2} = \Lambda_{\text{lifting line}}$ = 33°

m_o = cot Λ_{LE} = 1.244

m = cot $\Lambda_{c/2}$ = 1.54

M = 1.64; β = 1.30

The following span-load distribution from Reference 12 at a constant angle of attack as f(A, λ, M, Λ_{LE}).



Compute: Plane of Symmetry

Determine the downwash gradient in the plane of symmetry (y_o = 0) at z_o = 0, x_o = 2.2.

$$-w = 2\sum_{i=o}^{n_2} \frac{\Gamma_{y_{i+1}} - \Gamma_{y_{i-1}}}{b/2} F_w\ (|y_{i,o}|) + \frac{\Gamma_o}{b/2} F_{w,o}$$

(Equation 4.4.1-q)

(see calculation table below)

Solution: Plane of Symmetry

$$\frac{\partial \epsilon}{\partial \alpha} = -\frac{w}{V_\infty \alpha} \quad \text{(Equation 4.4.1-p)}$$

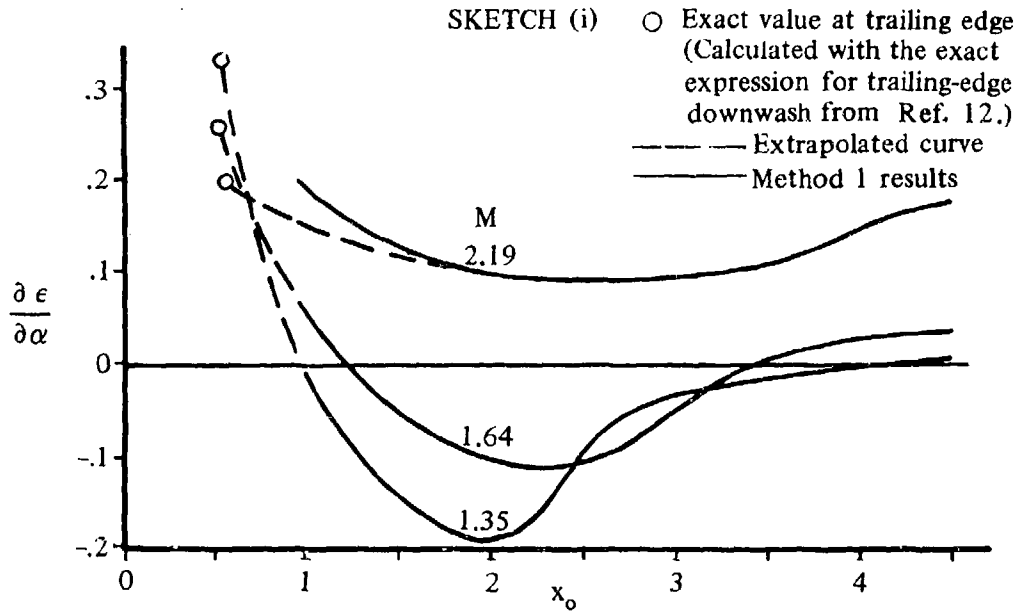
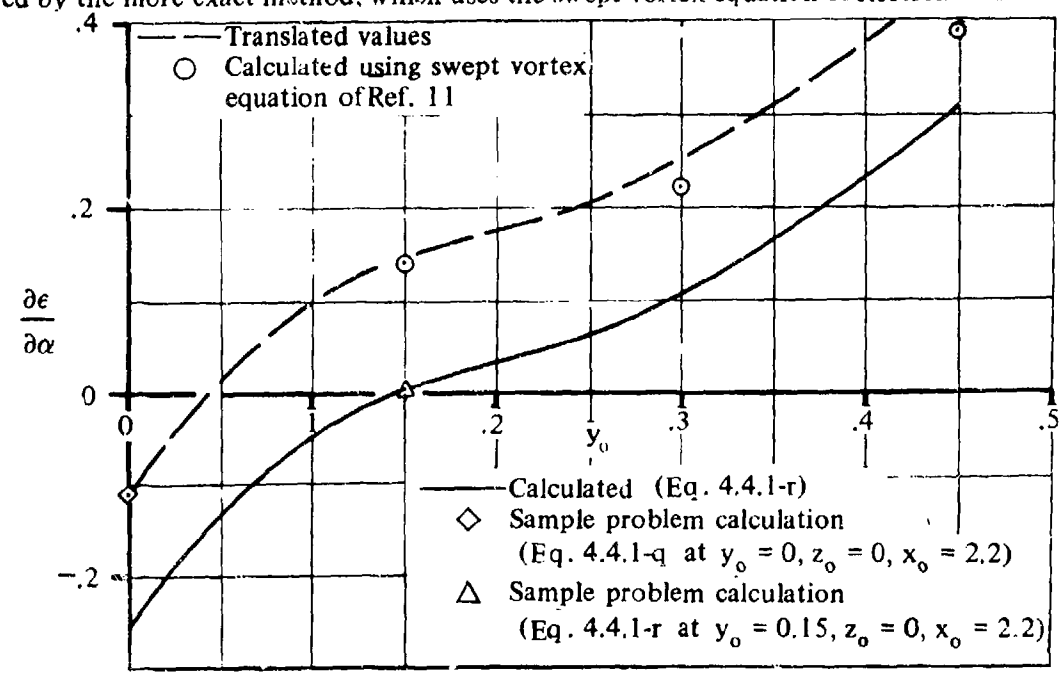
Additional results are presented in Reference 11 for the variation of $\partial\epsilon/\partial\alpha$ in the plane of symmetry with Mach number and longitudinal position. These results are shown in Sketch(i).

SKETCH (i)



The inaccuracies in Method 1 near the trailing edge are not too apparent except for the M = 2.19 curve. As was pointed out previously (Page 4.4.1-28), these inaccuracies may be minimized by determining the exact value at the trailing edge.

Additional results from Reference 11 for the spanwise variation of downwash are shown in Sketch(j). The spanwise variation of downwash at $x_o = 2.2$ and $z_o = 0$, calculated by Equation 4.4.1-r, is shown by the solid curve. This curve is then translated so that the value at $y_o = 0$ coincides with that calculated using Equation 4.4.1-q. The translated values shown by the dashed curve agree reasonably well with values calculated by the more exact method, which uses the swept vortex equation of Reference 11.



SKETCH (j)

2. Supersonic Downwash (Method 2)

Given: A rectangular wing.

Wing Characteristics:

A = 2.31 b = 10.0 ft λ = 1.0 c = 4.33 ft

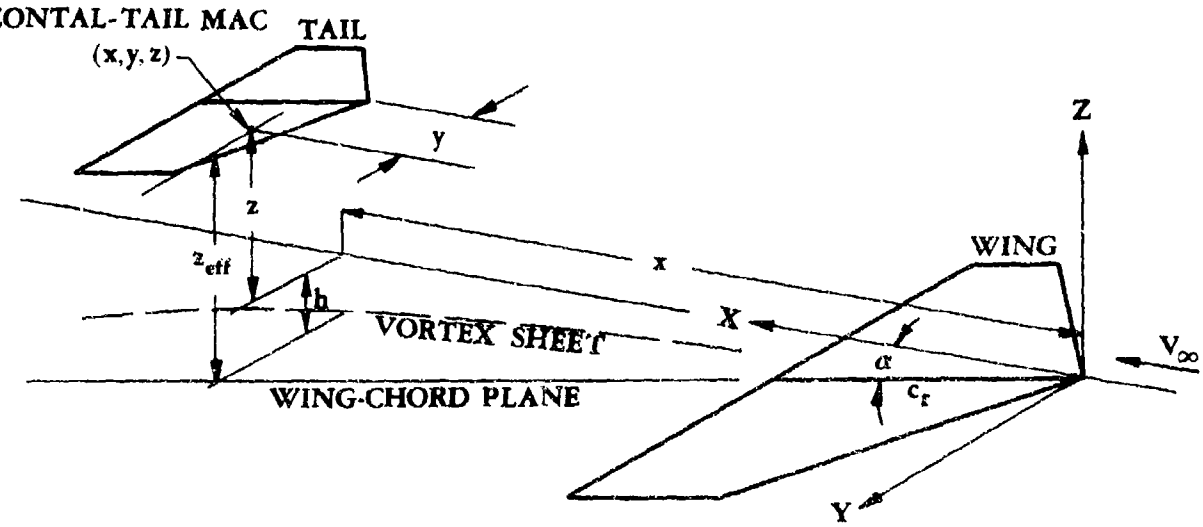
Coordinates of Quarter-Chord of Tail MAC:

x = 15.0 ft y = 1.50 ft z = 1.0 ft

Additional Characteristics:

M = 2.0; β = 1.732 α = 4° = 0.07 rad

QUARTER-CHORD OF THE HORIZONTAL-TAIL MAC



Compute:

$$\frac{2x}{\beta b} = \frac{(2)\,(15)}{(1.732)\,(10)} = 1.73$$

$$\frac{2y}{b} = \frac{(2)\,(1.5)}{10} = 0.30$$

$$\frac{2z}{b} = \frac{(2)\,(1)}{10} = 0.20$$

$$\beta A = (1.732)\,(2.31) = 4.0$$

$$\frac{2h}{\alpha \beta b} = 0.64 \quad \text{(Figure 4.4.1-74d)}$$

$$\left(\frac{2z}{b}\right)_{eff} = \left(\frac{2z}{b}\right) + \left(\frac{2h}{\alpha\beta b}\right)\alpha\beta$$

$$= 0.20 + (0.64)\,(0.07)\,(1.732)$$

$$= 0.28$$

Solution:

$\frac{\partial \bar{\epsilon}}{\partial \alpha}$ is obtained from Figure 4.4.1-76 as $f\left[\frac{2x}{\beta b}, \left(\frac{2z}{b}\right)_{eff}, \frac{2y}{b}, \beta A\right]$

$$\frac{\partial \bar{\epsilon}}{\partial \alpha} = 0.270$$

3. Supersonic Dynamic-Pressure Ratio

Given: The rectangular wing of Reference 15

Wing Characteristics:

$A = 2.0$ $\quad b_W = 8.0$ in. $\quad c_r = \bar{c} = 4.0$ in.

$\Lambda_{c/4} = 0$ $\quad S_W = S_{ref} = 32.0$ in.

Additional Characteristics:

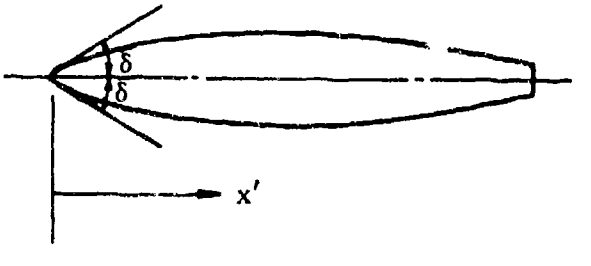
$M_\infty = 2.46;\ \beta = 2.25$ $\quad R_\ell = 1.04 \times 10^6$ (based on $\bar{c}$)

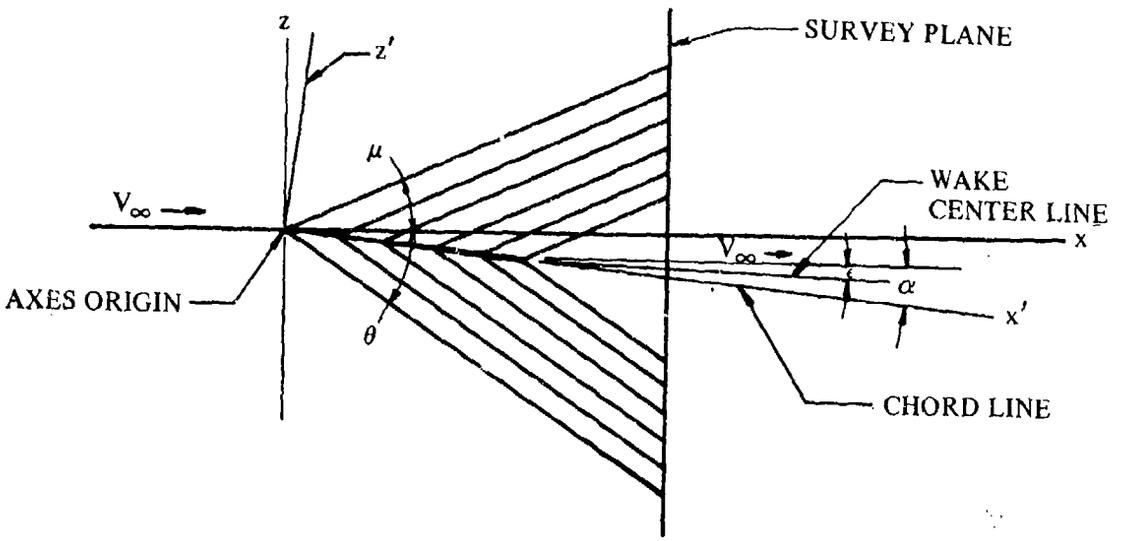
Smooth surface (assume $k = 0$) $\quad$ Survey plane at $x = 6.4$ in.

$\alpha = 6^o$ $\quad C_L = 0.159$ (test value)

Symmetrical airfoil with following characteristics:

Point	x' (in.)	δ (surface slope) (deg)
1 (LE)	0	5.1
2	0.80	3.4
3	1.60	1.0
4	2.40	−0.5
5	3.20	−1.7
6 (TE)	4.00	−2.6





Outside Wake Portion (nonviscous flow field)

Compute:

Determine the flow-deflection angles at the leading edge.

Upper surface

$$\delta'_{LE} = \alpha - \delta_{LE_{upper}} = 6^{o} - 5.1^{o} = 0.9^{o} \text{ (expansion)}$$

Lower surface

$$\delta'_{LE} = -\alpha - \delta_{LE_{lower}} = -6^{o} - 5.1^{o} = -11.1^{o} \text{ (compression)}$$

Determine the values of z on the survey plane (located at $x = 6.4$ in. from the airfoil leading edge) corresponding to x' values of 0, 0.8, 1.6, 2.4, 3.2, and 4.0 (points 1 - 6).

Upper surface (initial expansion angle)

$$\mu = \sin^{-1}\frac{1}{M_{\infty}} = \sin^{-1}\frac{1}{2.46} = 24^{o}$$

$$z = \frac{-x' + x\cos\alpha - \dfrac{x\sin\alpha}{\tan(\mu+\alpha)}}{\sin\alpha + \dfrac{\cos\alpha}{\tan(\mu+\alpha)}} \quad \text{(Equation 4.4.1-w)}$$

$$= \frac{-x' + (6.4)\cos 6^o - \dfrac{(6.4)\sin 6^o}{\tan (24^o + 6^o)}}{\sin 6^o + \dfrac{\cos 6^o}{\tan (24^o + 6^o)}} = \frac{-x'(6.4)(0.9945) - \dfrac{(6.4)(0.1045)}{0.5774}}{0.1045 + \dfrac{0.9945}{0.5774}}$$

$$= 0.5473\,x' + 2.85$$

	x' (in.)	z (in.)	$\frac{z}{b_W/2}$
LE	0	2.850	0.713
	0.8	2.412	0.603
	1.6	1.974	0.494
	2.4	1.536	0.384
	3.2	1.098	0.275
TE	4.0	0.660	0.165

Lower surface (initial compression angle)

θ = 33.5° (Figure 4.4.1-81 at M_∞ = 2.46 and δ' = −11.1°)

$$z = \frac{-x' + x\cos\alpha - \dfrac{x\sin\alpha}{\tan(\alpha - \theta)}}{\sin\alpha + \dfrac{\cos\alpha}{\tan(\alpha - \theta)}} \qquad \text{(Equation 4.4.1-x)}$$

$$= \frac{-x' + (6.4)\cos 6^o - \dfrac{(6.4)\sin 6^o}{\tan (6^o - 33.5^o)}}{\sin 6^o + \dfrac{\cos 6^o}{\tan (6^o - 33.5^o)}} = \frac{-x' + (6.4)(0.9945) - \dfrac{(6.4)(0.1045)}{-0.5206}}{0.1045 + \dfrac{0.9945}{-0.5206}}$$

$$= 0.554\,x' - 4.236$$

	x' (in.)	z (in.)	$\frac{z}{b_W/2}$
LE	0	−4.236	−1.059
	0.8	−3.793	−0.948
	1.6	−3.350	−0.838
	2.4	−2.906	−0.727
	3.2	−2.463	−0.616
TE	4.0	−2.020	−0.505

Determine q/q_∞ at points (x,z) on the survey plane corresponding to points (x',z') on the airfoil.

Upper surface

Point 1 (x' = 0)

$M_\infty = 2.46$

$\Delta\nu_1 = \alpha - \delta_1 = 6^o - 5.1^o = 0.9^o$ (expansion)

$\nu_\infty = 38.2^o$ (Figure 4.4.1-82 at M_∞)

$\nu_1 = \nu_\infty + \Delta\nu_1 = 38.2^o + 0.9^o = 39.1^o$

$M_1 = 2.50$ (Figure 4.4.1-82 at ν_1)

$\left(q/p_t\right)_\infty = 0.264$ (Figure 4.4.1-82 at M_∞)

$\left(q/p_t\right)_1 = 0.256$ (Figure 4.4.1-82 at M_1)

$q_1/q_\infty = \left(q/p_t\right)_1 / \left(q/p_t\right)_\infty = 0.256/0.264 = 0.970$

Point 2 (x' = 0.8 in.)

$\Delta\nu_2 = \delta_1 - \delta_2 = 5.1^o - 3.4^o = 1.7^o$ (expansion)

$\nu_2 = \nu_1 + \Delta\nu_2 = 39.1^o + 1.7^o = 40.8^o$

$M_2 = 2.57$ (Figure 4.4.1-82 at ν_2)

$\left(q/p_t\right)_2 = 0.243$ (Figure 4.4.1-82 at M_2)

$$\frac{q_n}{q_\infty} = \frac{\left(q/p_t\right)_n}{\left(q/p_t\right)_{n-1}} \frac{q_{n-1}}{q_\infty}$$ (Equation 4.4.1-y)

$$\frac{q_2}{q_\infty} = \frac{\left(q/p_t\right)_2}{\left(q/p_t\right)_1} \frac{q_1}{q_\infty} = \frac{0.243}{0.256}(0.970) = 0.921$$

Point 3 ($x' = 1.6$ in.)

$$\Delta\nu_3 = \delta_2 - \delta_3 = 3.4^o - 1.0^o = 2.4^o \text{ (expansion)}$$

$$\nu_3 = \nu_2 + \Delta\nu_3 = 40.8^o + 2.4^o = 43.2^o$$

$$M_3 = 2.68 \quad \text{(Figure 4.4.1-82 at } \nu_3\text{)}$$

$$\left(q/p_t\right)_3 = 0.223 \quad \text{(Figure 4.4.1-82 at } M_3\text{)}$$

$$\frac{q_3}{q_\infty} = \frac{\left(q/p_t\right)_3}{\left(q/p_t\right)_2} \quad \frac{q_2}{q_\infty} = \frac{0.223}{0.243}(0.921) = 0.845 \quad \text{(Equation 4.4.1-y)}$$

Point 4 ($x' = 2.4$ in.)

$$\Delta\nu_4 = \delta_3 - \delta_4 = 1.0^o - (-0.5^o) = 1.5^o \text{ (expansion)}$$

$$\nu_4 = \nu_3 + \Delta\nu_4 = 43.2^o + 1.5^o = 44.7^o$$

$$M_4 = 2.75 \quad \text{(Figure 4.4.1-82 at } \nu_4\text{)}$$

$$\left(q/p_t\right)_4 = 0.211 \quad \text{(Figure 4.4.1-82 at } M_4\text{)}$$

$$\frac{q_4}{q_\infty} = \frac{\left(q/p_t\right)_4}{\left(q/p_t\right)_3} \quad \frac{q_3}{q_\infty} = \frac{0.211}{0.223}(0.845) = 0.800 \quad \text{(Equation 4.4.1-y)}$$

Point 5 ($x' = 3.2$ in.)

$$\Delta\nu_5 = \delta_4 - \delta_5 = -0.5^o - (-1.7^o) = 1.2^o \text{ (expansion)}$$

$$\nu_5 = \nu_4 + \Delta\nu_5 = 44.7^o + 1.2^o = 45.9^o$$

$$M_5 = 2.81 \quad \text{(Figure 4.4.1-82 at } \nu_5\text{)}$$

$$\left(q/p_t\right)_5 = 0.201 \quad \text{(Figure 4.4.1-82 at } M_5\text{)}$$

$$\frac{q_5}{q_\infty} = \frac{\left(q/p_t\right)_5}{\left(q/p_t\right)_4} \quad \frac{q_4}{q_\infty} = \frac{0.201}{0.211}(0.800) = 0.762 \quad \text{(Equation 4.4.1-y)}$$

Point 6 (x' = 4.0 in.)

$$\Delta\nu_6 = \delta_5 - \delta_6 = -1.7^{\circ} - (-2.6^{\circ}) = 0.9^{\circ} \quad \text{(expansion)}$$

$$\nu_6 = \nu_5 + \Delta\nu_6 = 45.9^{\circ} + 0.9^{\circ} = 46.8^{\circ}$$

$$M_6 = 2.85 \quad \text{(Figure 4.4.1-82 at } \nu_6\text{)}$$

$$\left(q/p_t\right)_6 = 0.194 \quad \text{(Figure 4.4.1-82 at } M_6\text{)}$$

$$\frac{q_6}{q_\infty} = \frac{\left(q/p_t\right)_6}{\left(q/p_t\right)_5} \frac{q_5}{q_\infty} = \frac{0.194}{0.201}(0.762) = 0.735 \quad \text{(Equation 4.4.1-y)}$$

Return to free-stream flow at TE (x = 4.0 in.)

Since $M_6 > M_\infty$, the flow is compressed by turning through an oblique shock at the upper surface trailing edge.

$$\delta' = -\alpha + \delta_{TE} = -6^{\circ} + (-2.6^{\circ}) = -8.6^{\circ}$$

$$\theta = 27.2^{\circ} \quad \text{(Figure 4.4.1-81 at } M_6 = 2.85 \text{ and } \delta' = -8.6^{\circ}\text{)}$$

$$\theta + \delta = 27.2^{\circ} - 8.6^{\circ} = 18.6^{\circ}$$

$$M_n = \left[\frac{M_{n-1}^2 \sin^2\theta + 5}{7 M_{n-1}^2 \sin^2\theta - 1}\right]^{1/2} \frac{1}{\sin(\theta + \delta')} \quad \text{(Equation 4.4.1-aa)}$$

$$M_7 = \left[\frac{M_6^2 \sin^2\theta + 5}{7 M_6^2 \sin^2\theta - 1}\right]^{1/2} \frac{1}{\sin(\theta + \delta')}$$

$$= \left[\frac{(2.85)^2 (\sin^2 27.2^{\circ}) + 5}{7(2.85)^2 (\sin^2 27.2^{\circ}) - 1}\right] \frac{1}{\sin(18.6^{\circ})} = 2.46$$

$$\frac{q_n}{q_{n-1}} = \frac{60}{M_{n-1}^2} \frac{\left(1 + 0.2 M_{n-1}^2\right)^{7/2}}{\left(5 + M_{n-1}^2 \sin^2\theta\right)^{5/2}} \quad \text{(Equation 4.4.1-z)}$$

$$\frac{q_7}{q_6} = \frac{60}{M_6^2} \frac{\left(1 + 0.2\, M_6^2\right)^{7/2}}{\left(5 + M_6^2 \sin^2 \theta\right)^{5/2}} = \frac{60}{(2.85)^2} \frac{\left[1 + 0.2(2.85)^2\right]^{7/2}}{\left[5 + (2.85)^2 \left(\sin^2 27.2\right)\right]^{5/2}}$$

$$= \frac{60}{(2.85)^2} \frac{29.28}{116.0} = 1.86$$

$$\frac{q_7}{q_\infty} = \frac{q_7}{q_6} \frac{q_6}{q_\infty} = (1.86)\,(0.735) = 1.367$$

Lower surface

Point 1 ($x' = 0$)

$\Delta\nu_1 = \delta' = -\alpha - \delta_{LE} = -6^\circ - 5.1^\circ = -11.1^\circ$ (compression)

$\theta = 33.5^\circ$ (Figure 4.4.1-81 at $M_\infty = 2.46$ and $\delta' = -11.1^\circ$)

$$\frac{q_n}{q_{n-1}} = \frac{60}{M_{n-1}^2} \frac{\left(1 + 0.2\, M_{n-1}^2\right)^{7/2}}{\left(5 + M_{n-1}^2 \sin^2 \theta\right)^{5/2}}$$ (Equation 4.4.1-z)

$$\frac{q_1}{q_\infty} = \frac{60}{M_\infty^2} \frac{\left(1 + 0.2\, M_\infty^2\right)^{7/2}}{\left(5 + M_\infty^2 \sin^2 \theta\right)^{5/2}} = \frac{60}{(2.46)^2} \frac{\left[1 + 0.2(2.46)^2\right]^{7/2}}{\left[5 + (2.46)^2 (\sin^2 33.5^\circ)\right]^{5/2}}$$

$$= \frac{60}{(2.46)^2} \frac{16.06}{122.5} = 1.300$$

$$M_n = \left[\frac{M_{n-1}^2 \sin^2 \theta + 5}{7\, M_{n-1}^2 \sin^2 \theta - 1}\right]^{1/2} \frac{1}{\sin(\theta + \delta')}$$ (Equation 4.4.1-aa)

$$M_1 = \left[\frac{M_\infty^2 \sin^2 \theta + 5}{7\, M_\infty^2 \sin^2 \theta - 1}\right]^{1/2} \frac{1}{\sin(\theta + \delta')}$$

$$= \left[\frac{(2.46)^2 (\sin^2 33.5^\circ) + 5}{7(2.46)^2 (\sin^2 33.5^\circ) - 1}\right]^{1/2} \frac{1}{\sin[33.5^\circ + (-11.1^\circ)]}$$

$$= (0.758)\,(2.621) = 1.987$$

$\nu_1 = 26.0^\circ$ (Figure 4.4.1-82 at M_1)

$\left(q/p_t\right)_1 = 0.360$ (Figure 4.4.1-82 at M_1)

Point 2 ($x' = 0.8$ in.)

$\Delta\nu_2 = \delta_1 - \delta_2 = 5.1^o - 3.4^o = 1.7^o$ (expansion)

$\nu_2 = \nu_1 + \Delta\nu_2 = 26.0^o + 1.7^o = 27.7^o$

$M_2 = 2.05$ (Figure 4.4.1-82 at ν_2)

$\left(q/p_t\right)_2 = 0.348$ (Figure 4.4.1-82 at M_2)

$$\frac{q_2}{q_\infty} = \frac{\left(q/p_t\right)_2}{\left(q/p_t\right)_1}\frac{q_1}{q_\infty} = \frac{0.348}{0.360}(1.300) = 1.256 \quad \text{(Equation 4.4.1-y)}$$

Point 3 ($x' = 1.6$ in.)

$\Delta\nu_3 = \delta_2 - \delta_3 = 3.4^o - 1.0^o = 2.4^o$ (expansion)

$\nu_3 = \nu_2 + \Delta\nu_3 = 27.7^o + 2.4^o = 30.1^o$

$M_3 = 2.14$ (Figure 4.4.1-82 at ν_3)

$\left(q/p_t\right)_3 = 0.329$ (Figure 4.4.1-82 at M_3)

$$\frac{q_3}{q_\infty} = \frac{\left(q/p_t\right)_3}{\left(q/p_t\right)_2}\frac{q_2}{q_\infty} = \frac{0.329}{0.348}(1.256) = 1.187 \quad \text{(Equation 4.4.1-y)}$$

Point 4 ($x' = 2.4$ in.)

$\Delta\nu_4 = \delta_3 - \delta_4 = 1.0^o - (-0.5^o) = 1.5^o$ (expansion)

$\nu_4 = \nu_3 + \Delta\nu_4 = 30.1^o + 1.5^o = 31.6^o$

$M_4 = 2.20$ (Figure 4.4.1-82 at ν_4)

$\left(q/p_t\right)_4 = 0.317$ (Figure 4.4.1-82 at M_4)

$$\frac{q_4}{q_\infty} = \frac{\left(q/p_t\right)_4}{\left(q/p_t\right)_3}\frac{q_3}{q_\infty} = \frac{0.317}{0.329}(1.187) = 1.141 \quad \text{(Equation 4.4.1-y)}$$

Point 5 ($x' = 3.2$ in.)

$$\Delta\nu_5 = \delta_4 - \delta_5 = -0.5^\circ - (-1.7)^\circ = 1.2^\circ \text{ (expansion)}$$

$$\nu_5 = \nu_4 + \Delta\nu_5 = 31.6^\circ + 1.2^\circ = 32.8^\circ$$

$$M_5 = 2.24 \quad \text{(Figure 4.4.1-82 at } \nu_5\text{)}$$

$$\left(q/p_t\right)_5 = 0.308 \quad \text{(Figure 4.4.1-82 at } M_5\text{)}$$

$$\frac{q_5}{q_\infty} = \frac{\left(q/p_t\right)_5}{\left(q/p_t\right)_4}\frac{q_4}{q_\infty} = \frac{0.308}{0.317}(1.141) = 1.109 \quad \text{(Equation 4.4.1-y)}$$

Point 6 ($x' = 4.0$ in.)

$$\Delta\nu_6 = \delta_5 - \delta_6 = -1.7^\circ - (-2.6)^\circ = 0.9^\circ \text{ (expansion)}$$

$$\nu_6 = \nu_5 + \Delta\nu_6 = 32.8^\circ + 0.9^\circ = 33.7^\circ$$

$$M_6 = 2.28 \quad \text{(Figure 4.4.1-82 at } \nu_6\text{)}$$

$$\left(q/p_t\right)_6 = 0.300 \quad \text{(Figure 4.4.1-82 at } M_6\text{)}$$

$$\frac{q_6}{q_\infty} = \frac{\left(q/p_t\right)_6}{\left(q/p_t\right)_5}\frac{q_5}{q_\infty} = \frac{0.300}{0.308}(1.109) = 1.080 \quad \text{(Equation 4.4.1-y)}$$

Return to free-stream flow at TE ($x = 4.0$ in.)

Since $M_6 < M_\infty$, the flow is expanded at the lower surface trailing edge

$$\Delta\nu_7 = \Delta\nu_{TE} = \alpha + \delta_{TE} = 6^\circ + (-2.6^\circ) = 3.4^\circ$$

$$\nu_7 = \nu_6 + \Delta\nu_7 = 33.7^\circ + 3.4^\circ = 37.1^\circ$$

$$M_7 = 2.41 \quad \text{(Figure 4.4.1-82 at } \nu_7\text{)}$$

$$\left(q/p_t\right)_7 = 0.274 \quad \text{(Figure 4.4.1-82 at } M_7\text{)}$$

$$\frac{q_7}{q_\infty} = \frac{\left(q/p_t\right)_7}{\left(q/p_t\right)_6}\frac{q_6}{q_\infty} = \frac{0.274}{0.300}(1.080) = 0.986 \quad \text{(Equation 4.4.1-y)}$$

The results for q/q_∞ calculated above for the nonviscous flow field are compared with test data in Figure 4.4.1-83. A summary of the above calculations is presented in the following table.

	①	②	③	④	⑤	⑥	⑦	⑧	⑨	⑩
Surface	Point	x' (in.)	$\frac{z}{b_W/2}$	δ (deg)	$\frac{\Delta\nu}{④_{n-1}} - ④$ (deg)	⑤ + ν ⑥$_{n-1}$ (deg)	M (Fig 4.4.1-82)	q/p_t (Fig 4.4.1-82)	$\frac{(q/p_t)_n}{(q/p_t)_{n-1}}$ ⑧/⑧$_{n-1}$	$\frac{q}{q_\infty}$ ⑨ ⑩$_{n-1}$

Inside-Wake Portion (viscous flow field)

Compute:

Determine the half-width of the viscous wake at the survey plane.

Skin-friction drag coefficient

$\ell/k = \infty$; read C_f at give R_ℓ

$C_f = 0.00305$ (Figure 4.1.5.1-26)

Wave-drag coefficient

$\beta \cot \Lambda_{LE_{bw}} = 2.25 \cot (0) > 1$; leading edge is supersonic

$K = 16/3$ (Table, Page 4.1.5.1-16)

$$C_{D_w} = \frac{K}{\beta} \left(\frac{t}{c}\right)^2_{eff} \frac{S_{bw}}{S_{ref}}$$ (Equation 4.1.5.1-k)

$$= \frac{16}{3(2.25)} (0.05)^2 \frac{32.0}{32.0} = 0.00593$$

Zero-lift drag coefficient

$$C_{D_0} = C_{D_f} + C_{D_w} \quad \text{(Equation 4.1.5.1-h)}$$

$$= 0.00305 + 0.00593$$

$$= 0.00898$$

$$\frac{x}{\bar{c}} = \frac{6.4 - 4.0}{4.0} = 0.60 \quad \text{(x measured from wing-root-chord trailing edge)}$$

$$\frac{z_w}{\bar{c}} = 0.68 \sqrt{C_{D_0}\left(\frac{x}{\bar{c}} + 0.15\right)} \quad \text{(Equation 4.4.1-j)}$$

$$= 0.68 \sqrt{0.00898\ (0.60 + 0.15)}$$

$$= 0.0558$$

$$z_w = (0.0558)(\bar{c}) = (0.0558)(4) = 0.223 \text{ in.}$$

Determine the downwash in the plane of symmetry at the vortex sheet (wake center line).

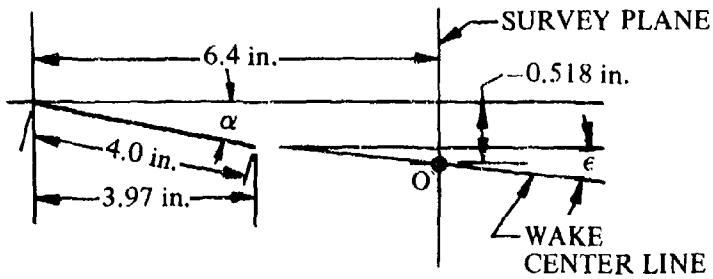
$$\epsilon = \frac{1.62\, C_L}{\pi A} \quad \text{(Equation 4.4.1-k)}$$

$$= \frac{(1.62)(0.159)}{\pi\ 2.0}$$

$$= 0.041 \text{ rad} = 2.35 \text{ deg}$$

Calculate the vertical location, measured from the x-axis, of the intersection of the wake center line and the survey plane.

Distance of origin O below x-axis = $-[4 \sin\alpha + (6.4 - 3.97) \sin\epsilon] = -0.518$ in. In determining the dynamic-pressure ratio in the viscous region, this location is taken as the origin of the vertical distance from the wake center line to the points of interest on the survey plane.



The points in the viscous wake at which the dynamic-pressure ratios are to be calculated are arbitrarily selected. For this example the following points are selected:

$z = 0$	wake center line
$z = \pm 0.08$	within the wake
$z = \pm 0.16$	within the wake
$z = \pm 0.223$	at the edges of the wake

Determine the dynamic-pressure-loss ratio at the wake center.

$$\left(\frac{\Delta q}{q}\right)_o = \frac{2.42\,(C_{D_0})^{1/2}}{\frac{x}{c} + 0.30} \quad \text{(Equation 4.4.1-m)}$$

$$= \frac{(2.42)\,(0.00898)^{1/2}}{0.60 + 0.30} = 0.255$$

Determine the dynamic-pressure-loss ratio for points not on the wake center line.

$$\frac{\Delta q}{q} = \left(\frac{\Delta q}{q}\right)_o \cos^2\left(\frac{\pi}{2}\,\frac{z}{z_w}\right) \quad \text{(Equation 4.4.1-n)}$$

$$= 0.255 \cos^2\left(\frac{\pi}{2}\,\frac{z}{z_w}\right) \text{ (see calculation table below)}$$

Solution: Viscous flow field

$$\frac{q}{q_\infty} = 1 - \frac{\Delta q}{q} \quad \text{(Equation 4.4.1-o)} \quad \text{(see calculation table below)}$$

①	②	③	④	⑤
z (in.) (measured from origin O)	$\frac{z}{z_W}$ ① /0.223	$\frac{\pi}{2}\frac{z}{z_W}$ (rad)	$\Delta q/q$ (Eq. 4.4.1-n) $0.255\cos^2$ ③	q/q_∞ (Eq. 4.4.1-o) 1 - ④
− 0.223	− 1.0	$-\pi/2$	0	1.00
− 0.160	− 0.717	−1.127	0.047	0.953
− 0.080	− 0.359	−0.564	0.182	0.818
0	0	0	0.255	0.745
0.080	0.359	0.564	0.182	0.818
0.160	0.717	1.127	0.047	0.953
0.223	1.0	$\pi/2$	0	1.00

The calculated results for both the nonviscous and viscous flow fields are compared with test data in Figure 4.4.1-83. The results are plotted as a function of $\frac{z}{b_W/2}$, where z is measured from the x-axis. The wake center is at $\frac{z}{b_W/2} = \frac{-0.518}{4.0} = -0.1295$.

4.5 WING-BODY-TAIL COMBINATIONS AT ANGLE OF ATTACK
4.5.1 WING-BODY-TAIL LIFT

4.5.1.1 WING-BODY-TAIL LIFT-CURVE SLOPE

The information contained in this section is for the estimation of the lift-curve slope of wing-body-tail combinations at low angles of attack. In general, it consists of a synthesis of material presented in other sections, although some new information is presented.

The lift-curve slope of typical high-aspect-ratio subsonic aircraft is quite linear up to angles of attack approaching the stall. The lift of the panels is actually linear with angle of attack while the body lift varies as the square of the angle of attack. However, for angles of attack below the stall, the body contribution is small enough so that the lift characteristic of the combination is still sensibly linear. In fact, first-order estimates of lift-curve slope frequently neglect the lift of the body.

When the forward surface has a considerably larger span than the aft surface, the tip vortices shed from the forward panels lie outboard of the aft panels. As a consequence, the integrated effect of the downwash over the aft panel decreases the effectiveness of the aft panel in a linear fashion, and hence the lift-curve slope of the combination still remains linear. This effect is quite constant until the forward panel begins to exhibit flow separation, which distorts the span loading and/or the effective planform. For these types of configurations it is also necessary to assume that the vortex is not fully rolled up (see Paragraph A of Section 4.4.1), and the actual distance between the two surfaces must be taken into account.

When the span of the forward surface is approximately equal to or less than that of the aft surface, the vortex shed from the forward surface interacts directly with the aft surface, generally causing nonlinear lift characteristics at relatively low angle of attack.

A. SUBSONIC

Several methods of estimating the subsonic lift-curve slope of a wing-body-tail combination are available in the Datcom. Two of these methods are presented, differing only in their treatment of the effect of the flow field of the forward surface on the aft surface.

DATCOM METHODS

Method 1

For configurations in which the span of the forward surface is large compared to that of the aft surface, the following approach can be used. For purposes of the Datcom this method is to be used when the ratio of forward- to aft-surface span is 1.5 or greater. The lift-curve slope is given by the equation

$$C_{L_\alpha} = (C_{L_\alpha})'_e [K_N + K_{W(B)} + K_{B(W)}]' \frac{S_e'}{S'} + (C_{L_\alpha})''_e [K_{W(B)} + K_{B(W)}]'' \left(1 - \frac{\partial \bar{\epsilon}}{\partial \alpha}\right) \frac{q''}{q_\infty} \frac{S''}{S'} \frac{S_e''}{S''} \qquad \text{4.5.1.1-a}$$

where

C_{L_α} is the desired lift-curve slope of the wing-body-tail combination.

$(C_{L_\alpha})'_e$ and $(C_{L_\alpha})''_e$ are the lift-curve slopes of the exposed forward and aft surfaces, respectively, from Section 4.1.3.2. (See Section 4.3.1.2 for the definition of exposed surfaces.)

$[K_N + K_{W(B)} + K_{B(W)}]'$ and $[K_{W(B)} + K_{B(W)}]''$ are the appropriate wing-body interference factors from Section 4.3.1.2 for the forward and aft surfaces, respectively.

$\frac{\partial \bar{\epsilon}}{\partial \alpha}$ is the downwash gradient averaged over the aft surface, from Section 4.4.1.

$\frac{q''}{q_\infty}$ is the average dynamic-pressure ratio acting on the aft surface, from Section 4.4.1.

$\frac{S_e'}{S'}$ and $\frac{S_e''}{S''}$ are the ratios of the exposed to gross planform areas of the fore and aft surfaces, respectively.

$\frac{S''}{S'}$ is the ratio of aft to forward gross planform areas.

Equation 4.5.1.1-a is valid only where the aerodynamic parameters are linear. Specifically, the equation is valid for high-aspect-ratio, unswept configurations up to angles of attack approaching the stall. For low-aspect-ratio or swept wings, the applicable angle-of-attack range is considerably less, depending upon the degree of accuracy desired.

Method 2

For configurations in which the spans of the forward and aft surfaces are approximately equal or in which the span of the forward surface is less than that of the aft surface, the following procedure is recommended. The lift-curve slope of the combination is given by the equation

$$C_{L_\alpha} = (C_{L_\alpha})'_e [K_N + K_{W(B)} + K_{B(W)}]' \frac{S_e'}{S'}$$

$$+ (C_{L_\alpha})''_e [K_{W(B)} + K_{B(W)}]'' \frac{q''}{q_\infty} \frac{S''}{S'} \frac{S_e''}{S''} + (C_{L_\alpha})_{W''(V)} \qquad 4.5.1.1\text{-b}$$

where

$$(C_{L_\alpha})_{W''(V)} = \frac{(C_{L_\alpha})'_e \frac{S_e'}{S'} (C_{L_\alpha})''_e \frac{q''}{q_\infty} K_{W(B)}' I_{v_{W'(W'')}} \left(\frac{b''}{2} - \frac{d''}{2}\right)}{2\pi A''_e \left(\frac{b_e'}{2} - \frac{d'}{2}\right)}$$

The parameters in the first two terms on the right-hand side are the same as in equation 4.5.1.1-a. The last term represents the effect of the forward-surface vortices on the aft surface. To obtain the contribution of the last term to the lift-curve slope, refer to Method 3 of Paragraph A in Section 4.4.1. The quantities $(C_{L_\alpha})'_e$ and $(C_{L_\alpha})''_e$ of the last term must be expressed in radians. If the result of this term is desired per degree, the conversion must be applied after the term is evaluated.

Sample Problems

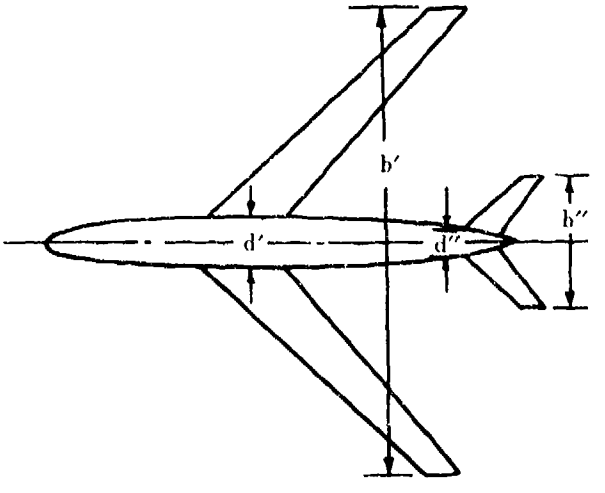
Given:



Wing Characteristics:

Total Panel			Exposed Panel
$A' = 8$	$\lambda' = 0.45$		$A'_e = 7.61$
$\Lambda'_{LE} = 46.3°$	$\Lambda'_{c/4} = 45°$	$\Lambda'_{c/2} = 43.6°$	$\lambda'_e = 0.470$
$i' = 0$	$I'' = 0$		

NACA 63A012 airfoil section

$\alpha'_0 = 0$

Horizontal-Tail Characteristics:

Total Panel			Exposed Panel
$A'' = 4$	$\lambda'' = 0.45$		$A''_e = 3.45$
$\Lambda''_{LE} = 47.6°$	$\Lambda''_{c/4} = 45°$	$\Lambda''_{c/2} = 42.2°$	$\lambda''_e = 0.507$
$i'' = 0$	$\gamma = -3.6°$		

NACA 63A012 airfoil section

The following ratios, based on total panel dimensions:

$\frac{b'}{b''} = 3.536$	$\frac{b'}{d'} = 10.0$	$\frac{b''}{d''} = 4.9$
$\frac{2\ell_a}{b'} = 0.954$	$\frac{\ell_a}{b'} = -0.054$	$\frac{\ell_{eff}}{b'} = 0.120$
$\frac{h_H}{b'} = -0.03$	$\frac{x}{c'} = 3.64$	

The following area ratios:

$\frac{S'_e}{S'} = 0.896$	$\frac{S''_e}{S''} = 0.735$	$\frac{S''}{S'} = 0.160$
$\frac{S_{N_{ref}}}{S'_e} = 0.0701$		

Additional characteristics:

$M = 0.19$	$R = 4 \times 10^6$
$\beta = 0.9818$	smooth surfaces

Note: The above parameters are defined in the sections used to calculate C_{L_α}.

Compute:

Step 1. Lift-curve slopes for the exposed wing and exposed horizontal-tail panels

Exposed wing panel (Section 4.1.3.2)

$c_a = 6.30$ per rad (Section 4.1.1.2) $\qquad \kappa = \frac{c_{\ell_\alpha}}{2\pi} = 1.0$

$\frac{\Lambda'_e}{K}\left[\beta^2 + \tan^2 \Lambda'_{c/2}\right]^{1/2} = 10.41$

$\frac{(C_{L_\alpha})'_e}{A'_e} = 0.500$ per rad (Figure 4.1.3.2-49)

$(C_{L_\alpha})'_e = 0.0664$ per deg

Exposed horizontal-tail panel (Section 4.1.3.2)

$c\ell_\alpha = 6.30$ per rad (Section 4.1.1.2) $\qquad \kappa = \frac{c\ell_\alpha}{2\pi} = 1.0$

$\frac{A''_e}{\kappa}[\beta^2 + \tan^2 \Lambda''_{c/2}]^{1/2} = 4.610$

$\frac{(C_{L_\alpha})''_e}{A''_e} = 0.900$ per rad (Figure 4.1.3.2-49)

$(C_{L_\alpha})''_e = 0.0542$ per deg

Step 2. Wing-body and tail-body interference factors (Section 4.3.1.2)

Wing-body

$(C_{L_\alpha})_N = 2.0$ per rad

$K'_N = \frac{(C_{L_\alpha})_N}{(C_{L_\alpha})'_e}\frac{S_{N_{ref}}}{S'_e} = .037$

$K_{W(B)}' = 1.08$

$K_{B(W)}' = .14$ } Figure 4.3.1.2-10 for $\frac{d'}{b'} = .10$

$[K_N + K_{W(B)} + K_{B(W)}]' = 1.257$

Horizontal-tail-body

$K_{W(B)}'' = 1.170$

$K_{B(W)}'' = .290$ } Figure 4.3.1.2-10 for $\frac{d''}{b''} = .204$

$[K_{W(B)} + K_{B(W)}]'' = 1.460$

Step 3. Downwash parameter (Section 4.4.1)

Obtain value at $\alpha = 0°$

$C_L = 0$ $\qquad \frac{\alpha - \alpha_o}{\alpha_{C_{L_{max}}} - \alpha_o} = 0$

$\frac{A'_{eff}}{A'} = 1.0$

$\frac{b'_{eff}}{b'} = 1.0$ } Figure 4.4.1-66

$A'_{eff} = 8$ $\qquad \left(\frac{\partial \epsilon}{\partial \alpha}\right)_\infty = .23$

$\left(\frac{\partial \epsilon}{\partial \alpha}\right)_{\ell} = .3$ } Figure 4.4.1-67

$\Delta y = 2.65$ (Section 2.2.1)

Type of flow separation: trailing-edge separation is predominant (Figure 4.4.1-68a)

$$\frac{a}{b'} = \frac{h_H}{b'} - \frac{\ell_{eff}}{b'}\left(\alpha - \frac{0.41\,C_L}{\pi A'_{eff}}\right) - \frac{b'_{eff}}{2b'}\tan\Gamma^{v} \quad \text{(Equation 4.4.1-c)}$$

$$\frac{a}{b'} = -0.03$$

$$\frac{b_v}{b'} = \frac{b'_{eff}}{b'} \text{ (at } C_L = 0)$$

$$\frac{b_H}{b_v} = \frac{b''}{b_v} = \frac{b''}{b'}\frac{b'}{b_v} = 0.283$$

$$\frac{2a}{b_v} = 2\frac{a}{b'}\frac{b'}{b_v} = -0.06$$

$$\frac{\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)}{\left(\frac{\partial \epsilon}{\partial \alpha}\right)_v} = 1.0 \text{ (Figure 4.4.1-68b)}$$

$$\frac{\partial \bar{\epsilon}}{\partial \alpha} = \frac{\left(\frac{\partial \bar{\epsilon}}{\partial \alpha}\right)}{\left(\frac{\partial \epsilon}{\partial \alpha}\right)_v}\left(\frac{\partial \epsilon}{\partial \alpha}\right)_v = 0.30$$

$$\left(1 - \frac{\partial \epsilon}{\partial \alpha}\right) = 0.70$$

Step 4. Dynamic-pressure ratio at the horizontal tail (Section 4.4.1)

Obtain value at $\alpha = 0°$

$$\epsilon = 0$$

$$(\gamma + \epsilon - \alpha) = -3.6°$$

$$\frac{z}{\bar{c}'} = \frac{x}{\bar{c}'}\tan(\gamma + \epsilon - \alpha) = -0.229 \text{ (Equation 4.4.1-l)}$$

$C_f = 0.00350$ (Figure 4.1.5.1-26)

$$C_{D_0} = C_f\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]R_{L.S.}\frac{S_{wet}}{S_{ref}} \text{ (Equation 4.1.5.1-a)}$$

$$= 0.0088$$

$$\frac{z_w}{\bar{c}'} = .68\sqrt{C_{D_0}\left(\frac{x}{\bar{c}'} + .15\right)} = .124 \text{ (Equation 4.4.1-j)}$$

$$\frac{z}{z_w} = \frac{z/\bar{c}'}{z_w/\bar{c}'} = -1.85$$

Since $\left|\frac{z}{z_w}\right| \geq 1.0$, $\frac{q''}{q_\infty} = 1.0$

Step 5. Solution for C_{L_α} of wing-body-tail combination

$$C_{L_\alpha} = (C_{L_\alpha})'_e\,[K_N + K_{W(B)} + K_{B(W)}]'\frac{S'_e}{S'} + (C_{L_\alpha})''_e\,[K_{W(B)} + K_{B(W)}]''\left(1 - \frac{\partial \epsilon}{\partial \alpha}\right)\frac{q''}{q_\infty}\frac{S''}{S'}\frac{S_e''}{S''}$$

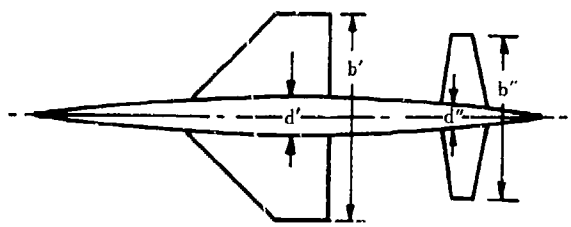
(Equation 4.5.1.1-a)

$C_{L_\alpha} = 0.0748 + 0.0065$

$C_{L_\alpha} = 0.0813$ per deg

2. Method 2

Given:



Wing Characteristics:

	Total Panel		Exposed Panel
$A' = 2$	$\lambda' = 0.33$		$A'_e = 1.80$
$\Lambda'_{LE} = 45°$	$\Lambda'_{c/4} = 36.8°$	$\Lambda'_{c/2} = 26.45°$	$\lambda'_e = 0.378$
$i' = 0$	$\Gamma' = 0$		
NACA 0005 airfoil section			
$\alpha_0 = 0$			

Horizontal-Tail Characteristics:

	Total Panel		Exposed Panel
$A'' = 4.4$	$\lambda'' = 0.46$		$A''_e = 3.82$
$\Lambda''_{LE} = 9.46°$	$\Lambda''_{c/4} = 4.74°$	$\Lambda''_{c/2} = 0$	$\lambda''_e = 0.515$
$i'' = 0$	$\gamma = 0$		
NACA 0005 airfoil section			

The following ratios, based on total panel dimensions:

$\frac{b'}{b''} = 1.278$ $\quad \frac{b'}{d'} = 5.25$ $\quad \frac{b''}{d''} = 5.01$

$\frac{x}{c'} = 1.080$

The following area ratios:

$\frac{S'_e}{S'} = 0.730$ $\quad \frac{S''_e}{S''} = 0.741$ $\quad \frac{S''}{S'} = 0.277$

$\frac{S_{N_{ref}}}{S'_e} = 0.0781$

Additional characteristics:

$M = 0.13$	$R_l = 11.4 \times 10^6$
$\beta = 0.9915$	smooth surface

Compute:

The calculation procedures of Method 2 that are similar to those of Method 1 are not listed in detail here. See sample problem 1 for a detailed presentation.

Step 1. Lift-curve slopes for the exposed wing and exposed horizontal-tail panels (Section 4.1.3.2)

$(C_{L_\alpha})_e' = 0.0405$ per deg

$(C_{L_\alpha})_e'' = 0.0667$ per deg

Step 2. Wing-body and tail-body interference factors (Section 4.3.1.2)

Wing-body

$K_N' = 0.067$ $\quad K_{W(B)}' = 1.16$ $\quad K_{B(W)}' = 0.27$

Tail-body

$K_{W(B)}'' = 1.17$ $\quad K_{B(W)}'' = 0.28$

Step 3. Dynamic-pressure ratio at the horizontal tail (Section 4.4.1)

Obtain at $\alpha = 0$

$$\frac{q''}{q_\infty} = 0.859$$

Step 4. Lift-curve slope of tail section due to wing vortices

$$(C_{L_\alpha})_e' \frac{S_e'}{S'} = .0405\ (.730) = 0.0296 \text{ per deg}$$

$$= 1.696 \text{ per rad}$$

$$(C_{L_\alpha})_e'' \frac{q''}{q_\infty} = .0667\ (.859) = 0.0574 \text{ per deg}$$

$$= 3.28 \text{ per rad}$$

$K_{W(B)}' = 1.16$ $\quad A_e'' = 3.82$

Tail interference factor, $I_{v_{W'(W'')}}$, at $\alpha = 0$

$I_{v_{W'(W'')}} = -3.0$ (sample problem 3, paragraph A, Section 4.4.1)

$\left.\begin{aligned} \frac{b''}{2} - \frac{d''}{2} &= 88.56 \text{ in.} \\ \frac{b_v'}{2} - \frac{d'}{2} &= 89.87 \text{ in.} \end{aligned}\right\}$ also from above sample problem

$$(C_{L_\alpha})_{W''(v)} = \frac{(C_{L_\alpha})_e' \frac{S_e'}{S'} (C_{L_\alpha})_e'' \frac{q''}{q_\infty} K_{W(B)}' I_{v_{W'(W'')}} \left(\frac{b''}{2} - \frac{d''}{2}\right)}{2\pi A_e'' \left(\frac{b_v'}{2} - \frac{d'}{2}\right)}$$

$$= \frac{1.696\ (3.280)\ (1.16)\ (-3.0)\ (88.56)}{2\pi\ (3.82)\ (89.87)}$$

$$= -0.794 \text{ per rad}$$

$$= -0.0139 \text{ per deg}$$

Step 5. Solution for C_{L_α} of wing-body-tail combination

$$C_{L_\alpha} = (C_{L_\alpha})_e' [K_N + K_{W(B)} + K_{B(W)}]' \frac{S_e'}{S'}$$

$$+ (C_{L_\alpha})_e'' [K_{W(B)} + K_{B(W)}]'' \frac{q''}{q_\infty} \frac{S''}{S'} \frac{S_e''}{S''}$$

$$+ (C_{L_\alpha})_{W''(V)}$$

In the above equation the first term represents the wing contribution, including interference effects, and the last two terms represent the tail contribution, including interference effects.

$$C_{L_\alpha} = .0405\ (1.497)\ (.730) + .0667\ (1.450)\ (.859)\ (.277)\ (.741) + (-.0139)$$

$$= 0.0443 + 0.0171 - 0.0139$$

$$= 0.0443 + 0.0032$$

(wing) (tail)

$$C_{L_\alpha} = 0.0475 \text{ per deg}$$

B. TRANSONIC

The estimation of transonic characteristics is one of the nebulous topics of aerodynamics. Variations in the lift-curve slope with Mach number for wing-body-tail configurations at transonic speeds are determined primarily by the wing characteristics, since body characteristics do not change significantly with Mach number. Also the lift-curve slope (at low angles of attack) of the body is generally small compared to that of the lifting surfaces, so that again the low-angle-of-attack lift characteristics can be approximated by the lift of the panels alone. Refinements can be made by applying theoretically derived wing-body interference parameters such as those presented in Section 4.3.1.2, but the improvement in accuracy is questionable.

DATCOM METHOD

It is recommended that the methods presented in Paragraph A above be applied directly to the transonic speed regime. Care should be taken to estimate the lift-curve slope of the isolated lifting panels at the proper Mach number. The interference factors should be obtained from Paragraph C, Section 4.3.1.2.

C. SUPERSONIC

The procedure for estimating the supersonic lift-curve slope of a wing-body-tail combination is essentially identical to that at subsonic speeds. Several methods are presented that depend upon the general arrangement of the configuration.

DATCOM METHODS

Method 1

For configuration in which the forward surface has a span at least 1.5 times the aft-surface span, the lift-curve slope of the configuration can be estimated by using equation 4.5.1.1-a of paragraph A above. Two methods of estimating the interference "K" factors in this equation are presented in Section 4.3.1.2. Two methods of determining the downwash gradient for this type of configuration at supersonic speeds are presented as Methods 1 and 2 in Section 4.4.1.

Method 2

For configurations in which the span of the forward surface is approximately equal to or less than that of the aft surface, equation 4.5.1.1-b of paragraph A is used. For this type of configuration, the trailing vortices of the forward surface strongly interact with the aft surface, and a special accounting must be taken of this situation. Method 3 of Section 4.4.1, which estimates the contribution of this interaction to aft-panel lift, should therefore be used to evaluate the last term of equation 4.5.1.1-b.

4.5.1.2 WING-BODY-TAIL LIFT IN THE NONLINEAR ANGLE-OF-ATTACK RANGE

The lift of wing-body-tail combinations in the nonlinear angle-of-attack range depends primarily on the characteristics of the isolated components. Although little is known about the mutual aerodynamic interference effects in this range, certain reasonable assumptions can be made. First, the wing lift carryover onto the body and the effect of the body upwash on the wing lift are similar in nature to those of the low-angle-of-attack case. These effects, calculated for low angles of attack by slender-body theory, are presented in Section 4.3.1.2.

The effects of the shed vortices are somewhat more involved. For high-aspect-ratio, unswept subsonic configurations, the flow remains attached over the lifting panels up to angles of attack approaching the stall. For this angle-of-attack range, the aerodynamic lift characteristics are linear and the methods of the previous section are adequate. During the stalling process the flow may separate in an infinite variety of ways – depending upon the details of the wing design – each producing a different flow behind the surface and hence a different lift contribution from the aft panel. At present the stalling range of angles of attack is not covered in the Datcom. It can be assumed that above the stall angle of the forward panel the flow from the forward surface does not interact with the aft surface if the aft surface is not directly in the wake, i.e., $\frac{\partial \epsilon}{\partial \alpha} = 0$. For the purposes of the Datcom the wake of a stalled wing can be taken to be bounded by the lines emanating from the leading and trailing edges of the forward surface in the streamwise direction. For aft panels lying within this stall region, the aft-panel contribution to lift is taken to be zero.

For swept and/or low-aspect-ratio configurations, the trailing vortices are shed at progressively more inboard stations as the angle of attack is increased. The effect appears in the downwash field and hence in the lift generated by the aft panel.

The bodies of these configurations lift in a continuous fashion as a function of angle of attack and do not stall in the normal sense. The nonlinear cross-flow contribution to body lift is sizable at the higher angles (near and beyond stall) and should not be neglected. This cross-flow lift is caused by a pair of body vortices that can also strongly affect the lift contributions from the panels. These effects have been accounted for in the Datcom.

A. SUBSONIC

DATCOM METHOD

The lift of a wing-body-tail combination can be estimated at subsonic speeds by using the following equations*:

$$\text{For } \frac{b'}{b''} \geqq 1.5: \quad C_N = \left\{ (C_{N_1}')_o' [K_N + K_{W(B)} + K_{B(W)}]' + (C_{N_2}')_o' [k_{W(B)} + k_{B(W)}]' \right\} \frac{S_o'}{S'}$$

$$+ \left\{ (C_{N_1}')_o'' [K_{W(B)} + K_{B(W)}]'' + (C_{N_2}')_o'' [k_{W(B)} + k_{(B)W}]'' \right\} \frac{q''}{q_\infty} \frac{S_o''}{S'}$$

$$+ I_{r_{B(W')}} \left(\frac{\Gamma}{2\pi a V_r} \right)' \frac{r'}{b_W'/2} \left| \frac{q'}{q_\infty} (C_{L_\alpha})' \alpha' + I_{r_{B(W'')}} \left(\frac{\Gamma}{2\pi a V_r} \right)'' \frac{r''}{b_W''/2} \frac{S''}{S'} \frac{q''}{q_\infty} (C_{L_\alpha})'' \alpha'' \right.$$

4.5.1.2-a

*Note: The limits suggested for b'/b" are quite flexible, depending upon the configuration details and the degree of accuracy desired.

For $\frac{b'}{b''} < 1.5$:

$$C_N = \left\{(C'_{N_1})'_e [K_N + K_{W(B)} + K_{B(W)}]' + (C'_{N_2})'_e [k_{W(B)} + k_{B(W)}]'\right\} \frac{S'_e}{S'}$$

$$+ \left\{(C'_{N_1})''_e [K_{W(B)} + K_{B(W)}]'' + (C'_{N_2})''_e [k_{W(B)} + k_{B(W)}]''\right\} \frac{q''}{q_\infty} \frac{S''_e}{S'}$$

$$+ \frac{(C_{L_\alpha})'_e \frac{S'_e}{S'} (C_{L_\alpha})''_e \frac{q''}{q_\infty} K_{W(B)'} \alpha I_{v_{W'(W'')}} \left(\frac{b''}{2} - \frac{d''}{2}\right)}{2\pi A''_e \left(\frac{b'_v}{2} - \frac{d'}{2}\right) \cos \alpha}$$

$$+ I_{v_{B(W'')}} \left(\frac{\Gamma}{2\pi \alpha Vr}\right)' \frac{r'}{b_{W'}/2} \left| \frac{q'}{q_\infty} (C_{L_\alpha})' \alpha' + I_{vB(W'')} \left(\frac{\Gamma}{2\pi \alpha Vr}\right)'' \frac{r''}{b_{W''}/2} \frac{S''}{S'} \frac{q''}{q_\infty} (C_{L_\alpha})'' \alpha'' \right.$$

4.5.1.2-b

where the primed quantities refer to the forward panel, the double-primed quantities refer to the aft panel, and the subscript e refers to the exposed panel.

$(C'_{N_1})'_e$ is the pseudonormal-force coefficient of the exposed forward panel calculated at the wing angle $\alpha - \alpha'_0$ where α is the angle of attack of the body reference line and α'_0 is the angle, negative in sign, measured from the wing chord line at the MAC to the wing zero-lift line. The value of $(C'_{N_1})'_e$ is obtained from Section 4.1.3.3. (See Section 4.3.1.2 for the definition of exposed panels.)

$(C'_{N_2})'_e$ is the pseudonormal-force coefficient of the exposed forward panel calculated at the wing angle of incidence i' from Section 4.1.3.3. $\left[(C'_{N_2})'_e = 0 \text{ for } i' = 0.\right]$

$(C'_{N_1})''_e$ is the pseudonormal-force coefficient of the exposed aft panel calculated from Section 4.1.3.3 at the angle $\alpha - \epsilon$ for $\frac{b'}{b''} \geq 1.5$ and at α for $\frac{b'}{b''} < 1.5$. The downwash angle ϵ is obtained from Section 4.4.1.

$(C'_{N_2})''_e$ is the pseudonormal-force coefficient of the exposed aft panel calculated from Section 4.1.3.3 at the aft-surface incidence angle i''. $\left[(C'_{N_2})''_e = 0 \text{ for } i'' = 0.\right]$

$(C_{L_\alpha})'_e$ and $(C_{L_\alpha})''_e$ are the lift-curve slopes of the exposed forward and aft panels, respectively, from Section 4.1.3.2.

$(C_{L_\alpha})'$ and $(C_{L_\alpha})''$ are the lift-curve slopes of the forward and aft panels, respectively, from Section 4.1.3.2.

K_N, $K_{W(B)}$, $K_{B(W)}$, $k_{W(B)}$, and $k_{B(W)}$ are the aerodynamic interference factors from Section 4.3.1.2.

$\left[\frac{\Gamma_B}{2\pi Vr\alpha}\right]'$ and $\left[\frac{\Gamma_B}{2\pi Vr\alpha}\right]''$ are nondimensional vortex strenths obtained from Section 4.3.1.3.

$I_{v_{B(W')}}$, $I_{v_{B(W'')}}$, and $I_{v_{W'(W'')}}$ are the vortex interference factors between vehicle components. The values

$I_{v_{B(W')}}$ and $I_{v_{B(W'')}}$ are obtained from Section 4.3.1.3 and $I_{v_{W'(W'')}}$ is obtained from Section 4.4.1.

$\frac{r'}{b'}$ and $\frac{r''}{b''}$ are the ratios of the body radii at the midpoint of the exposed root chord to the total spans of the forward and aft panels, respectively.

α'' is the angle of attack of the aft panel, $\alpha - \epsilon + i''$, where ϵ is obtained from Section 4.4.1.

b'_v is the lateral position of the forward-surface vortex from Section 4.4.1.

$\frac{q''}{q_\infty}$ is the dynamic-pressure ratio due to the forward panel acting on the aft panel. This value is obtained from Section 4.4.1. The value of $\frac{q}{q_\infty}$ is almost always taken to be 1.0.

For configurations in which the body is relatively small compared to the span of the panels, the terms involving $I_{v_{B(W')}}$ and $I_{v_{B(W'')}}$ in equations 4.5.1.2-a and 4.5.1.2-b can be neglected. For purposes of the Datcom these terms are neglected when $b'/(2r)$ or $b''/(2r) \geq 3.0$ (care should be taken to evaluate the coefficients at the proper angles of attack and incidence).

Sample Problems

1. The span of the forward panel is large compared to that of the aft panel ($b'/b'' \geq 1.5$).

Given: Configuration of sample problem 1, paragraph A, Section 4.5.1.1.

Compute:

Step 1. $(C'_{N_1})'_e$ and $(C'_{N_2})'_e$ (Section 4.1.3.3)

From sample problem 1, paragraph A, Section 4.5.1.1

$\alpha'_0 = 0$ $\qquad (C_{L_\alpha})'_e = 0.0664$ per deg $= 3.805$ per rad

$\Delta y = 2.65$

Obtain $(C_{L_{max}})'_e$ and $(\alpha_{C_{L_{max}}})'_e$ (Section 4.1.3.4)

Test for method most applicable

$C_1 = 0.32$ (figure 4.1.3.4-24b)

$$\frac{4}{(C_1 + 1)\cos \Lambda'_{LE}} = 4.386$$

Since $A'_e = 7.61 > 4.386$, use high-aspect-ratio method

$\left(\frac{C_{L_{max}}}{c\ell_{max}}\right)'_e = 0.68$ (figure 4.1.3.4-21a)

$(c\ell_{max})'_e = 1.45$ (Section 4.1.1.4)

$(\Delta C_{L_{max}})'_e = 0$ (figure 4.1.3.4-22)

$(\Delta\alpha_{C_{L_{max}}})'_e = 5.7°$ (figure 4.1.3.4-21b)

$$(C_{L_{max}})'_e = \left[\left(\frac{C_{L_{max}}}{c\ell_{max}}\right) c\ell_{max} + \Delta C_{L_{max}}\right]'_e = 0.986 \quad \text{(equation 4.1.3.4-d)}$$

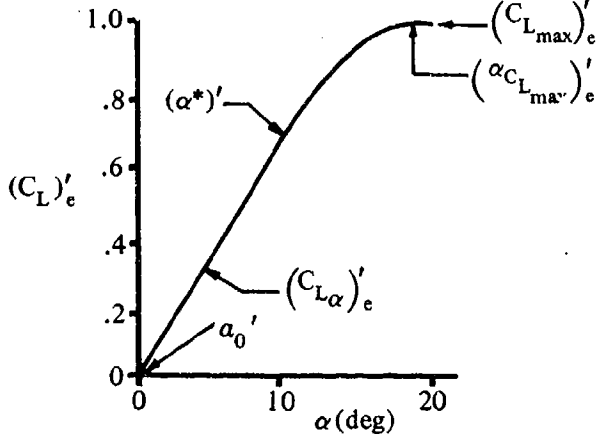
$$(\alpha_{C_{L_{max}}})'_e = \left[\frac{C_{L_{max}}}{C_{L_\alpha}} + \alpha_0 + \Delta\alpha_{C_{L_{max}}}\right]'_e = 20.5° \quad \text{(equation 4.1.3.4-e)}$$

Obtain $(\alpha^*)'$ (Section 4.1.1)

$(\alpha^*)' = 10°$

Construct curve of $(C_L)'_e$ vs α

$(C_L)'_e = (C_{L_\alpha})'_e \alpha$ for α's below $(\alpha^*)'$



From constructed curve, obtain $(C_{N_1})'_e$, substituting the wing angle $\alpha - \alpha_0'$ for α.

$\alpha - \alpha_0' = \alpha - 0 = \alpha$

① α deg	② $\alpha - \alpha_0'$ deg	③ $(C_L)'_e$ at ②	④ $(C_{N_1})'_e = (C_L)'_e/\cos$ ②
0	0	0	0
5	5	.332	.333
10	10	.664	.674
15	15	.915	.947
20.5	20.5	.986	1.053

$(C_{N_2})'_e = 0$, since $i' = 0$

Step 2. Downwash angle at horizontal tail (Section 4.4.1). Sample problem 1, paragraph A, Section 4.5.1.1, has the procedure briefly outlined and sample problem 1, paragraph A, Section 4.4.1, is a detailed example.

The final result is shown below.

α deg	ϵ deg	$\alpha - \epsilon$ deg
0	0	0
5	1.5	3.5
10	2.9	7.1
15	4.9	10.1
20.5	8.0	12.5

Step 3. $(C'_{N_1})''_e$ and $(C'_{N_2})''_e$ (Section 4.1.3.3)

Test for method most applicable (Section 4.1.3.4)

$C_1 = 0.32$ (figure 4.1.3.4-24b)

$$\frac{4}{(C_1 + 1)\cos \Lambda''_{LE}} = 4.494; \quad \frac{3}{(C_1 + 1)\cos \Lambda''_{LE}} = 3.370$$

$A''_e = 3.45$, which lies between the above limits.

Borderline case: use low-aspect-ratio method

$(C_{N_\alpha})''_e = (C_{L_\alpha})''_e = 0.0542$ per deg $= 3.106$ per rad (sample problem 1, paragraph A, Section 4.5.1.1)

Obtain $(C_{L_{max}})''_e$ and $(\alpha_{C_{L_{max}}})''_e$

$$(C_1 + 1)\frac{A''_e}{\beta}\cos \Lambda''_{LE} = 3.13$$

$$\left[(C_{L_{max}})_{base}\right]''_e = 0.80 \text{ (figure 4.1.3.4-23a)}$$

$C_2 = 1.05$ (figure 4.1.3.4-24b)

$(C_2 + 1)\, A''_e \tan \Lambda''_{LE} = 7.75$

$(\Delta C_{L_{max}})''_e = 0.22$ (figure 4.1.3.4-25a)

$$\left[(\alpha_{C_{L_{max}}})_{base}\right]''_e = 22° \text{ (figure 4.1.3.4-25a)}$$

$(\Delta\alpha_{C_{L_{max}}})''_e = 4°$ (figure 4.1.3.4-25b)

$(C_{L_{max}})''_e = [(C_{L_{max}})_{base} + \Delta C_{L_{max}}]''_e = 1.02$ (equation 4.1.3.4-g)

$(\alpha_{C_{L_{max}}})''_e = [(\alpha_{C_{L_{max}}})_{base} + \Delta\alpha_{C_{L_{max}}}]''_e = 26°$ (equation 4.1.3.4-h)

Obtain $[(C_{N_{\alpha\alpha}})_{ref}]''_e$

$$\left[C_{N'} @ C_{L_{max}}\right]''_e = \left(\frac{C_{L_{max}}}{\cos \alpha_{C_{L_{max}}}}\right)''_e = 1.13$$

$$[(C_{N_{\alpha\alpha}})_{ref}]''_e = \frac{\left[C_{N'} @ C_{L_{max}}\right]''_e - (C_{N_\alpha})''_e \frac{\sin 2\alpha}{2}}{\sin \alpha \,|\sin \alpha|} = -0.292 \text{ (equation 4.1.3.3-b, } (C_{N_\alpha})''_e \text{ in rad)}$$

where $\alpha = (\alpha_{C_{L_{max}}})''_e$

Obtain J

$$J = 0.3\,(C_1 + 1)\frac{A''_e}{\beta}\cos \Lambda''_{LE}\left\{(C_1 + 1)\,(C_2 + 1) - \left[\frac{(C_2 + 1)\, A''_e \tan \Lambda''_{LE}}{7}\right]^3\right\} = 1.27$$

Calculate $(C'_{N_1})''_e$ vs α'' (equation 4.1.3.3-a)

① α'' deg	③ $\frac{\tan \alpha''}{\tan (\alpha_{C_{L_{max}}})''_e}$	⑧ $(\Delta C_{N_{\alpha\alpha}})''_e$ figure 4.1.3.3-55a	④ $(C_{N_{\alpha\alpha}})''_e$ $= [(C_{N_{\alpha\alpha}})_{ref} + \Delta C_{N_{\alpha\alpha}}]''_e$	⑤ $(C_{N_{\alpha\alpha}})''_e \sin^2\alpha''$ $= ④ \sin^2\alpha''$	⑥ $(C_{N_\alpha})''_e \frac{\sin 2\alpha''}{2}$ $= 3.106 \frac{\sin 2\alpha''}{2}$	⑦ $(C'_{N_1})''_e$ $= ⑤ + ⑥$
5	.179	1.85	1.558	0.0118	.269	0.281
10	.361	1.85	1.558	0.0468	.531	0.578
15	.550	1.50	1.208	0.081	.777	0.858
20.5	.767	0.75	0.458	0.056	1.019	1.075

Plot $(C'_{N_1})''_e$ vs α and read values at $\alpha - \epsilon$ (since $b'/b'' > 1.5$)

α deg	α'' $(\alpha - \epsilon)$	$(C'_{N_1})''_e$
5	3.5	0.195
10	7.1	0.408
15	10.1	0.583
20.5	12.5	0.720

$(C'_{N_2})''_e = 0$, since $i'' = 0$

Step 4. Wing-body and tail-body interference factors (Section 4.3.1.2)

From sample problem 1, paragraph A, Section 4.5.1.1

$[K_N + K_{W(B)} + K_{B(W)}]' = 1.257$

$[K_{W(B)} + K_{B(W)}]'' = 1.460$

Step 5. Dynamic pressure at horizontal tail (Section 4.4.1)

Sample problem 1, paragraph A, Section 4.5.1.1, has the procedure briefly outlined and sample problem 4, paragraph A, Section 4.4.1, is a detailed example.

The final result is shown below.

$\frac{q''}{q_\infty} = 1.0$ for all α's

(since $\left|\frac{z}{z_W}\right| > 1.0$ for all α's)

Step 6. Vortices effect (Section 4.3.1.3)

$$\frac{b'}{d'} = 10 \qquad \frac{b''}{d''} = 4.9$$

Since these ratios are both greater than 3.0, the vortices effect can be neglected.

$I_{v_{B(W')}} = I_{v_{B(W'')}} = 0$

Step 7. Solution for C_N vs α

$$C_N = \left\{(C'_{N_1})'_e [K_N + K_{W(B)} + K_{B(W)}]' + (C'_{N_2})'_e [k_{W(B)} + k_{B(W)}]'\right\} \frac{S_e'}{S'}$$
$$+ \left\{(C'_{N_1})''_e [K_{W(B)} + K_{B(W)}]'' + (C_{N_2})''_e [k_{W(B)} + k_{B(W)}]''\right\} \frac{q''}{q_\infty} \frac{S_e''}{S'}$$

(equation 4.5.1.2-a simplified)

$C_N = (C'_{N_1})'_e (1.257)(.896) + (C'_{N_1})''_e (1.460)(1.0)(.118)$

$= 1.126 (C'_{N_1})'_e + .1723 (C'_{N_1})''_e$

①	②	③	④	⑤	⑥
α deg	$(C'_{N_1})'_e$	$(C'_{N_1})''_e$	$1.126 (C'_{N_1})'_e$	$.1723 (C'_{N_1})''_e$	$C_N = ④ + ⑤$
0	0	0	0	0	0
5	0.333	0.195	0.375	0.0336	0.4086
10	0.674	0.408	0.759	0.0705	0.8295
15	0.947	0.583	1.066	0.1000	1.166
20.5	1.053	0.720	1.186	0.1240	1.310

2. The span of the forward panel is approximately equal to or less than the span of the aft panel ($b'/b'' < 1.5$).

Given: Configuration of sample problem 2, paragraph A, Section 4.5.1.1.

Compute:

The calculation procedures of sample problem 2 that are similar to those of sample problem 1 are not listed in detail here.

Step 1. $(C'_{N_1})'_\ell$ and $(C'_{N_2})'_\ell$ (Section 4.1.3.3)

The low-aspect-ratio method is used to calculate $(C'_{N_1})'_\ell$.

$(C_{L_{max}})'_\ell = 0.935$ $\qquad$ $(\alpha_{C_{L_{max}}})'_\ell = 26.0°$

$(C_{N_\alpha})'_\ell = 0.0405$ per deg $= 2.32$ per rad $\qquad$ $[(C_{N_{\alpha\alpha}})_{ref}]'_\ell = 0.655$ per rad

$J = 1.60$ $\qquad$ $[C'_N @ C_{L_{max}}]'_\ell = 1.04$

$$(C'_{N_1})'_\ell = (C_{N_\alpha})'_\ell \frac{\sin 2\alpha}{2} + (C_{N_{\alpha\alpha}})'_\ell \sin\alpha \,|\sin\alpha| \quad \text{(equation 4.1.3.3-a)}$$

①	②	③	④	⑤	⑥	⑦
α deg	$\frac{\tan\alpha}{\tan(\alpha_{C_{L_{max}}})'_\ell}$	$(\Delta C_{N_{\alpha\alpha}})'_\ell$ figure 4.1.3.3-55a	$(C_{N_{\alpha\alpha}})'_\ell = [(C_{N_{\alpha\alpha}})_{ref} + \Delta C_{N_{\alpha\alpha}}]'_\ell$	$(C_{N_{\alpha\alpha}})'_\ell \sin^2\alpha$	$(C_{N_\alpha})'_\ell \frac{\sin 2\alpha}{2}$	$(C'_{N_1})'_\ell = ⑤ + ⑥$
5	.179	2.10	2.755	.021	.202	.223
10	.361	2.10	2.755	.083	.397	.480
15	.549	1.80	2.455	.164	.580	.744
20	.746	1.00	1.655	.194	.746	.940
23	.870	.50	1.155	.176	.835	1.011
26	1.0	0	.655	.126	.914	1.040

$(C'_{N_2})'_\ell = 0$, since $i' = 0$

Step 2. $(C'_{N_1})''_\ell$ and $(C'_{N_2})''_\ell$ (Section 4.1.3.4)

Since $\frac{b'}{b''} < 1.5$, evaluate $(C'_{N_1})''_\ell$ at α.

From low-aspect-ratio method, the following is obtained.

$(C_{L_{max}})''_\ell = 0.705$ $\qquad$ $(\alpha_{C_{L_{max}}})''_\ell = 14.5°$

Since $(\alpha_{C_{L_{max}}})''_\ell$ is considerably lower than $(\alpha_{C_{L_{max}}})'_\ell$, the solution for $(C'_{N_1})''_\ell$ must include both below-stall and above-stall calculations. The final result is listed below.

α deg	$(C'_{N_1})''_\ell$
5	.330
10	.625
15	.749
20	.738
23	.767
26	.824

Because of the limitation of the method, the accuracy deteriorates at high angles of attack. Calculate the remaining portion of the solution at $\alpha \leqq 20°$.

$$(C'_{N_2})''_e = 0, \text{ since } i'' = 0$$

Step 3. Wing-body and tail-body interference factors (Section 4.3.1.2)

From sample problem 2, paragraph A, Section 4.5.1.1

$$[K_N + K_{W(B)} + K_{B(W)}]' = 1.497$$

$$[K_{W(B)} + K_{(B)W}]'' = 1.450$$

Step 4. Dynamic pressures at horizontal tail

From the methods of Section 4.4.1 the following is obtained.

α deg	$\frac{q''}{q_\infty}$
0	.859
5	.937
10	.999
15	1.0
20	1.0

Step 5. Vortices effect

$$\frac{b'}{d'} = 5.25 \qquad \frac{b''}{d''} = 5.01$$

Since these ratios are both greater than 3.0, the terms involving $I_{v_{B(W')}}$ and $I_{v_{B(W'')}}$ can be neglected.

Calculate lift of tail due to wing vortices.

From sample problem 2, paragraph A, Section 4.5.1.1

$$(C_{L_\alpha})'_e \frac{S_e'}{S'} = 1.696 \text{ per rad}$$

$$(C_{L_\alpha})''_e \frac{q''}{q_\infty} = 3.28 \text{ per rad (at } \alpha = 0)$$

$$\text{Therefore } (C_{L_\alpha})''_e \frac{q''}{q_\infty} = 3.82 \frac{q''}{q_\infty} \text{ per rad}$$

$$K_{W(B)'} = 1.16$$

$$\frac{\frac{b''}{2} - \frac{d''}{2}}{2\pi A''_e \left(\frac{b_v'}{2} - \frac{d'}{2}\right)} = 0.04106$$

$$C_{L_{W''(v)}} = \frac{(C_{L_\alpha})'_e \frac{S_e'}{S'} (C_{L_\alpha})''_e \frac{q''}{q_\infty} K_{W(B)'} \alpha I_{v_{W'(W'')}} \left(\frac{b''}{2} - \frac{d''}{2}\right)}{2\pi A''_e \left(\frac{b_v'}{2} - \frac{d'}{2}\right)}$$

$$= 1.696 \left(3.82 \frac{q''}{q_\infty}\right) (1.16)\ (0.04106)\ \alpha I_{v_{W'(W'')}}$$

$$= 0.308 \frac{q''}{q_\infty} \alpha I_{v_{W'(W'')}} \ (\alpha \text{ in radians})$$

The variation of $I_{v_{W'(W'')}}$ with α has been calculated in sample problem 3, paragraph A, Section 4.4.1 and is not repeated here.

① α deg	② α rad	③ $I_{v_{W'(W'')}}$	④ $C_{L_{W''(v)}} = 0.308 \frac{q''}{q_\infty}$ ② ③	⑤ $C_{N_{W''(v)}} =$ ④/cos α
0	0	--3.0	0	0
5	0.08725	−2.5	−0.063	−0.063
10	0.1745	−2.0	−0.108	−0.110
15	0.2618	−1.68	−0.135	−0.140
20	0.3490	−1.40	−0.150	−0.160

Step 6. Solution for C_N vs α

$$C_N = \left\{(C_{N_1})'_e [K_N + K_{W(B)} + K_{B(W)}]' + (C'_{N_2})'_e [k_{W(B)} + k_{B(W)}]'\right\} \frac{S'_e}{S'}$$

$$+ \left\{(C'_{N_1})''_e [K_{W(B)} + K_{B(W)}]'' + (C'_{N_2})''_e [k_{W(B)} + k_{B(W)}]''\right\} \frac{q''}{q_\infty} \frac{S''_e}{S'}$$

$$+ C_{N_{W''(v)}} \quad \text{(equation 4.5.1.2-b simplified)}$$

Substituting the constants gives

$$C_N = (C'_{N_1})'_e (1.497)\ (.730) + (C'_{N_1})''_e (1.450) \frac{q''}{q_\infty} (.205) + C_{N_{W''(v)}}$$

$$= 1.093\ (C'_{N_1})'_e + .2973\ (C'_{N_1})''_e \frac{q''}{q_\infty} + C_{N_{W''(v)}}$$

① α deg	② $(C'_{N_1})'_e$	③ $(C'_{N_1})''_e$	④ $\frac{q''}{q_\infty}$	⑤ 1.093 $(C'_{N_1})'_e$	⑥ .2973 $(C'_{N_1})''_e \frac{q''}{q_\infty}$	⑦ $C_{N_{W''(v)}}$	⑧ C_N ⑤ + ⑥ + ⑦
0	0	0	.859	0	0	0	0
5	.223	.330	.937	.244	.092	−0.063	0.265
10	.480	.625	.999	.525	.186	−0.110	0.601
15	.744	.749	1.0	.813	.223	−0.140	0.896
20	.940	.738	1.0	1.027	.219	−0.160	1.086

B. TRANSONIC

At present it is not possible to predict the aerodynamic characteristics of wing-body-tail combinations in the nonlinear angle-of-attack range. However, it is anticipated that the interference effects can be large.

DATCOM METHOD

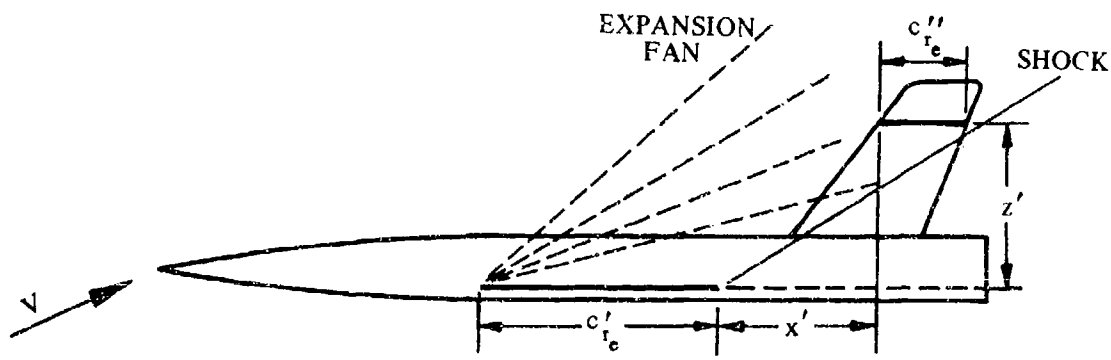
It is recommended that the equations presented in paragraph A above be applied throughout the transonic speed range. Care should be exercised to evaluate the various terms of these equations at the proper Mach number. The interference k factors are most accurate for slender configurations. The 'vortex

terms $I_{v_{B(W')}}$, etc., are thought to be quite valid. But the characteristics of the isolated panels and the downwash cannot be determined as accurately.

C. SUPERSONIC

At supersonic speeds the direct influence of the wing shock-expansion field on the horizontal tail must be considered, as well as the effects of wing vortices and body vortices considered in the subsonic method of paragraph A. The introductory discussion pertaining to body-vortex and wing-vortex effects applies equally as well at subsonic and supersonic speeds.

In cases for which the wing shock-expansion effects are important, account can be taken of the downwash angle, dynamic pressure, and Mach number at the tail by direct application of shock-expansion theory. It is assumed that the flow in the region of the horizontal tail is the two-dimensional shock-expansion field radiating from the exposed root chord of the wing (see sketch (a)). Any effects of wing-body interference or wing section in distorting the shock-expansion field are neglected. This assumption is valid only if the span of the forward surface is greater than the span of the aft surface; i.e., $b' > b''$.



SKETCH (a)

The tail in sketch (a) is in a high downwash field so that the flow at the tail is nearly parallel to the tail chord. As the angle of attack is increased, the tail will move downward with respect to the trailing-edge shock wave, out of the shock-expansion field and into a region of lower downwash. If the tail were initially above the expansion fan from the wing leading edge, an increase in angle of attack would move the tail into the shock-expansion field and, consequently, into a region of increased downwash. It is seen then that the wing shock-expansion field can cause either an increase or a decrease in the tail download in contrast to body vortices and wing vortices, which cause only an increase in tail download.

DATCOM METHOD

The lift of a wing-body-tail combination in the nonlinear angle-of-attack range at supersonic speeds is approximated by using the subsonic method (paragraph A) minus the second term on the right-hand side of the equation,which accounts for the horizontal tail effects, plus an additional term to account for the direct influence of the wing shock-expansion field on the horizontal tail. The influence of the shock-expansion field may be evaluated only for configurations with $b' > b''$. Furthermore, the shock-expansion term presented in the Datcom is applicable only to configurations with neither wing nor tail incidence. In using the method of paragraph A, care should be taken to evaluate all parameters at the proper Mach number.

It should be noted that if the tail is in the wing shock-expansion field, it cannot "see" the wing trailing vortices. In this case, the contribution of the wing-vortex interference (third term of equation 4.5.1.2-b) is

neglected. If, however, the tail is behind the wing shock-expansion field, it can "see" the wing trailing vortices and the wing-vortex interference should be considered rather than the shock-expansion field.

The shock-expansion term for configurations with neither wing nor tail incidence, taken from reference 1*, is

$$\left(\Delta C_L\right)_{SE} = \eta_\alpha \frac{S''}{S'} \alpha C''_{L_\alpha} \qquad 4.5.1.2\text{-c}$$

where all terms except η_α are defined in the subsonic paragraph.

η_α is a "lumped" angle-of-attack effectiveness parameter obtained from figures 4.5.1.2-13a through 4.5.1.2-13p for combinations of angle of attack of 5°, 10°, 15°, and 20° and Mach numbers of 2, 3, 4, and 5. η_α accounts for the change in dynamic pressure at the tail, the change in the tail lift-curve slope, and the downwash at the tail, and is defined as

$$\eta_\alpha = \frac{q''}{q_\infty}\left(1 - \frac{\epsilon}{\alpha}\right)\frac{\left(C''_{L_\alpha}\right)_{M_H}}{\left(C''_{L_\alpha}\right)_{M_\infty}}$$

where

$\left(C''_{L_\alpha}\right)_{M_H}$ is the lift-curve slope of the horizontal tail operating at the local Mach number of the flow in the region of the horizontal tail.

$\left(C''_{L_\alpha}\right)_{M_\infty}$ is the lift-curve slope of the isolated horizontal tail at the free-stream Mach number.

The procedure for using figure 4.5.1.2-13 is as follows:

Step 1. Determine the exposed-wing root chord c_{r_e}' and the exposed-tail root chord c_{r_e}''.

Step 2. Determine the longitudinal distance x' from the trailing edge of the exposed-wing root chord to the leading edge of the exposed-tail root chord, positive for the leading edge of the exposed-tail root chord aft of the trailing edge of the exposed-wing root chord (see sketch (a)).

Step 3. Determine the vertical distance z', measured normal to the longitudinal axis, between the exposed-wing root chord and the exposed-tail root chord, positive for the tail plane above the wing plane (see sketch (a)).

Step 4. Calculate x'/c_{r_e}' and z'/c_{r_e}', and by using these parameters locate the exposed-tail root chord c_{r_e}'' in the proper influence zone of the shock-expansion field of figure 4.5.1.2-13.

*In reference 1, the case of a configuration with tail incidence is analyzed. The shock-expansion term is given by

$$(\Delta C_L)_{SE} = C''_{L_\alpha}\alpha \frac{S''}{S'}\left(\eta_\alpha + \frac{i_W}{\alpha_W}\eta_\delta\right)$$

where η_δ is the tail-incidence effectiveness parameter. Unfortunately, no design charts are available for determining η_δ.

Step 5. The exposed-tail root chord will be divided into several segments by the shock-expansion field. It is assumed that the average value of η_α in the various influence zones is uniform over the tail area within that zone. The average value of η_α in each zone is then multiplied by the ratio of the tail area in that zone to the total exposed tail area S_e' to obtain a weighted value in each zone.

Step 6. Sum the weighted values of η_{l_α} to obtain the total "lumped" effectiveness parameter η_α.

Step 7. Interpolation for angle of attack and/or Mach number may be necessary. If so, a three-point interpolation for α should be made using weighted values of η_α. Two points are sufficient for Mach number interpolation.

For a specified initial Mach number there is a maximum value of the angle of attack for which there exists an oblique-shock solution. Or, conversely, for a specified angle of attack there is a minimum initial Mach number for which there is an oblique-shock solution. The relation between Mach number and angle of attack, below which no solutions for η_α may be obtained, is indicated in sketch (b).

4.5.1.3 WING-BODY-TAIL MAXIMUM LIFT

In this section a general method applicable to all speed regimes is presented for estimating the usable or trimmed maximum lift coefficient for a wing-body-tail configuration with no high-lift devices. The wing-body-tail maximum lift is assumed to occur at the wing-body angle of attack for maximum lift.

The effective tail-body lift component is a direct result of the wing-body pitching moment that must be trimmed. Most conventional clean-wing tail-off configurations exhibit a positive pitching moment at stall, therefore requiring a positive tail lift, which generates a balancing negative pitching moment.

The contribution of the tail lift is only as accurate as the wing-body pitching-moment estimate at stall. Unfortunately, many configurations exhibit nonlinear pitching-moment characteristics at or before stall that effectively prohibit an accurate analytical estimate of the pitching moment at stall. For this reason, it is highly desirable to have pitching-moment test data for the particular configuration or for a similar configuration.

DATCOM METHOD

The wing-body-tail angle of attack at maximum lift is assumed to be identical to the wing-body angle of attack at maximum lift from Section 4.3.1.4.

The following method is based on the wing-body maximum lift plus the tail-body lift that is required to trim the vehicle at $(\alpha_{C_{L_{max}}})_{WB}$. The wing-body-tail maximum lift, based on the wing area S_W and neglecting the vertical-tail drag, is determined by

$$C_{L_{max}} = (C_{L_{max}})_{WB} + C_{L_{H(WBV)}} \qquad 4.5.1.3\text{-a}$$

where

$(C_{L_{max}})_{WB}$ is the wing-body maximum lift from test data or Section 4.3.1.4 at the appropriate speed, based on S_W.

$C_{L_{H(WBV)}}$ is the horizontal-tail lift at $(\alpha_{C_{L_{max}}} - \epsilon)$ in the presence of the wing-body, and vertical tail, based on the wing area S_W. The value of this term is determined from considering the horizontal-tail forces that affect the vehicle pitching moment.

The tail lift can be evaluated using one of the three equations that are presented below. The first equation is complete; whereas, the second and third equations are simplifications of the first equation.

$$C_{L_{H(WBV)}} = \frac{\left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}} + C_{D_H} \cos\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{z_H}{\bar{c}} - C_{D_H} \sin\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{\ell''}{\bar{c}} + C_{m_{H(WBV)}}}{\cos\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{\ell''}{\bar{c}} + \sin\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{z_H}{\bar{c}}}$$

4.5.1.3-b

where

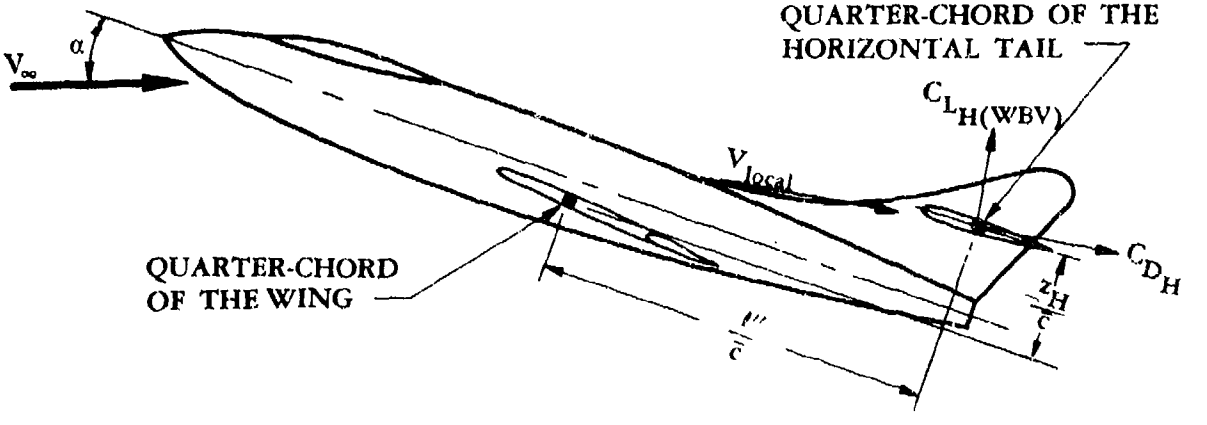
$\left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}}$ is the wing-body pitching moment at the stall angle of attack based on $S_W \bar{c}_W$ with respect to $\bar{c}_W/4$, obtained from test data for the particular configuration. If no test data are available, it is suggested that an approximation be made by using the methods of Sections 4.1.4.2, 4.1.4.3, and 4.3.2.2 in conjunction with test data on a similar configuration.

C_{D_H} is the horizontal-tail-body drag at $\left(\alpha_{C_{L_{max}}} - \epsilon\right)$ based on S_W, obtained from test data or the appropriate methods of Sections 4.3.3.1 and 4.3.3.2.

$\alpha_{C_{L_{max}}}$ is the wing-body angle of attack at stall, obtained from test data or from the appropriate method of Section 4.3.1.4.

ϵ is the wing downwash at the horizontal tail, obtained from test data or the appropriate method of Section 4.4.1.

$\frac{z_H}{\bar{c}}$ is the ratio of the height of the quarter-chord point of the horizontal-tail MAC above the quarter-chord point of the wing MAC, to the wing MAC. The height is measured perpendicular to the longitudinal axis and is positive for the horizontal tail above the wing (see Sketch (a)).



SKETCH (a)

$\frac{\ell''}{\bar{c}}$ is the ratio of the distance from the quarter-chord point of the wing MAC to the quarter-chord point of the horizontal panel MAC (measured parallel to the longitudinal axis), to the wing MAC (see Sketch (a)).

$C_{m_{H(WBV)}}$ is the horizontal-tail pitching moment at $\left(\alpha_{C_{L_{max}}} - \epsilon\right)$ based on $S_W \bar{c}_W$ with respect to the quarter-chord point of the horizontal-tail MAC obtained from test data. If no test data are available, it is suggested that an approximation be made by using the methods from Sections 4.1.4.2, 4.1.4.3, and 4.3.2.2 in conjunction with test data on a similar configuration. However, for horizontal tails with symmetrical airfoil sections, this term can be neglected.

For those configurations where the horizontal-tail drag is very small in comparison with the wing-body pitching moment, the drag terms of Equation 4.5.1.3-b can be omitted. In addition, since most horizontal tails have symmetrical airfoil sections, the $C_{m_{H(WBV)}}$ term can also be omitted. Thus Equation 4.5.1.3-b can be written as

$$C_{L_{H(WBV)}} = \frac{\left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}}}{\cos\left(\alpha_{C_{L_{max}}} - \epsilon\right)\frac{\ell''}{\bar{c}} + \sin\left(\alpha_{C_{L_{max}}} - \epsilon\right)\frac{z_H}{\bar{c}}} \qquad 4.5.1.3\text{-c}$$

If the small-angle approximation can be justified for $\left(\alpha_{C_{L_{max}}} - \epsilon\right)$, the above can be further simplified to yield

$$C_{L_{H(WBV)}} = \frac{\left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}}}{\frac{\ell''}{\bar{c}}} \qquad 4.5.1.3\text{-d}$$

No substantiation is presented because of the lack of test data on wing-body-tail configurations.

Sample Problem

Given:

$\left(C_{L_{max}}\right)_{WB} = 1.0$ $\quad \alpha_{C_{L_{max}}} = 16.5^{o}$ $\quad \epsilon = 9.2^{o}$ $\quad \left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}} = 0.10$

$C_{D_H} = 0.02$ $\quad C_{m_{H(WBV)}} = 0$ $\quad \frac{\ell''}{\bar{c}} = 2.75$ $\quad \frac{z_H}{\bar{c}} = 1.23$

Compute:

$$C_{L_{H(WBV)}} = \frac{\left(C_{m_{WB}}\right)_{\alpha_{C_{L_{max}}}} + C_{D_H} \cos\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{z_H}{\bar{c}} - C_{D_H} \sin\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{\ell''}{\bar{c}} + C_{m_{H(WBV)}}}{\cos\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{\ell''}{\bar{c}} + \sin\left(\alpha_{C_{L_{max}}} - \epsilon\right) \frac{z_H}{\bar{c}}}$$

(Equation 4.5.1.3-b)

$$= \frac{0.10 + 0.02 \cos (16.5^\circ - 9.2^\circ) (1.23) - 0.06 \sin (16.5^\circ - 9.2^\circ) (2.75) + 0}{\cos (16.5^\circ - 9.2^\circ) (2.75) + \sin (16.5^\circ - 9.2^\circ) (1.23)}$$

$$= \frac{0.10 + (0.02) (0.9919) (1.23) - (0.06) (0.1271) (2.75)}{(0.9919) (2.75) + (0.1271) (1.23)}$$

$$= \frac{0.1034}{2.884}$$

$$= 0.0359$$

Solution:

$$C_{L_{max}} = (C_{L_{max}})_{WB} + C_{L_{H(WBV)}} \quad \text{(Equation 4.5.1.3-a)}$$

$$= 1.0 + 0.036$$

$$= 1.036$$

4.5.2 WING-BODY-TAIL PITCHING MOMENT

4.5.2.1 WING-BODY-TAIL PITCHING-MOMENT-CURVE SLOPE

Pitching-moment-estimation methods are inherently less accurate than those for lift, since pitching moment is dependent primarily on load distribution, while lift depends primarily on gross forces. Many of the comments on lift given in Section 4.5.1.1 are also applicable to this Section.

A. SUBSONIC

DATCOM METHODS

Two methods are presented, differing in their treatment of the effect of the forward-surface flow field on the aft surface.

Method 1 ($b'/b'' \geq 1.5$)

For configurations in which the span of the forward surface is large compared to that of the aft surface, the following approach can be used. This method is to be used when the ratio of the forward- to the aft-surface span is 1.5 or greater. The complete equation for the pitching-moment-curve slope C_{m_α} of a wing-body-tail configuration based on the gross area and MAC of the forward panel and an arbitrary center-of-gravity position is given by

$$C_{m_\alpha} = -\frac{x_{cg} - x'}{\bar{c}'}\left[\left\{-(C_L)' + (C_{D_\alpha})'\right\}\sin\alpha + \left\{(C_{L_\alpha})' + (C_D)'\right\}\cos\alpha\right]$$

$$-\frac{z_{cg} - z'}{\bar{c}'}\left[\left\{(C_{L_\alpha})' + (C_D)'\right\}\sin\alpha + \left\{(C_L)' - (C_{D_\alpha})'\right\}\cos\alpha\right]$$

$$-\frac{x_{cg} - x''}{\bar{c}''}\left[\left\{-(C_L)'' + (C_{D_\alpha})''\right\}\sin(\alpha-\epsilon) + \left\{(C_{L_\alpha})'' + (C_D)''\right\}\cos(\alpha-\epsilon)\right]\frac{q''}{q_\infty}\frac{S''}{S'}\frac{\bar{c}''}{\bar{c}'}\left(1 - \frac{\partial\epsilon}{\partial\alpha}\right)$$

$$-\frac{z_{cg} - z''}{\bar{c}''}\left[\left\{(C_{L_\alpha})'' + (C_D)''\right\}\sin(\alpha-\epsilon) + \left\{(C_L)'' - (C_{D_\alpha})''\right\}\cos(\alpha-\epsilon)\right]\frac{q''}{q_\infty}\frac{S''}{S'}\frac{\bar{c}''}{\bar{c}'}\left(1 - \frac{\partial\epsilon}{\partial\alpha}\right)$$

where

geometric parameters are defined in figure 4.5.2.1-7 (note that g', g'', and ℓ'' are always positive)

primed quantities pertain to the forward panel

double-primed quantities pertain to the aft panel

the lift and drag terms below are calculated by the methods of Sections 4.3.1.2 and 4.3.3.2, respectively

$(C_L)'$ and $(C_D)'$ are the complete lift and drag coefficients of the forward panel and body, including wing-body interference. The coefficients are evaluated at the angle $\alpha - \alpha_0 + i'$.

$(C_{L_\alpha})'$ and $(C_{D_\alpha})'$ are the complete lift-curve and drag-curve slopes of the forward panel and body including interferences.

$(C_L)''$ and $(C_D)''$ are the lift and drag coefficients of the aft panel evaluated at the tail angle of attack $\alpha'' = \alpha - \epsilon + i''$. These coefficients include wing-body interferences.

$(C_{L_\alpha})''$ and $(C_{D_\alpha})''$ are the lift-curve and drag-curve slopes of the aft panel including wing-body interference effects.

ϵ and $\frac{\partial\epsilon}{\partial\alpha}$ are the downwash angle and downwash gradient, respectively, from Section 4.4.1

α'' is the angle of attack of the aft panel, $\alpha - \epsilon + i''$, where ϵ is the average downwash angle (Section 4.4.1) acting on the aft panel evaluated at the forward-panel angle of attack $\alpha - \alpha_0 + i'$

$$\frac{x_{cg} - x'}{\bar{c}'} = \frac{x_{cg}}{\bar{c}'} + \left(\frac{x_{ac}'}{c_r'}\right)\left(\frac{c_r'}{\bar{c}'}\right) - \frac{g'}{\bar{c}'} - .25 \qquad 4.5.2.1\text{-b}$$

$$\frac{x_{cg} - x''}{\bar{c}''} = \frac{\ell''}{\bar{c}''} + \frac{x_{cg}}{\bar{c}''} + \left(\frac{x_{ac}''}{c_r''}\right)\left(\frac{c_r''}{\bar{c}''}\right) - \frac{g''}{\bar{c}''} - .25 \qquad 4.5.2.1\text{-c}$$

$x'_{a.c.}$ is the aerodynamic center of the forward panel obtained from Section 4.3.2.2 (referred to the forward-panel apex and based on exposed panel geometry)

$x''_{a.c.}$ is the aerodynamic center of the aft panel obtained from Section 4.3.2.2 (referred to the aft-panel apex and based on exposed panel geometry)

For most configurations the terms involving z_{cg} are negligible, and frequently the drag terms are small enough to be negligible. If, in addition, the usual approximations for small angle of attack are made, equation 4.5.2.1-a can be simplified to give

$$C_{m_\alpha} = -\frac{x_{cg} - x'}{\bar{c}'}(C_{L_\alpha})' - \frac{x_{cg} - x''}{\bar{c}''}(C_{L_\alpha})''\frac{q''}{q_\infty}\frac{S''}{S'}\frac{\bar{c}''}{\bar{c}'}\left(1 - \frac{\partial \epsilon}{\partial \alpha}\right) \qquad 4.5.2.1\text{-d}$$

which can be written as

$$C_{m_\alpha} = -\frac{x_{cg} - x'}{\bar{c}'}[K_N + K_{B(W)} + K_{W(B)}]'\,(C_{L_\alpha})'_e\frac{S_e'}{S'}$$

$$-\frac{x_{cg} - x''}{\bar{c}''}[K_{B(W)} + K_{W(B)}]''\,(C_{L_\alpha})''_e\left(1 - \frac{\partial \epsilon}{\partial \alpha}\right)\frac{q''}{q_\infty}\frac{S_e''}{S''}\frac{S''}{S'}\frac{\bar{c}''}{\bar{c}'} \qquad 4.5.2.1\text{-d}'$$

where

$$\frac{x_{cg} - x'}{\bar{c}'} = \frac{x_{cr}}{\bar{c}'} + \left(\frac{x_{ac}'}{c_r'}\right)\left(\frac{c_r'}{\bar{c}'}\right) - \frac{g'}{\bar{c}'} - .25 \quad \text{(equation 4.5.2.1-b)}$$

$$\frac{x_{cg} - x''}{\bar{c}''} = \frac{l''}{\bar{c}''} + \frac{x_{cg}}{\bar{c}''} \qquad 4.5.2.1\text{-e}$$

and the remaining terms are defined in Section 4.5.1.1.

Method 2 $(b'/b'') < 1.5$

For configurations in which the span of the forward surface is approximately equal to or less than that of the aft surface, the vortex shed from the forward surface interacts directly with the aft surface and the resulting interference effects must be accounted for in the tail terms. This method is to be used when the ratio of the forward- to the aft-surface span is less than 1.5. The contribution of this interference effect to the drag coefficient is not given in literature. However, by making the assumptions that led to equation 4.5.2.1-d, a simplified expression for the pitching-moment-curve slope of a complete wing-body-tail configuration based on the gross area and MAC of the forward panel and an arbitrary center-of-gravity position is:

$$C_{m_\alpha} = -\frac{x_{cg} - x'}{\bar{c}'}(C_{L_\alpha})' - \frac{x_{cg} - x''}{\bar{c}''}\left(\frac{\bar{c}''}{\bar{c}'}\right)\left[(C_{L_\alpha})''\frac{S''}{S'}\frac{q''}{q_\infty} + (C_{L_\alpha})_{W''(v)}\right] \qquad 4.5.2.1\text{-f}$$

Equation 4.5.2.1-f can be written as

$$C_{m_\alpha} = -\frac{x_{cg} - x'}{\bar{c}'}[K_N + K_{(B)W} + K_{W(B)}]'\,(C_{L_\alpha})'_e\frac{S_e'}{S'}$$

$$-\frac{x_{cg} - x''}{\bar{c}''}\left(\frac{\bar{c}''}{\bar{c}'}\right)\left\{[K_{W(B)} + K_{B(W)}]''\,(C_{L_\alpha})''_e\frac{S_e''}{S''}\frac{S''}{S'}\frac{q''}{q_\infty} + (C_{L_\alpha})_{W''(v)}\right\} \qquad 4.5.2.1\text{-f}'$$

where

$\frac{x_{cg} - x'}{\bar{c}'}$ is given by equation 4.5.2.1-b

$\frac{x_{cg} - x''}{\bar{c}''}$ is given by equation 4.5.2.1-e

$(C_{L_\alpha})_{W''(v)}$ is the effect of the forward-surface vortices on the aft surface as defined in Section 4.5.1.1 and the remaining terms are defined in Section 4.5.1.1.

Sample Problems

1. Method 1 ($b'/b'' \geq 1.5$)

Given:

Configuration of sample problem 1, paragraph A, Section 4.5.1.1. Additional characteristics are based on total-panel dimensions.

c.g. at $\frac{\bar{c}'}{4}$

$\frac{c_r'}{\bar{c}'} = 1.316$ $\qquad$ $\frac{\bar{c}''}{\bar{c}'} = 0.566$

$\frac{g'}{\bar{c}'} = 1.745$ $\qquad$ $\frac{\ell''}{\bar{c}''} = 5.30$

$\left(\frac{x_{ac}}{c_r}\right)_N = -0.783$

$\left(\frac{x_{ac}}{c_r}\right)_{W(B)} = 1.650$ } From Section 4.3.2.2; functions of wing-body geometry

$\left(\frac{x_{ac}}{c_r}\right)_{B(W)} = 0.822$

Compute:

Step 1. $\frac{x_{ac}'}{c_r'}$

From Section 4.3.1.2:

$$(C_{L_\alpha})_N = K_N' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

$$(C_{L_\alpha})_{W(B)} = K_{W(B)}' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

$$(C_{L_\alpha})_{B(W)} = K_{B(W)}' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

The above parameters have been calculated in sample problem 1, paragraph A, Section 4.5.1.1.

$(C_{L_\alpha})_e' \frac{S_e'}{S'} = .0664\ (.896) = .0595$ per deg

$(C_{L_\alpha})_N = 0.037\ (.0595) = 0.0022$ per deg

$(C_{L_\alpha})_{W(B)} = 1.08\ (.0595) = 0.0643$ per deg

$(C_{L_\alpha})_{B(W)} = 0.14\ (.0595) = 0.0083$ per deg

From Section 4.3.2.2:

$$\frac{x_{ac}'}{c_r'} = \frac{\left(\frac{x_{ac}}{c_r}\right)_N (C_{L_\alpha})_N + \left(\frac{x_{ac}}{c_r}\right)_{W(B)} (C_{L_\alpha})_{W(B)} + \left(\frac{x_{ac}}{c_r}\right)_{B(W)} (C_{L_\alpha})_{B(W)}}{(C_{L_\alpha})_N + (C_{L_\alpha})_{W(B)} + (C_{L_\alpha})_{B(W)}} \quad \text{(equation 4.3.2.2-a)}$$

$$= \frac{-.783\ (.0022) + 1.650\ (.0643) + .822\ (.0083)}{0.0022 + 0.0643 + 0.0083}$$

$$= 1.49$$

Step 2. $\frac{x_{cg} - x'}{\bar{c}'}$ and $\frac{x_{cg} - x''}{\bar{c}''}$

$$\frac{x_{cg}}{\bar{c}'} = 0$$

$$\frac{x_{cg} - x'}{\bar{c}'} = \frac{x_{cg}}{\bar{c}'} + \left(\frac{x_{ac}'}{c_r'}\right)\left(\frac{c_r'}{\bar{c}'}\right) - \frac{g'}{\bar{c}'} - .25 \quad \text{(equation 4.5.2.1-b)}$$

$$= 0 + 1.49\ (1.316) - 1.745 - .25$$

$$= -0.034$$

$$\frac{x_{cg} - x''}{\bar{c}''} = \frac{l''}{\bar{c}''} + \frac{x_{cg}}{\bar{c}''} = 5.30 \quad \text{(equation 4.5.2.1-e)}$$

Step 3. Solution for C_{m_α}

$(C_{L_\alpha})'$ and $(C_{L_\alpha})''$ have been calculated in sample problem 1, paragraph A, Section 4.5.1.1.

$(C_{L_\alpha})' = 0.0748$ per deg

$(C_{L_\alpha})'' \frac{q''}{q_\infty} \frac{S''}{S'}\left(1 - \frac{\partial \epsilon}{\partial \alpha}\right) = 0.0065$ per deg (this value includes wake and wash effects calculated in referenced problem)

$$C_{m_\alpha} = -\frac{x_{cg} - x'}{\bar{c}'}(C_{L_\alpha})' - \frac{x_{cg} - x''}{\bar{c}''}(C_{L_\alpha})'' \frac{q''}{q_\infty} \frac{S''}{S'} \frac{\bar{c}''}{\bar{c}'}\left(1 - \frac{\partial \epsilon}{\partial \alpha}\right) \quad \text{(equation 4.5.2.1-d)}$$

$$= -(-.034)\ (.0748) - (5.30)\ (.566)\ (.0065)$$

$$= 0.0025 - 0.0195$$

$$= -0.0170 \text{ per deg}$$

2. Method 2 ($b'/b'' < 1.5$)

Given:

Configuration of sample problem 2, paragraph A, Section 4.5.1.1. Additional characteristics are based on total panel dimensions.

e.g. at $\frac{\bar{c}'}{4}$

$$\frac{c_r'}{\bar{c}'} = 1.38 \qquad \frac{\bar{c}''}{\bar{c}'} = 0.343 \qquad \frac{g'}{\bar{c}'} = 0.389 \qquad \frac{l''}{\bar{c}''} = 5.32$$

$\left(\frac{x_{ac}}{c_r}\right)_N = -0.333$

$\left(\frac{x_{ac}}{c_r}\right)_{W(B)} = 0.526$

$\left(\frac{x_{ac}}{c_r}\right)_{B(W)} = 0.356$

} From Section 4.3.2.2; functions of wing-body geometry

Compute:

Step 1. $\frac{x_{ac}'}{c_r'}$:

From Section 4.3.1.2:

$$(C_{L_\alpha})_N = K_N' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

$$(C_{L_\alpha})_{W(B)} = K_{W(B)}' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

$$(C_{L_\alpha})_{B(W)} = K_{B(W)}' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

The above parameters have been calculated in sample problem 2, paragraph A, Section 4.5.1.1.

$$(C_{L_\alpha})_e' \frac{S_e'}{S'} = (0.0405)\ (0.730) = 0.0296 \text{ per deg}$$

$$(C_{L_\alpha})_N = (0.67)\ (0.0296) = 0.0198 \text{ per deg}$$

$$(C_{L_\alpha})_{W(B)} = (1.16)\ (0.0296) = 0.0343 \text{ per deg}$$

$$(C_{L_\alpha})_{B(W)} = (0.27)\ (0.0296) = 0.0080 \text{ per deg}$$

$$\frac{x_{ac}'}{c_r'} = \frac{\left(\frac{x_{ac}}{c_r}\right)_N (C_{L_\alpha})_N + \left(\frac{x_{ac}}{c_r}\right)_{W(B)} (C_{L_\alpha})_{W(B)} + \left(\frac{x_{ac}}{c_r}\right)_{B(W)} (C_{L_\alpha})_{B(W)}}{(C_{L_\alpha})_N + (C_{L_\alpha})_{W(B)} + (C_{L_\alpha})_{B(W)}} \quad \text{(equation 4.3.2.2-a)}$$

$$= \frac{(-0.333).\ (0.0198) + (0.526)\ (0.0343) + (0.356)\ (0.0080)}{0.0198 + 0.0343 + 0.008}$$

$$= 0.230$$

Step 2. $\frac{x_{cg} - x'}{\bar{c}'}$ and $\frac{x_{cg} - x''}{\bar{c}''}$:

$$\frac{x_{cg}}{\bar{c}'} = 0$$

$$\frac{x_{cg} - x'}{\bar{c}'} = \frac{x_{cg}}{\bar{c}'} + \left(\frac{x_{ac}'}{c_r'}\right)\left(\frac{c_r'}{\bar{c}'}\right) - \frac{g'}{\bar{c}'} - .25 \quad \text{(equation 4.5.2.1-b)}$$

$$= 0 + (0.230)\ (1.38) - 0.389 - .25$$

$$= -0.3216$$

$$\frac{x_{cg} - x''}{\bar{c}''} = \frac{l''}{\bar{c}''} + \frac{x_{cg}}{\bar{c}''} \quad \text{(equation 4.5.2.1-e)}$$

$$= 5.32$$

Step 3. Solution for C_{m_α}:

$$C_{m_\alpha} = \frac{x_{cg} - x'}{\bar{c}'} [K_N + K_{W(B)} + K_{B(W)}]' (C_{L_\alpha})_e' \frac{S_e'}{S'}$$

$$- \frac{x_{cg} - x''}{\bar{c}''} \left(\frac{\bar{c}''}{\bar{c}'}\right) \left\{ [K_{W(B)} + K_{B(W)}]'' (C_{L_\alpha})_e'' \frac{S_e''}{S''} \frac{S''}{S'} \frac{q''}{q_\infty} + (C_{L_\alpha})_{W''(V)} \right\} \quad \text{(equation 4.5.2.1-f')}$$

Using the above results and the parameters calculated in sample problem 2, par graph A, Section 4.5.1.1 gives

$$C_{m_\alpha} = -(-0.3216)\ (1.497)\ (0.0405)\ (0.730)$$
$$-\ (5.32)\ (0.343)\ [(1.45)\ (0.0667)\ (0.741)\ (0.277)\ (0.859) + (-0.0139)]$$
$$= 0.0085 \text{ per deg}$$

B. TRANSONIC

At transonic speeds the mutual interferences that exist between components can have pronounced effects upon the pitching-moment characteristics of wing-body-tail combinations. The sensitivity of shock-wave position and strength to minor configuration changes and the common occurrence of shock-induced boundary-layer separation have significant effects on the pressure-loading variations and hence the pitching characteristics. At present the methods of predicting these effects are either nonexistent or oversimplified. The downwash from the forward panel is also difficult to evaluate for cases of mixed flow and/or separation over the forward panel.

DATCOM METHOD

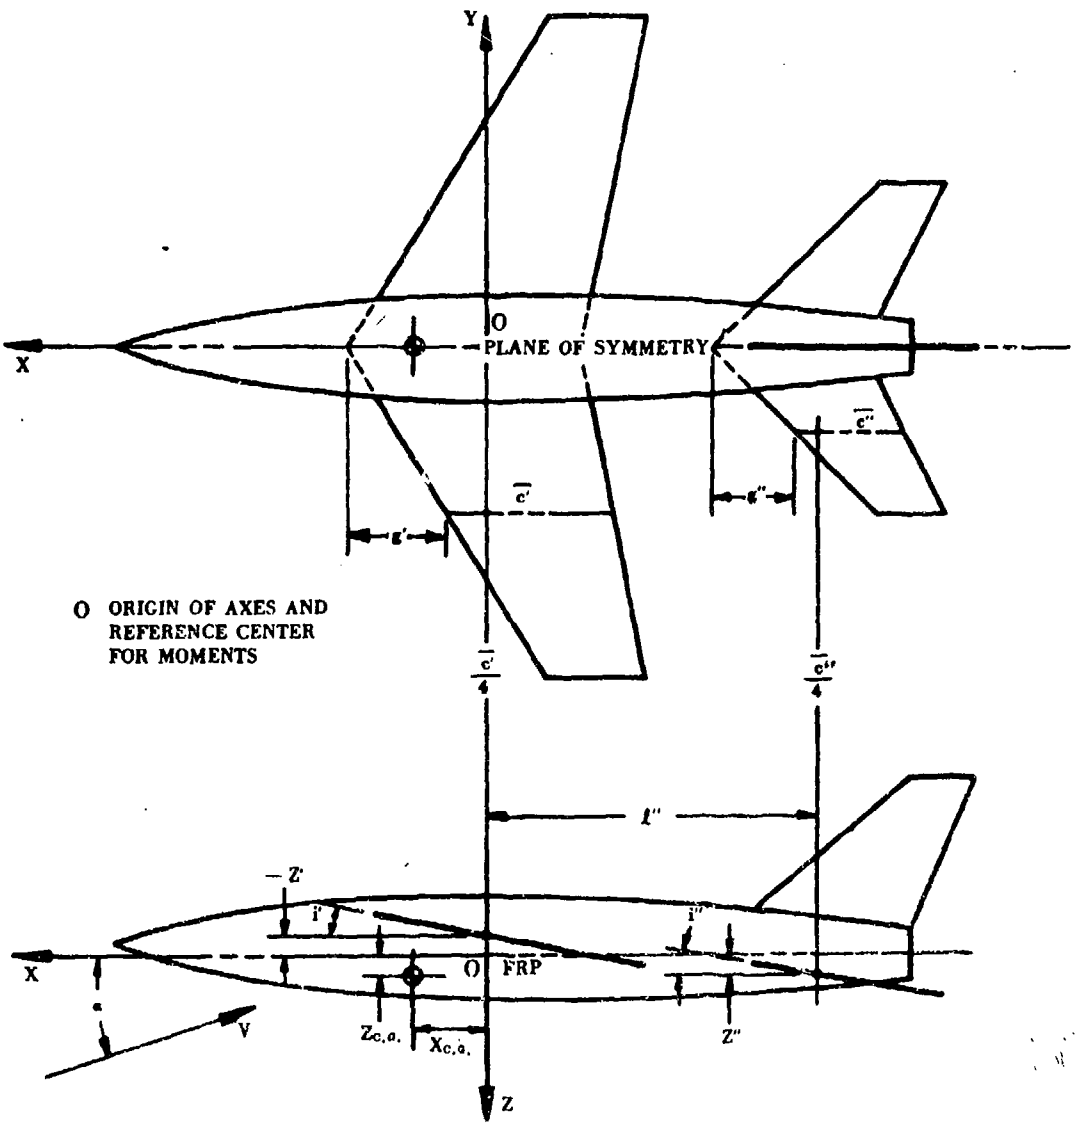
It is recommended that the procedure outlined in paragraph A above be applied at transonic speeds.

C. SUPERSONIC

The information included in the Datcom accounts for most of the mutual interferences that occur between components at supersonic speeds. In particular, the wing-body interferences have been accounted for by the slender-body interference factors of Section 4.3.1.2. The wing-wing interference methods include the effects of the downwash field due to lift, the downwash due to the local compressible flow field, Mach number, and the local dynamic pressure.

DATCOM METHOD

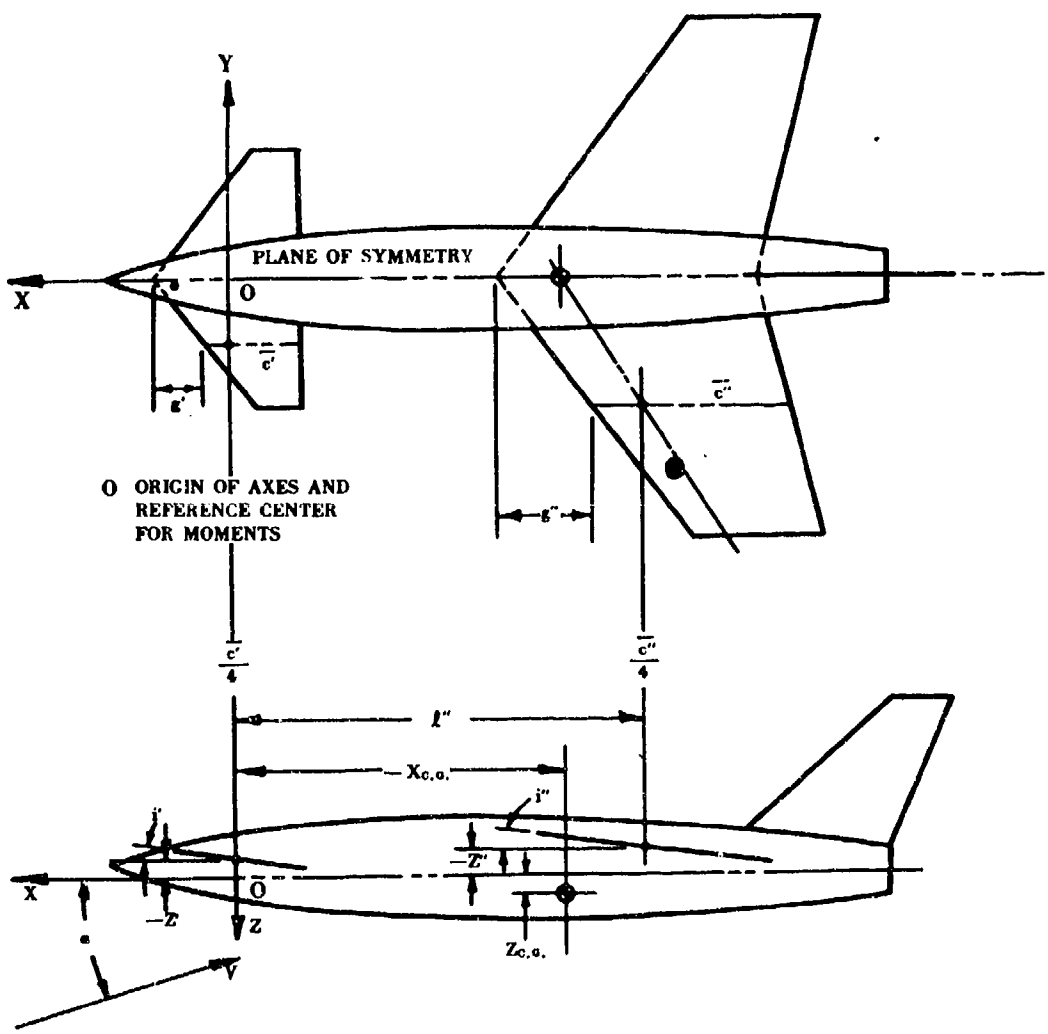
The equations presented in paragraph A for estimating the pitching-moment-curve slope of wing-body-tail combinations are applicable to the supersonic speed regime.



VEHICLE GEOMETRY FOR TAIL-LAST CONFIGURATIONS

Figure 4.5.2.1-7a VEHICLE GEOMETRIC PARAMETERS

Note: Z' and Z'' are measured from the FRP to the aerodynamic centers of the forward and aft surfaces, respectively.



GEOMETRY FOR TAIL-FIRST CONFIGURATIONS

Figure 4.5.2.1-7b VEHICLE GEOMETRIC PARAMETERS (CONTD)

Note: Z' and Z'' are measured from the FRP to the aerodynamic centers of the forward and aft surfaces, respectively.

4.5.3 WING-BODY-TAIL DRAG

4.5.3.1 WING-BODY-TAIL ZERO-LIFT DRAG

The information presented in this section is for estimating the zero-lift drag coefficient of complete configurations in the aerodynamically clean condition. In general it consists of a synthesis of material presented in other sections. The methods are presented for a tail-aft configuration. The procedures to be applied in treating canard configurations in the various speed regimes are noted.

The problem of estimating the zero-lift drag is one of accounting for the mutual interferences between components. The methods use basically the same approaches to account for mutual interferences at subsonic and supersonic speeds as those of paragraphs A and C, respectively, of Section 4.3.3.1 for determining wing-body zero-lift drag. The Datcom method at subsonic speeds consists of applying an interference correction factor to the skin-friction and pressure-drag contributions of the exposed wing and body, and treating the tail panels as exposed components. At supersonic speeds the zero-lift drag of the configuration is obtained by adding the drag contributions of the exposed lifting surfaces and the isolated body. A simple fairing technique is used to approximate the zero-lift drag rise through the transonic speed regime.

Discussions of the various applicable theories are given in Sections 4.1.5.1, 4.2.3.1, and 4.3.3.1 and are not repeated here.

It should be pointed out that the basic approach taken here is satisfactory for preliminary design stability studies and that no attempt is made to provide methods suitable for performance estimates.

A. SUBSONIC ($M \leq 0.70$)

The zero-lift drag of a wing-body-tail configuration is approximated by adding the wing-body zero-lift drag determined by the method of Section 4.3.3.1 and the drag contributions of the isolated tail panels determined by the method of Section 4.1.5.1. Although the method for determining the wing-body contribution includes interference correction factors based on experimental results for wing-body combinations, it should be pointed out that most of the bodies were conventional, ogive-cylinder combinations of high fineness ratio, and no detailed investigation has been made to evaluate body effects. The tail-body combination also produces interference drag, but no explicit correction factors are presented for this effect. Chapter VII of reference 1 discusses the interference drag produced by tail configurations at their junctions with the fuselage as well as in the corners formed by the intersection of horizontal and vertical tails. Tail-body interference is compensated for to some extent in the Datcom by assuming that the average dynamic-pressure ratio at the tail panels is unity.

The Datcom method is applicable to configurations employing the following two classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal planforms)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

Non-straight-tapered wing geometric parameters are presented in Section 2.2.2.

DATCOM METHOD

The subsonic zero-lift drag coefficient of a complete configuration is approximated by

$$C_{D_0} = \left(C_{D_0}\right)_{WB} + \Sigma_p \left(C_{D_0}\right)_p \qquad 4.5.3.1\text{-a}$$

where the subscript p refers to the tail panels, and

$\left(C_{D_0}\right)_{WB}$ is the zero-lift drag coefficient of the wing-body configuration, based on the reference area, obtained from paragraph A of Section 4.3.3.1.

$\left(C_{D_0}\right)_p$ is the zero-lift drag coefficient of a tail panel, based on the exposed panel geometry and referred to the reference area, obtained from paragraph A of Section 4.1.5.1. Applied in this manner, equation 4.1.5.1-a is expressed as

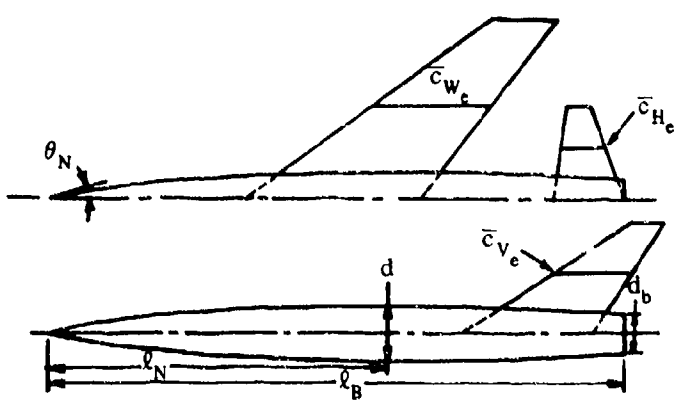
$$\left(C_{D_0}\right)_p = (C_f)_p \left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_p (R_{L.S.})_p \frac{\left[(S_{wet})_p\right]_e}{S_{ref}}$$

where $\left[(S_{wet})_p\right]_e$ is the wetted area of the exposed panel. The Reynolds number used in determining the turbulent flat-plate skin-friction coefficient is based on the mean aerodynamic chord $(\bar{c}_p)_e$ of the exposed panel.

The method is applied to tail-forward configurations by applying the wing-body method of Section 4.3.3.1 to the primary lifting-surface-body combination and the method of Section 4.1.5.1 to the exposed forward panel.

Sample Problem

Given: A wing-body-tail configuration of reference 2, designated 53-series.



Wing Characteristics:

$A_W = 3.0$ $b_W = 10.80$ in. $\lambda_W = 0.40$ $S_W = S_{ref} = 38.89$ sq in.

$\Lambda_{LE_W} = 53.13^o$ $(\bar{c}_W)_e = 3.55$ in. $\left[(S_{wet})_W\right]_e = 62.86$ sq in.

$(t/c)_{av} = 0.044$ $(t/c)_{max}$ @ 0.30c $\Lambda_{(t/c)_{max}} = 49.3^o$

$$\frac{\left[(S_{wet})_W\right]_e}{S_{ref}} = 1.616$$

Horizontal-Tail Characteristics:

$A_H = 3.994$ $b_H = 5.56$ in. $\lambda_H = 0.334$ $\Lambda_{LE_H} = 8.53^o$

$(\bar{c}_H)_e = 1.296$ in. $\left[(S_{wet})_H\right]_e = 10.372$ sq in. $t/c = 0.03$

$(t/c)_{max}$ @ 0.30c $\Lambda_{(t/c)_{max}} = 0$ $\dfrac{\left[(S_{wet})_H\right]_e}{S_{ref}} = 0.2667$

Vertical-Tail Characteristics:

$A_V = 1.356$ $b_V = 3.294$ in. $\lambda_V = 0.275$ $\Lambda_{LE_V} = 56.55^o$

$(\bar{c}_V)_e = 2.305$ in. $\left[(S_{wet})_V\right]_e = 11.01$ sq in. $t/c = 0.03$

$(t/c)_{max}$ @ 0.30c $\Lambda_{(t/c)_{max}} = 45.3^o$ $\dfrac{\left[(S_{wet})_V\right]_e}{S_{ref}} = 0.2832$

Body Characteristics:

$\ell_B = 17.0$ in. $d = d_{max} = 1.588$ in. $d_b = 1.174$ in. $S_B = 1.083$ sq in.

$f = \ell_B/d = 10.70$ $d_b/d = 0.739$ $(S_S)_e = 23.63$ sq in. $\dfrac{(S_S)_e}{S_B} = 21.82$

$\dfrac{(S_S)_e}{S_{ref}} = 0.6076$ $\dfrac{S_B}{S_{ref}} = 0.0278$ Body ordinates: $r = 0.794\left[1 - \left(1 - \dfrac{2x}{19.833}\right)^2\right]^{3/4}$

The body is modified by a 1.369-inch cylindrical extension at $x = 12$.

Additional Characteristics:

$R_\ell = 0.393 \times 10^6$ per in. Polished metal surfaces (assume k = 0)

M = 0.4, 0.6, 0.7

Compute:

Step 1. Determine C_f for each component (Section 4.1.5.1) (For all components the admissible roughness $\ell/k = \infty$, and the skin-friction coefficient is obtained at the calculated R_ℓ)

Reynolds numbers

Wing: $R_\ell = (0.393 \times 10^6)(\bar{c}_W)_e = (0.393 \times 10^6)(3.55) = 1.395 \times 10^6$

Horizontal: $R_\ell = (0.393 \times 10^6)(\bar{c}_H)_e = (0.393 \times 10^6)(1.296) = 5.09 \times 10^5$

Vertical: $R_\ell = (0.393 \times 10^6)(\bar{c}_V)_e = (0.393 \times 10^6)(2.305) = 9.06 \times 10^5$

Body: $R_\ell = (0.393 \times 10^6)(\ell_B) = (0.393 \times 10^6)(17.0) = 6.68 \times 10^6$

Skin-friction coefficients as f(M) (figure 4.1.5.1-26)

M	$(C_f)_W$	$(C_f)_H$	$(C_f)_V$	$(C_f)_B$
0.4	0.00413	0.00495	0.00444	0.00315
0.6	0.00407	0.00488	0.00440	0.00310
0.7	0.00404	0.00484	0.00436	0.00308

Step 2. Determine the skin-friction and pressure-drag contributions of the components. (Sections 4.1.5.1 and 4.2.3.1)

Wing: $\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_W = 1.05$ (figure 4.1.5.1-26a, for L = 1.2)

Horizontal: $\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_H = 1.02$ (figure 4.1.5.1-26a, for L = 1.2)

Vertical: $\left[1 + L\left(\frac{t}{c}\right) + 100\left(\frac{t}{c}\right)^4\right]_V = 1.02$ (figure 4.1.5.1-26a, for L = 1.2)

Body: $$\left[1 + \frac{60}{(\ell_B/d)^3} + 0.0025\,\frac{\ell_B}{d}\right] = \left[1 + \frac{60}{(10.7)^3} + 0.0025\,(10.7)\right] = 1.0757$$

Step 3. Determine the lifting-surface correction factors. (Section 4.1.5.1)

Wing: $\cos \Lambda_{(t/c)_{max}} = 49.3^{o} = 0.6521$

Horizontal: $\cos \Lambda_{(t/c)_{max}} = \cos(0) = 1.00$

Vertical: $\cos \Lambda_{(t/c)_{max}} = \cos 45.3^{o} = 0.7034$

Lifting-surface correction factors as f(M) (figure 4.1.5.1-28b)

M	$(R_{L.S.})_W$	$(R_{L.S.})_H$	$(R_{L.S.})_V$

The calculated results are compared with test values from reference 2 in figure 4.5.3.1-18.

B. TRANSONIC ($0.7 \leq M \leq 1.1$)

Interference effects in the transonic range are generally greater than those in the subsonic range. This is due to the higher local velocities over the individual components and the greater propagation of the associated perturbations from their source. Furthermore, large supersonic flow regions often exist that contribute substantially to the wave drag. These effects may be accounted for by the application of the area-rule method, whereby the zero-lift drag of a wing-body-tail combination can be calculated as though the combination were a body of revolution with equivalent-area cross sections.

Application of the area-rule method for computation of transonic zero-lift drag is discussed in paragraph B of Section 4.3.3.1 and will not be repeated here. Since the method is quite tedious to compute by hand, automatic computing equipment is invariably used.

There is no general method available for determining the interference drag between components at transonic speeds. The method of approach used in Section 4.3.3.1 to determine transonic wing-body zero-lift drag could be extended to include the contributions of the tail panels in a manner similar to that used in paragraph A. However, such a method is considered to be unwarranted in view of the approximate nature of the results in conjunction with the labor required to apply the method.

The Datcom method has been selected for its ease of application. The degree of accuracy of the Datcom method should be equivalent to that using the build-up procedure discussed above.

DATCOM METHOD

An indication of the wing-body-tail zero-lift drag coefficient at transonic speeds may be obtained by the following procedure:

Step 1. Calculate the zero-lift drag coefficient over the subsonic and supersonic speed regimes by the methods of paragraphs A and C, respectively.

Step 2. Obtain the drag-divergence Mach number M_D from figure 4.5.3.1-19 as a function of wing geometry and general wing-body configuration.

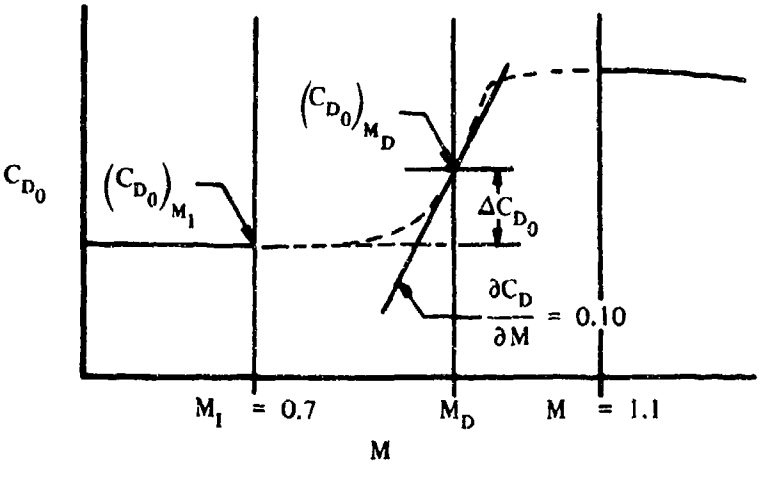
Step 3. Obtain the zero-lift drag coefficient at M_D by

$$\left(C_{D_0}\right)_{M_D} = \left(C_{D_0}\right)_{M=0.7} + 0.002 \qquad 4.5.3.1\text{-b}$$

Step 4. Using the information determined in steps 1 through 3 as a guide, construct the approximate zero-lift drag coefficient for the range of Mach numbers between 0.7 and 1.1. The C_{D_0} vs M curve is faired tangent to a line whose slope is $\partial C_D/\partial M = 0.10$ passing through $\left(C_{D_0}\right)_{M_D}$

Equation 4.5.3.1-b for determining $\left(C_{D_0}\right)_{M_D}$ is arbitrary, since for all configurations an initial drag rise at $M_I = 0.7$ is assumed, and the drag-rise increment $\Delta C_{D_0} = \left[\left(C_{D_0}\right)_{M_D} - \left(C_{D_0}\right)_{M_I}\right]$ is assumed to be 0.002. (See sketch (a)).

The method is applicable only to tail-aft configurations with straight-tapered wings.



SKETCH (a)

Sample Problem

Given: The configuration of the sample problem of paragraph A. Some of the characteristics are repeated.

$A_W = 3.0 \quad \lambda_W = 0.40 \quad (\Lambda_{c/4})_W = 49.8^\circ$

$(t/c)_{av}$ = 0.044 Swept wing design without area rule

Compute:

M_D = 0.96 (figure 4.5.3.1-19)

$\left(C_{D_0}\right)_{M=0.7}$ = 0.0131 (sample problem, paragraph A)

$\left(C_{D_0}\right)_{M_D} = \left(C_{D_0}\right)_{M=0.7} + 0.002$ (equation 4.5.3.1-b)

$= 0.0131 + 0.002$

$= 0.0151$

The zero-lift drag coefficient is constructed for the range of Mach numbers between 0.7 and 1.1 in figure 4.5.3.1-18.

C. SUPERSONIC ($M \geq 1.1$)

The area-rule method, discussed in paragraph B of Section 4.3.3.1, has been adapted to supersonic speeds to allow the computation of the zero-lift drag of complete configurations at supersonic speeds. The resulting method, termed the "supersonic area rule" gives wave drag, including aerodynamic interferences, at a given Mach number.

Application of the "supersonic area rule" requires automatic computing equipment. A general discussion of the method and the steps required to prepare the machine input and to interpret the computed drag values are given in paragraph C of Section 4.3.3.1.

The method presented is essentially the same as that of paragraph A of this section. The zero-lift drag of exposed tail panels determined by the method of Section 4.1.5.1 is added to the wing-body zero-lift drag determined by the method of Section 4.3.3.1.

The Datcom method may be applied to configurations having the following classes of wing planforms:

Straight-Tapered Wings (conventional, trapezoidal planforms)

Non-Straight-Tapered Wings

- Double-delta wings
- Cranked wings
- Curved (Gothic and ogee) wings

Non-straight-tapered wing geometric parameters are presented in Section 2.2.2.

It is assumed that the average dynamic-pressure ratio at the tail panels is unity.

DATCOM METHOD

The supersonic zero-lift drag coefficient of a complete configuration is approximated by equation 4.5.3.1-a; i.e.,

$$C_{D_0} = \left(C_{D_0}\right)_{WB} + \Sigma_p \left(C_{D_0}\right)_p$$

where the subscript p refers to the tail panels, and

$\left(C_{D_0}\right)_{WB}$ is the zero-lift drag of the wing-body configuration, based on the reference area, obtained from paragraph C of Section 4.3.3.1.

$\left(C_{D_0}\right)_p$ is the zero-lift drag coefficient of a tail panel, based on the exposed panel geometry and referred to the reference area, obtained from paragraph C of Section 4.1.5.1. In applying this method the Reynolds numbers used in determining the turbulent flat-plate skin-friction coefficients are based on the mean aerodynamic chord $(\bar{c}_p)_e$ of the exposed panels, and the wetted areas are the exposed wetted areas of the panels $\left[(S_{wet})_p\right]_e$.

The method is applied to tail-forward configurations in the same manner as noted at the conclusion of paragraph A.

Sample Problem

Given: The configuration of the sample problem of paragraph A. Some of the characteristics are repeated.

Wing Characteristics:

$S_W = S_{ref} = 38.89$ sq in. $\quad (S_W)_e = 31.43$ sq in.

$\Lambda_{LE} = 53.13^o \quad (\bar{c}_W)_e = 3.55$ in. $\quad \left[(S_{wet})_W\right]_e = 62.86$ sq in.

$(t/c)_{av} = (t/c)_{eff} = 0.044 \quad \dfrac{(S_W)_e}{S_{ref}} = 0.808 \quad \dfrac{\left[(S_{wet})_W\right]_e}{S_{ref}} = 1.616$

Horizontal-Tail Characteristics:

$(S_H)_e = 5.186$ sq in. $\quad \left[(S_{wet})_H\right]_e = 10.372$ sq in.

$\Lambda_{LE_H} = 8.53^o \quad (\bar{c}_H)_e = 1.296$ in. $\quad t/c = (t/c)_{eff} = 0.03$

$\dfrac{(S_H)_e}{S_{ref}} = 0.1333 \quad \dfrac{\left[(S_{wet})_H\right]_e}{S_{ref}} = 0.2667$

Vertical-Tail Characteristics:

$(S_V)_e = 5.507$ sq in. $\quad \left[(S_{wet})_V\right]_e = 11.014$ sq in.

$\Lambda_{LE_V} = 56.55^o \quad (\bar{c}_V)_e = 2.305$ in. $\quad t/c = (t/c)_{eff} = 0.03$

$\dfrac{(S_V)_e}{S_{ref}} = 0.1416 \quad \dfrac{\left[(S_{wet})_V\right]_e}{S_{ref}} = 0.2832$

Body Characteristics:

$\ell_B = 17.0$ in. $\quad d = d_{max} = 1.588$ in. $\quad d_b = 1.174$ in. $\quad S_B = 1.083$ sq in.

$\ell_A = 7.0$ in. $\quad \ell_N = 10.0$ in. $\quad f_A = \ell_A/d = 4.408 \quad f_N = \ell_N/d = 6.297$

$\theta_N = 17^o \quad (S_S)_e = 23.63$ sq in. $\quad \dfrac{(S_S)_e}{S_{ref}} = 0.6076 \quad \dfrac{S_B}{S_{ref}} = 0.0278$

$\dfrac{(S_S)_e}{S_B} = 21.82$

Additional Characteristics:

$R_\ell \simeq 0.250 \times 10^6$ per in. Polished metal surface (assume $k = 0$)

M	1.10	1.20	1.30	1.40	Biconvex airfoils
β	0.458	0.663	0.831	0.980	

Compute:

Step 1. Determine C_f for each component (Section 4.1.5.1) (For all components the admissible roughness $\ell/k = \infty$, and the skin-friction coefficient is obtained at the calculated R_ℓ.)

Reynolds number

Wing: $R_\ell = (0.250 \times 10^6)(\bar{c}_W)_e = (0.250 \times 10^6)(3.55) = 8.875 \times 10^5$

Horizontal: $R_\ell = (0.250 \times 10^6)(\bar{c}_H)_e = (0.250 \times 10^6)(1.296) = 3.24 \times 10^5$

Vertical: $R_\ell = (0.250 \times 10^6)(\bar{c}_V)_e = (0.250 \times 10^6)(2.305) = 5.76 \times 10^5$

Body: $R_\ell = (0.250 \times 10^6)(\ell_B) = (0.250 \times 10^6)(17.0) = 4.25 \times 10^6$

Skin-friction coefficients (figure 4.1.5.1-26)

1.30	0.00653	0.00131	0.00123
1.40	0.00642	0.00129	0.00121

Step 3. Determine the wave-drag coefficients of the lifting surfaces, based on S_{ref}. (Section 4.3.3.1) (Since all lifting surfaces are conventional, straight-tapered planforms, the subscript bw used in Section 4.3.3.1 has been dropped.)

Wing:

$K = \frac{16}{3}$ (biconvex airfoil. See table, paragraph C, Section 4.1.5.1.)

$\beta \cot \Lambda_{LE_W} < 1.0$ for all M

$$\left(C_{D_w}\right)_W = K \cot \Lambda_{LE_W} \left(\frac{t}{c}\right)^2_{eff} \frac{(S_W)_e}{S_{ref}} \text{ (equation 4.3.3.1-i)}$$

$$= \frac{16}{3} \cot 53.13^o (0.044)^2 (0.808) = 0.00626$$

Horizontal:

$$K = \frac{16}{3} \text{ (biconvex airfoil)}$$

$\beta \cot \Lambda_{LE_H} > 1.0$ for all M

$$\left(C_{D_w}\right)_H = \frac{K}{\beta} \left(\frac{t}{c}\right)^2_{eff} \frac{(S_H)_e}{S_{ref}} \text{ (equation 4.3.3.1-h)}$$

$$= \frac{16}{3\beta} (0.03)^2 (0.1333) = \frac{0.000640}{\beta}$$

M	1.10	1.20	1.30	1.40
β	0.458	0.663	0.831	0.980
$\left(C_{D_w}\right)_H$	0.00140	0.000965	0.000770	0.000653

Vertical:

$$K = \frac{16}{3} \text{ (biconvex airfoil)}$$

$\beta \cot \Lambda_{LE_V} < 1.0$ for all M

$$\left(C_{D_w}\right)_V = K \cot \Lambda_{LE_V} \left(\frac{t}{c}\right)^2_{eff} \frac{(S_V)_e}{S_{ref}} \text{ (equation 4.3.3.1-i)}$$

$$= \frac{16}{3} \cot 56.55^o (0.03)^2 (0.1416) = 0.000449$$

Step 4. Determine the zero-lift drag of the lifting surfaces by combining the results of steps 2 and 3.

$$\left(C_{D_0}\right)_{\substack{\text{lifting} \\ \text{surface}}} = \left(C_{D_f} + C_{D_w}\right)_{\substack{\text{lifting} \\ \text{surface}}} \text{ (based on } S_{ref}\text{) (equation 4.3.3.1-e)}$$

GENERAL CONFIGURATION
4.5.3.1-19

4.5.3.2 WING-BODY-TAIL DRAG AT ANGLE OF ATTACK

The information contained in this section is for estimating the drag coefficient of complete vehicle configurations at angle of attack.

The total vehicle drag at angle of attack consists of the following items:

1. wing-body zero-lift drag
2. wing-body induced drag
3. vertical stabilizer zero-lift drag
4. horizontal-stabilizer zero-lift drag
5. horizontal-stabilizer induced drag

The aerodynamic phenomena associated with, and methods for estimating Items 1-3 are presented in Sections 4.1.5.1, 4.3.3.1, 4.3.3.2, and 4.5.3.1 and are not repeated here.

A vehicle in non-maneuvering flight has the horizontal stabilizer or elevator deflected such that the sum of all moments about the vehicle center of gravity is zero. The pitching moment required to trim arises from the tail-lift and drag vectors and the position of these vectors with respect to the vehicle center of gravity. The method presented in this section is concerned primarily with the estimation of the drag increment resulting from the horizontal-stabilizer contribution required to trim the vehicle ($C_{m_{cg}} = 0$) at usable lift coefficients. A tail-aft configuration is assumed.

The equations pertinent to trim drag presented herein are applicable at all speeds. The method is restricted only by the limitations imposed upon the parameters in other sections of the Datcom. Of course, wing-body test values at the appropriate angle of attack are preferred.

DATCOM METHOD

All Speeds

The drag coefficient of a wing-body-tail configuration at angle of attack is given by

$$C_D = \left(C_{D_0}\right)_{WB} + \left(C_{D_0}\right)_V + \left(C_{D_i}\right)_{WB} + \Delta C_{D_{trim}} \qquad 4.5.3.2\text{-a}$$

where all coefficients are based on total wing area, and

$\left(C_{D_0}\right)_{WB}$ is the wing-body zero-lift drag coefficient obtained from Section 4.3.3.1.

$\left(C_{D_0}\right)_V$ is the vertical-stabilizer zero-lift drag coefficient obtained from Section 4.1.5.1 (see Section 4.5.3.1 for proper treatment of this term).

$\left(C_{D_i}\right)_{WB}$ is the induced drag coefficient of the wing-body combination obtained from Section 4.3.3.2.

$\Delta C_{D_{trim}}$ is the drag-coefficient increment between the drag coefficient of the complete vehicle in pitch equilibrium and the drag coefficient of the wing-body-vertical-tail configuration.

The trim-drag coefficient is given by

$$\Delta C_{D_{trim}} = \left(C_{D_H} \cos \epsilon_H + C_{L_H} \sin \epsilon_H\right) \frac{S_H}{S_W} \frac{q_H}{q_\infty} \qquad 4.5.3.2\text{-b}$$

where

C_{D_H} is the horizontal-stabilizer drag coefficient, based on total horizontal-stabilizer area and taken relative to the local-flow direction at the horizontal stabilizer.

C_{L_H} is the horizontal-stabilizer lift coefficient required to trim, based on total horizontal-stabilizer area and taken relative to the local-flow direction at the horizontal stabilizer.

ϵ_H is the average downwash angle at the horizontal stabilizer, obtained from Section 4.4.1.

S_H/S_W is the ratio of total horizontal-stabilizer area to total wing area.

q_H/q_∞ is the average dynamic-pressure ratio at the horizontal tail, obtained from Section 4.4.1.

The horizontal-stabilizer drag coefficient is given by

$$C_{D_H} = \left(C_{D_0}\right)_H + \left(C_{D_i}\right)_H \qquad 4.5.3.2\text{-c}$$

where

$\left(C_{D_0}\right)_H$ is the horizontal-stabilizer zero-lift drag coefficient obtained from Section 4.1.5.1 (see Section 4.5.3.1 for proper treatment of this term).

$\left(C_{D_i}\right)_H$ is the horizontal-stabilizer induced-drag coefficient given by

$$\left(C_{D_i}\right)_H = \frac{\left(C_{L_H}\right)^2}{\pi A_H e_H} \qquad 4.5.3.2\text{-d}$$

where

A_H is the geometric aspect ratio of the horizontal stabilizer.

e_H is Oswald's efficiency factor for induced drag of the horizontal tail. No method presently exists for determining this parameter. For purposes of the Datcom $e_H = 0.50$ for a horizontal stabilizer mounted on a body, and 0.70 for a horizontal stabilizer mounted on the vertical stabilizer.

The horizontal-stabilizer lift coefficient required to trim is given by

$$C_{L_H} = \frac{2\left[\dfrac{C_{m_{WB}}}{\cos(\Omega - \alpha + \epsilon_H)\ \dfrac{S_H}{S_W}\ \dfrac{q_H}{q_\infty}\ \dfrac{x_H}{\bar{c}_W}} + C_{D_{0_H}} \tan(\Omega - \alpha + \epsilon_H)\right]}{1 + \sqrt{1 - 4\left[\dfrac{\tan(\Omega - \alpha + \epsilon_H)}{\pi A_H e_H}\right]\left[\dfrac{C_{m_{WB}}}{\cos(\Omega - \alpha + \epsilon_H)\ \dfrac{S_H}{S_W}\ \dfrac{q_H}{q_\infty}\ \dfrac{x_H}{\bar{c}_W}} + C_{D_{0_H}} \tan(\Omega - \alpha + \epsilon_H)\right]}}$$

4.5.3.2-e

where

$(C_m)_{WB}$ is the wing-body pitching-moment coefficient given by

$$(C_m)_{WB} = (C_L)_{WB}\left(\frac{dC_m}{dC_L}\right)_{WB} + (C_{m_0})_{WB} \qquad 4.5.3.2\text{-f}$$

where

$\left(\dfrac{dC_m}{dC_L}\right)_{WB}$ is the wing-body pitching-moment-curve slope obtained from Section 4.3.2.2.

$(C_{m_0})_{WB}$ is the wing-body zero-lift pitching-moment coefficient. This parameter must be obtained from test data on a similar configuration or from Section 4.3.2.1.

$(C_L)_{WB}$ is the wing-body lift coefficient given by

$$(C_L)_{WB} = (C_{L_\alpha})_{WB}(\alpha - \alpha_0)_{WB} \qquad 4.5.3.2\text{-g}$$

where

$(C_{L_\alpha})_{WB}$ is the wing-body lift-curve slope, obtained from Section 4.3.1.2.

$(\alpha_0)_{WB}$ is the wing-body zero-lift angle of attack obtained from the wing-alone data of Section 4.1.3.1*.

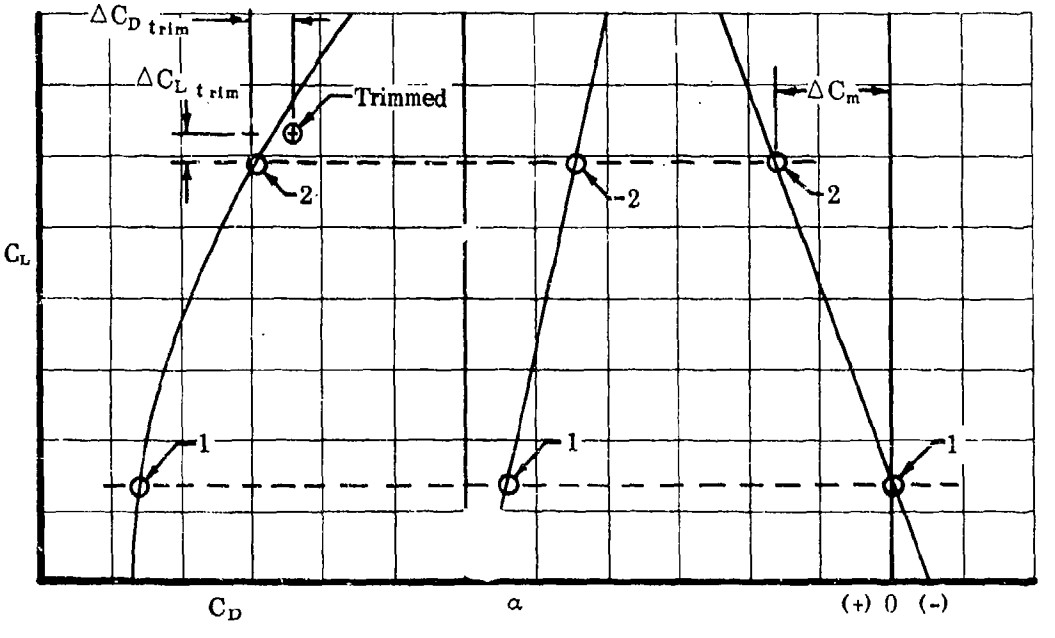
α_{WB} is the wing-body angle of attack.

*Test data from a similar configuration should be used if available. Wing surface velocity is increased by the presence of the fuselage; therefore, when the fuselage is below the wing the lift is reduced and with the fuselage above the wing the lift will be increased. This effect is generally small unless wing-mounted bodies such as stores or nacelles are close to the fuselage or to each other.

x_H is the distance between the vehicle center of gravity and the quarter-chord point of the horizontal-stabilizer MAC (see Figure 4.5.3.2-4).

Ω is the angle defined by the intersection of x_H with the FRP (see Figure 4.5.3.2-4).

The drag increment due to longitudinally trimming a vehicle is used in conjunction with the lift increment required for trim to obtain points on the trimmed drag polar. The procedure used to obtain points on the trimmed drag polar is illustrated in Sketch (a).



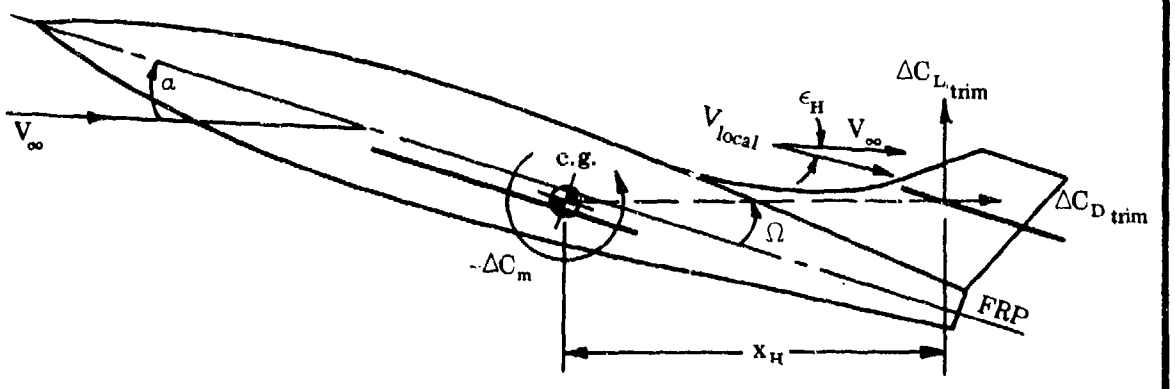
SKETCH (a)

Point 1 represents the horizontal tail-off trimmed condition ($C_{m_{WB}} = 0$). To trim the vehicle at Point 2 the drag polar is corrected for the horizontal-tail load required to apply ΔC_m. This tail load is (see Figure 4.5.3.2-5)

$$-\Delta C_m = -\Delta C_{D_{trim}} \frac{x_H}{\bar{c}_W} \sin(\Omega - \alpha) + \Delta C_{L_{trim}} \frac{x_H}{\bar{c}_W} \cos(\Omega - \alpha)$$

where the lift increment required to trim is

$$\Delta C_{L_{trim}} = \left(C_{L_H} \cos \epsilon_H - C_{D_H} \sin \epsilon_H\right) \frac{S_H}{S_W} \frac{q_H}{q_\infty}$$



VIEW IN PLANE OF SYMMETRY

α = Airplane angle of attack (positive as shown)

x_H = Distance from c.g. to quarter-chord point of horizontal-stabilizer MAC

Ω = Angle defined by intersection of x_H with FRP (positive as shown with horizontal stabilizer above c.g.)

FIGURE 4.5.3.2-5 DEFINITION SKETCH FOR TRIM DRAG CALCULATIONS

4.6 POWER EFFECTS AT ANGLE OF ATTACK

The propulsion unit has many important influences upon the aerodynamic parameters of a vehicle, other than its main function of overcoming drag. The stability and control characteristics in particular can often be affected significantly by the effects of power.

This section presents methods for analyzing the power effects of jet- and propeller-propulsion units. In order to apply the Datcom methods, it is necessary to have experimental results for or to be able to estimate power-off lift and drag-force characteristics of the wing.

The power effects arising from propeller operation are frequently large enough to warrant consideration in preliminary analysis, especially in take-off and landing configurations. The propeller wash usually interacts with the flow around several of the airplane components, creating numerous separate effects that must be evaluated.

Propeller and propeller-wash characteristics are dependent upon several factors, such as blade shapes, fin effects, flow entrainment, and propeller rotating properties (dual rotating, counter rotating, etc.). These factors have prevented the formulation of a complete and accurate theoretical analysis. Consequently, propeller and propeller-wash effects are usually estimated by empirical methods.

The majority of the experimental data used to formulate the methods and design charts for propeller effects in this section were based on single-engine flaps-up configurations, because of a scarcity of adequate flaps-down data on single- or multiple-engine configurations. Consequently, the accuracy of the method for evaluating the power effects for flaps-down configurations is unknown. Methods are presented in Section 9.2 for evaluating the power effects of V/STOL-type aircraft configurations. For flaps-down configurations the methods of Section 9.2 should be used, since they will probably give a more accurate evaluation of the propeller power effects.

Although many of the power effects arising from propellers are undesirable, i.e., destabilizing, some are advantageous. For instance, large increases in maximum lift can be obtained from wing sections immersed in the propeller slipstream with the propeller operating at high-power conditions.

The power effects from jet-propelled aircraft are generally easy to analyze and have relatively minor effects on the stability and control characteristics of a vehicle. The increased simplicity is due to the elimination of the propeller and of the complex flow region of its slipstream on the wing, tail, and other surfaces. Jet-propelled aircraft are designed to keep the jet exhaust at a safe distance from the horizontal tail because of its extreme heat. Therefore, slipstream problems are minimized.

The Datcom methods presented in the following sections estimate the propeller effects at subsonic speeds and the jet effects at subsonic and supersonic speeds on the lift, drag, and pitching moments of a vehicle. By using the methods presented, a variety of vehicle and

power-plant configurations can be evaluated. These include conventional tail-aft aircraft and canard aircraft, having tractor, pusher, and single- and multiple-power plants. Positive- and negative-thrust and windmilling conditions for propellers are included. Reverse-thrust conditions that cause large interferences and flow separation cannot be evaluated by the methods presented in the following sections.

A general notation list and reference list are included in this section for all power-effects sections. Figures 4.6-12 and 4.6-13 indicate the geometric data required by the methods of these sections. Figure 4.6-12 specifically illustrates the geometric data required for calculating the wing area immersed in the slipstream.

NOTATION

SYMBOL	DEFINITION
A	aspect ratio
A_H	aspect ratio of horizontal tail
A_I	engine inlet duct area
A_i	effective aspect ratio of the immersed wing
a	inflow factor
b_H	span of horizontal tail, ft
b_i	span of immersed wing, ft
b_p	blade width, ft
C_1, C_2	constants for determining downwash
C_D	drag coefficient
C_{D_b}	base drag coefficient
C_{D_L}	drag-coefficient due to lift
C_{D_0}	zero-lift drag coefficient

SYMBOL	DEFINITION
ΔC_{D_0}	increment in zero-lift drag coefficient
$\left(\Delta C_{D_0}\right)_s$	increment in skin-friction drag caused by change in dynamic pressure
C_f	local skin-friction drag coefficient
C_L	lift coefficient
C_{L_P}	propeller lift coefficient
C_{L_W}	wing lift coefficient
$\left(\Delta C_L\right)_H$	change in lift coefficient due to horizontal tail
$\Delta C_{L_{max}}$	increment of maximum lift due to power effects
$\left(\Delta C_L\right)_{N_j}$	increment in lift due to the turning of the free-stream flow at the engine inlet
$\left(\Delta C_l\right)_{N_p}$	increment in lift due to propeller normal force
$\left(\Delta C_L\right)_q$	change in lift coefficient due to the change in slipstream dynamic pressure
$\left(\Delta C_L\right)_T$	increment in lift due to thrust
C_{L_α}	lift-curve slope of the power-off lift curve
$C_{L_{\alpha_H}}$	lift-curve slope of the horizontal tail
$\left(\Delta C_L\right)_{\Delta\alpha_w}$	increment in lift due to the upwash or downwash of the propeller flow field
$\left(\Delta C_L\right)_e$	increment in lift due to jet interference effects
C_m	pitching-moment coefficient

SYMBOL	DEFINITION
$\left(C_{m_0}\right)_i$	zero-lift pitching-moment coefficient of the components immersed in the slipstream
$\left(C_{m_0}\right)_{\text{area not immersed}}$	zero-lift pitching-moment coefficient of the area not immersed in the slipstream
$\left(C_{m_0}\right)_{\text{wing-body}}$	zero-lift pitching-moment coefficient of the wing-body combination
$\left(\Delta C_m\right)_H$	total change in pitching-moment coefficient of the horizontal tail
$\left(\Delta C_m\right)_L$	increment in pitching-moment coefficient due to the immersed-wing lift increments
$\left(\Delta C_m\right)_{N_p}$	increment in pitching-moment coefficient due to propeller normal force
$\left(\Delta C_m\right)_q$	increment in pitching-moment coefficient due to the change in slipstream dynamic pressure
$\left(\Delta C_m\right)_T$	increment in pitching-moment coefficient due to the offset of the thrust axis from the origin of the axes
$\left(\Delta C_{m_H}\right)_q$	increment in pitching-moment coefficient due to a change in the dynamic pressure on the horizontal tail
$\left(\Delta C_{m_H}\right)_\epsilon$	increment in pitching-moment coefficient due to a change in the downwash at the horizontal tail
C_{N_p}	propeller normal-force coefficient
$\left(C_{N_\alpha}\right)_p$	propeller normal-force derivative
$\left[\left(C_{N_\alpha}\right)_p\right]_{K_N=80.7}$	propeller normal-force derivative based on $K_N = 80.7$
c_i	average chord of immersed wing section
$\bar{c}$	mean aerodynamic chord, MAC

SYMBOL	DEFINITION
$\bar{c}_H$	mean aerodynamic chord of the horizontal tail
$\bar{c}_{\text{area not immersed}}$	mean aerodynamic chord of the wing area not immersed in the slipstream
f	propeller-inflow factor
h	altitude
i_H	incidence of the horizontal tail
i_T	incidence of the thrust axis
i_W	incidence of the wing
K	maximum-lift empirical constant
K_1	nacelle or fuselage empirical constant
K_D	propeller drag factor
K_N	empirical normal-force factor
ℓ_H	distance from axes origin to quarter-chord point on the mean aerodynamic chord of the horizontal tail
M_∞	free-stream Mach number
n	number of engines
n'	load factor
p	pressure
Δp	change in pressure
q	dynamic pressure
Δq	change in dynamic pressure

SYMBOL	DEFINITION
R_j	radius of jet orifice
R'_j	radius of equivalent jet orifice
R_p	propeller radius
S	reference area
S_{H_i}	area of portion of horizontal tail immersed in propeller slipstream
S_I	total surface area immersed in the slipstream
S_p	propeller disk area
S_W	wing area
S_{W_f}	wing planform area including and directly forward of flap area
T	thrust per engine
T'_c	thrust coefficient per engine
V	velocity
V_j	actual jet velocity
V'_j	equivalent jet velocity
W	weight
x'_e	longitudinal distance from the jet exit to the quarter-chord point of horizontal-tail mean aerodynamic chord
x'_H	longitudinal distance from jet-wake origin to quarter-chord point of horizontal-tail mean aerodynamic chord
x_I	longitudinal distance from quarter-chord point of wing mean aerodynamic chord to leading edge of engine inlet
x'_j	longitudinal distance from jet-wake origin to jet exit, usually considered to be 4.6 times the orifice exhaust radius

SYMBOL	DEFINITION
x_p	longitudinal distance from intersection of propeller plane with thrust axis and the quarter-chord point of the wing mean aerodynamic chord
x_W	longitudinal distance from moment-reference-center location to the aerodynamic center of the wing area immersed in the slipstream, positive for the aerodynamic center forward of the moment reference center.
y_T	spanwise distance from thrust axis to fuselage center line
z_H	vertical distance from X-axis to quarter-chord point of horizontal-tail mean aerodynamic chord
$z_{H_{eff}}$	vertical distance from quarter-chord point of horizontal-tail mean aerodynamic chord to the slipstream center line
z_{H_T}	vertical distance from propeller thrust axis to quarter-chord point of horizontal-tail mean aerodynamic chord
z_j'	vertical distance from jet thrust axis to quarter-chord point of horizontal-tail mean aerodynamic chord
z_s	vertical distance from X-axis to propeller-slipstream center line at the quarter-chord point of the wing mean aerodynamic chord
z_T	vertical distance from propeller thrust axis to coordinate origin
z_W	vertical distance from the quarter-chord point of the wing mean aerodynamic chord to the coordinate origin
α	angle of attack
α_0	angle of attack at zero lift
α_j	angle between thrust axis and direction of local velocity
α_p	angle between direction of local airstream and thrust axis
α_T	angle between thrust axis and direction of free stream
α_W	wing angle of attack
$\alpha_{C_{L_{max}}}$	angle of attack at maximum lift

SYMBOL	DEFINITION
β	propeller blade angle at 0.75 radius
ϵ_H	downwash at the quarter-chord point of the horizontal-tail mean aerodynamic chord
ϵ_p	downwash angle behind the propeller
ϵ_u	upwash angle ahead of wing
$\bar{\epsilon}$	effective downwash over the wing span
$\Delta\epsilon$	downwash increment
$\Delta\bar{\epsilon}$	mean-effective-downwash increment
$\frac{\Delta\bar{\epsilon}}{\Delta\epsilon}$	mean-effective-downwash ratio
$\frac{\partial\epsilon_p}{\partial\alpha_p}$	propeller-downwash gradient
$\frac{\partial\epsilon_u}{\partial\alpha}$	upwash gradient
λ_H	taper ratio of the horizontal tail
$\Lambda_{c/4}$	sweep angle of the wing quarter-chord
$\Lambda_{H_{c/4}}$	sweep angle of the horizontal-tail quarter-chord

SUBSCRIPTS

b	base conditions
H	horizontal tail
i	immersed in slipstream
L	lift
N	normal force

SYMBOL	DEFINITION
N_p	propeller normal force
s	slipstream conditions
T	thrust
W	wing
α	angle of attack
∞	free-stream conditions

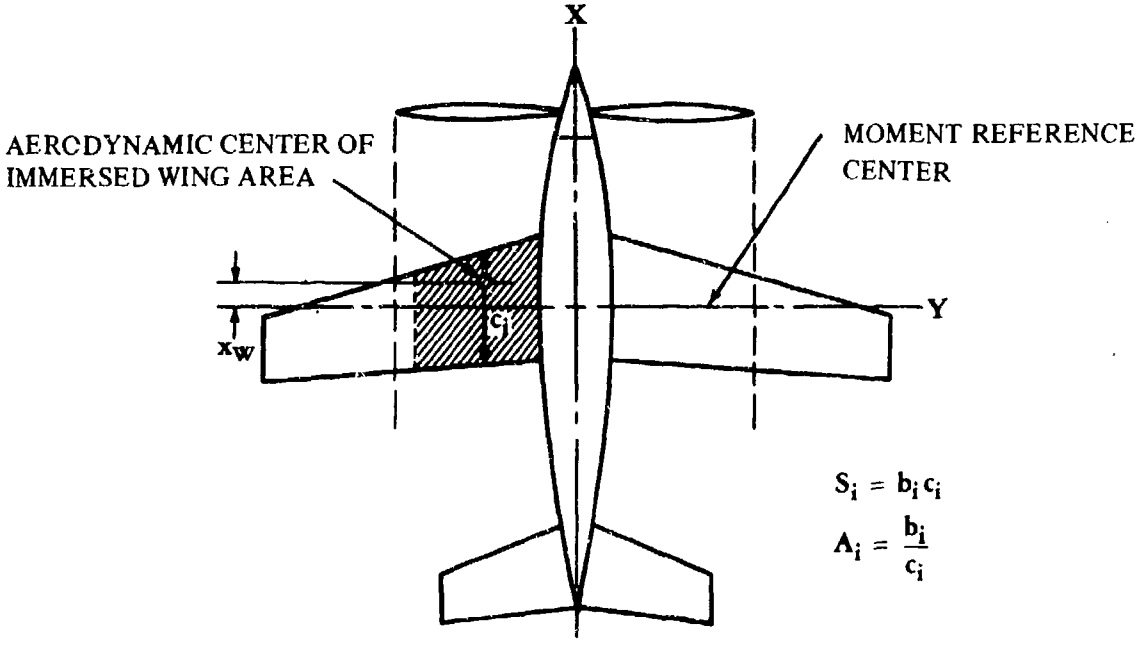
$$b_i = 2\sqrt{R_p^2 - (z_s + z_w)^2}$$

Cross section taken at quarter-chord of wing MAC for S_i (S_{H_i} is found in an identical manner as S_i with the cross section taken at the quarter-chord of the tail MAC.)



$$S_i = b_i c_i$$

$$A_i = \frac{b_i}{c_i}$$

FIGURE 4.6-12 DEFINITION SKETCH FOR CALCULATION OF IMMERSED WING AREA

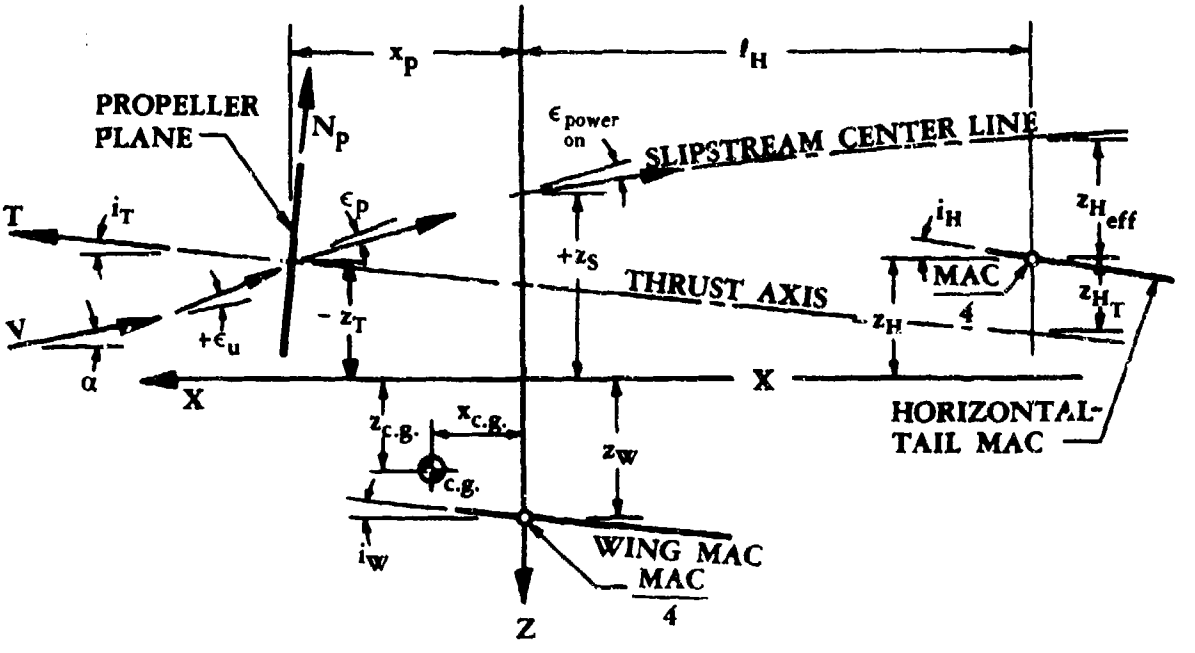


FIGURE 4.6-13a DEFINITION SKETCH FOR PROPELLER POWER EFFECTS CALCULATIONS

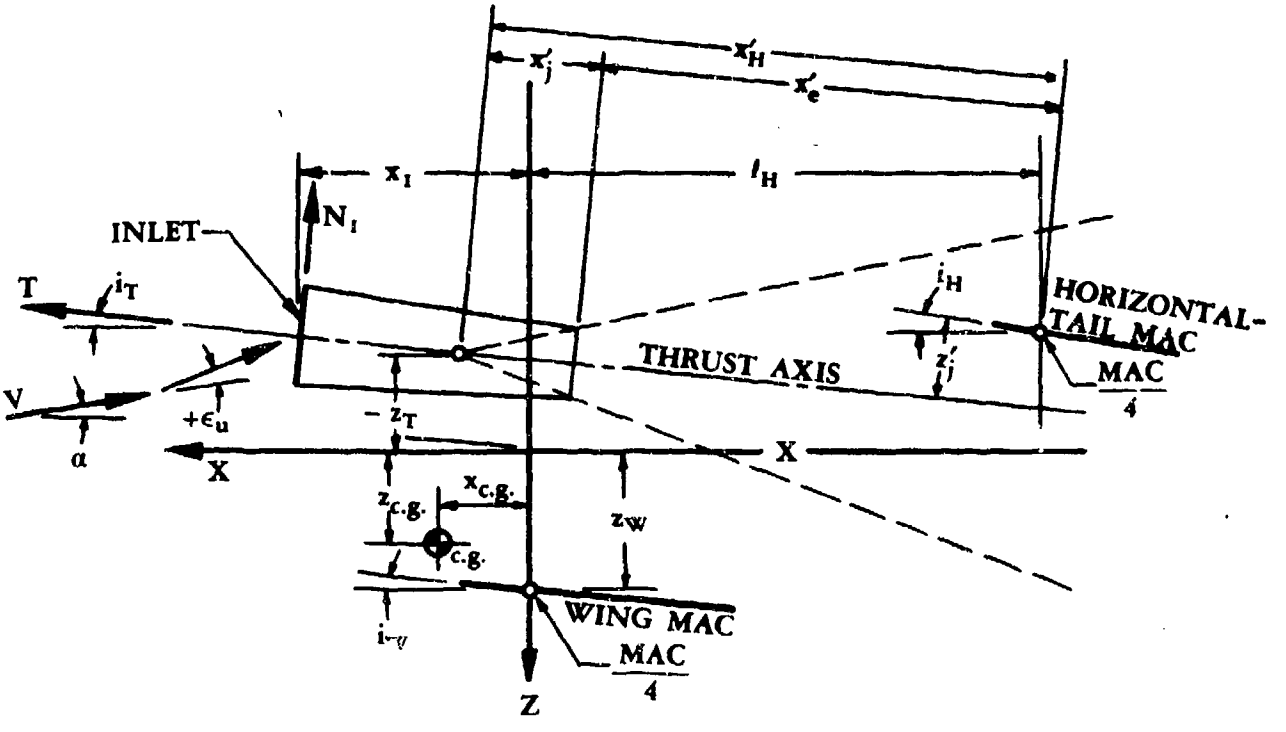

FIGURE 4.6-13b DEFINITION SKETCH FOR JET POWER EFFECTS CALCULATIONS

4.6.1 POWER EFFECTS ON LIFT VARIATION WITH ANGLE OF ATTACK

A. PROPELLER POWER EFFECTS ON LIFT

The primary purpose of a propeller is to develop thrust. In performing this function, the propeller often causes pronounced changes in the aerodynamic characteristics of a vehicle.

The effects of a propeller on the forces and moments acting on a vehicle may be divided into two groups, those due to the direct action of the propeller forces and those due to the propeller slipstream.

The first group includes the forces and moments due to the thrust vector and the forces and moments acting on the propeller as a result of its inclination to the oncoming stream. When a propeller is placed at an angle of attack, a force results normal to the thrust axis in the vertical plane. A pitching moment and a yawing moment also result. These forces and moments act on the propeller because of the unsymmetrical loading on the blades as a function of their rotational position. For counterrotating propellers the normal forces and pitching moments are additive, but the yawing moments cancel. These forces and moments are generally functions of propeller geometry.

The second group, those due to slipstream effects, depends greatly upon the component arrangement of the vehicle. However, the following generalizations can be made.

The dynamic pressure behind the propeller may be greater or less than the free-stream dynamic pressure, depending upon whether the propeller is delivering positive or negative thrust, respectively. The forces and moments acting on airframe components immersed in the slipstream are directly proportional to the slipstream dynamic pressure.

Because of the normal force acting on a propeller at angle of attack, a downwash field is generated behind the propeller plane. This downwash field changes the angle of attack of the airframe components operating in the propeller slipstream.

The method presented in this section for estimating propeller power effects on lift is based on a tail-last configuration. The method was taken from reference 1, which was developed from reference 2. The method predicts increments of lift for given values of thrust coefficient and angle of attack in the linear range. The effect of power on maximum lift is given in Section 4.6.2.

DATCOM METHOD

The Datcom method estimates the power-on lift curves based on power-off lift curves as a function of angle of attack, thrust coefficient, and lift coefficient.

This method analyzes the increments of lift coefficient due to propeller power effects in the following order:

1. Lift component of the thrust
2. Lift component of the propeller normal force
3. Change in angle of attack of the section of the wing in the propeller slipstream, due to the downwash flow field behind the propeller
4. Change in dynamic pressure over the section of the wing in the propeller slipstream
5. Change in lift due to downwash and changes in dynamic pressure acting on the horizontal tail

After the above lift increments for a given angle of attack have been calculated, the accumulated total is then applied to the power-off lift curve to obtain a point on the power-on lift curve. After several points have been generated (by considering several angles of attack), the linear section of the power-on lift curve is obtained for a given thrust coefficient.

The above increments in lift can be determined by the following steps. (Reference should be made to figure 4.6-13a for geometric definitions. In all cases the lift increments are based on the wing reference area.)

Step 1. Calculate the lift component of thrust as follows:

a. Calculate the angle of attack of the thrust axis α_T measured from the free-stream direction by

$$\alpha_T = i_T + \alpha \qquad 4.6.1\text{-a}$$

b. Calculate the thrust coefficient per engine T_c' (if not given or assumed) by

$$T_c' = \frac{T}{q_\infty S_W} \qquad 4.6.1\text{-b}$$

where the thrust per engine T is a given or chosen quantity.

c. Calculate the lift component of thrust by

$$\left(\Delta C_L\right)_T = nT_c' \sin \alpha_T \qquad 4.6.1\text{-c}$$

where n is the number of engines. This equation is valid only when the thrust coefficients and the angles of attack of the thrust axis to the free stream are equal for all n engines.

Step 2. Calculate the lift component of propeller normal force per engine as follows:

a. Calculate the empirical normal-force factor K_N per blade (usually supplied by the propeller manufacturer) by

$$K_N = 262\left(\frac{b_p}{R_p}\right)_{.3R_p} + 262\left(\frac{b_p}{R_p}\right)_{.6R_p} + 135\left(\frac{b_p}{R_p}\right)_{.9R_p} \qquad 4.6.1\text{-d}$$

where the subscript indicates the radial position from the center of the propeller where the blade width b_p is to be evaluated.

b. From figure 4.6.1-25a (taken from reference 3) obtain a value for the propeller normal-force coefficient $\left[\left(C_{N_\alpha}\right)_p\right]_{K_N = 80.7}$, based on $K_N = 80.7$, as a function of propeller blade angle and type of propeller.

c. Calculate the true propeller normal-force coefficient $\left(C_{N_\alpha}\right)_p$ by

$$\left(C_{N_\alpha}\right)_p = \left[\left(C_{N_\alpha}\right)_p\right]_{K_N = 80.7}\left[1 + 0.8\left(\frac{K_N}{80.7} - 1\right)\right] \text{ (per radian)} \qquad 4.6.1\text{-e}$$

d. Evaluate the propeller correlation parameter defined as

$$\frac{S_W T_c'}{8R_p^2}$$

e. From figure 4.6.1-25b (taken from reference 3) obtain a value for the propeller-inflow factor f as a function of the propeller correlation parameter evaluated above (step 2.d).

f. Calculate the propeller disk area S_p by

$$S_p = \pi R_p^2 \qquad 4.6.1\text{-f}$$

g. Calculate the angle of attack of the propeller plane (local airstream to thrust axis) α_p by

$$\alpha_p = \alpha_T + \frac{\partial \epsilon_u}{\partial \alpha}(\alpha_W - \alpha_0) \qquad 4.6.1\text{-g}$$

where the upwash gradient $\partial\epsilon_u/\partial\alpha$ at the propeller may be obtained in Section 4.4.1 and

$$\alpha_W = \alpha + i_W \qquad \text{4.6.1-h}$$

h. Calculate the lift component of the propeller normal force by

$$\left(\Delta C_L\right)_{N_p} = f\left(C_{N_\alpha}\right)_p \frac{\alpha_p}{57.3} \frac{S_p}{S_W} \cos\alpha_T \qquad \text{4.6.1-i}$$

For multiple-engine configurations the total lift component of the propeller normal force is found by summing the single components due to each engine.

Step 3. Calculate the increment of lift due to the change in angle of attack on the wing induced by the propeller flow field per engine as follows:

a. Calculate the upwash gradient $\partial\epsilon_p/\partial\alpha_p$ by

$$\frac{\partial\epsilon_p}{\partial\alpha_p} = C_1 + C_2\left(C_{N_\alpha}\right)_p \qquad \text{4.6.1-j}$$

where the constants C_1 and C_2 are obtained from figure 4.6.1-26 as a function of the propeller correlation parameter. The parameter $\left(C_{N_\alpha}\right)_p$ is obtained from step 2.c.

b. Calculate the downwash ϵ_p behind the propeller by

$$\epsilon_p = \frac{\partial\epsilon_p}{\partial\alpha_p}\alpha_p \qquad \text{4.6.1-k}$$

where the angle of attack of the propeller plane α_p is determined in step 2.g.

c. Calculate the change in the wing angle of attack $\Delta\alpha_W$ ahead of or behind the propeller by

$$\Delta\alpha_W = \frac{-\epsilon_p}{1 + \partial\epsilon_u/\partial\alpha} \qquad \text{4.6.1-l}$$

d. Calculate the angle of upwash ϵ_u at the propeller by

$$\epsilon_u = \frac{\partial\epsilon_u}{\partial\alpha}\left(\alpha_W - \alpha_0\right) \qquad \text{4.6.1-m}$$

e. Calculate the vertical distance from the X-axis to the propeller slipstream center line at the quarter-chord of the wing MAC by

$$z_s = x_p \tan(\alpha_T + \epsilon_u - \epsilon_p) - z_T \qquad 4.6.1\text{-n}$$

It should be noted that this equation is based on the assumption that the upwash and downwash are constant from the propeller to the quarter-chord of the MAC.

f. Calculate the span of the immersed wing b_i by

$$b_i = 2\left[R_p^2 - (z_s + z_w)^2\right]^{1/2} \qquad 4.6.1\text{-o}$$

g. Calculate the immersed wing area S_i by

$$S_i = b_i c_i \qquad 4.6.1\text{-p}$$

h. Calculate the effective aspect ratio A_i of the wing immersed in the slipstream (see figure 4.6-12) by

$$A_i = \frac{b_i}{c_i} \qquad 4.6.1\text{-q}$$

i. From figure 4.6.1-27 obtain a value for the empirical constant K_1 accounting for a nacelle or fuselage as a function of the wing and immersed-wing aspect ratio and the propeller correlation parameter (step 2.d).

j. Calculate the gain or loss in slipstream dynamic pressure $\Delta q_s/q_\infty$ by

$$\frac{\Delta q_s}{q_\infty} = \frac{S_W T_c'}{\pi R_p^2} \text{ (per engine)} \qquad 4.6.1\text{-r}$$

k. Calculate the change in wing lift due to the upwash or downwash of the propeller flow field per engine by

$$\left(\Delta C_L\right)_{\Delta\alpha_W} = \left(1 + \frac{\Delta q_s}{q_\infty}\right) \frac{S_i}{S_W} C_{L_\alpha} \Delta\alpha_W K_1 \qquad 4.6.1\text{-s}$$

where C_{L_α} is the lift-curve slope of the power-off lift curve, obtained by using the method of Section 4.1.3.2.

For multiple-engine configurations, the total lift component due to the change in angle of attack on the wing is found by summing the single components due to each engine.

Step 4. Calculate the increment of lift per engine due to the change in slipstream dynamic pressure on the wing by

$$\left(\Delta C_L\right)_q = K_1 \frac{\Delta q_s}{q_\infty} \frac{S_i}{S_W} \left(C_L\right)_{\substack{\text{power} \\ \text{off}}} \qquad 4.6.1\text{-t}$$

where $\left(C_L\right)_{\substack{\text{power} \\ \text{off}}}$ must be obtained from the power-off lift curve at the given angle of attack. For multiple-engine configurations, the total lift component due to the change in slipstream dynamic pressure acting on the wing is found by summing the single components due to each engine.

Step 5. Calculate the increment of lift on the horizontal tail due to the change in dynamic pressure and angle of attack as follows:

a. Calculate the total change in pitching-moment coefficient of the horizontal tail $\left(\Delta C_m\right)_H$ by

$$\left(\Delta C_m\right)_H = \left(\Delta C_{m_H}\right)_e + \left(\Delta C_{m_H}\right)_q \qquad 4.6.1\text{-u}$$

where $\left(\Delta C_{m_H}\right)_e$ and $\left(\Delta C_{m_H}\right)_q$ are calculated in Section 4.6.3.

b. Calculate the lift due to the horizontal tail by

$$\left(\Delta C_L\right)_H = -\left(\Delta C_m\right)_H \frac{\bar{c}}{\ell_H} \qquad 4.6.1\text{-v}$$

Step 6. Calculate the total change of lift due to the propeller power effects by summing the previously calculated elements as follows:

$$\left(\Delta C_L\right)_{\substack{\text{power} \\ \text{on}}} = \left(\Delta C_L\right)_T + \left(\Delta C_L\right)_{N_p} + \left(\Delta C_L\right)_{\Delta\alpha_W} + \left(\Delta C_L\right)_q + \left(\Delta C_L\right)_H \qquad 4.6.1\text{-w}$$

This equation is computed for a range of angles of attack and thrust coefficients, and the lift curves are constructed. These curves are valid only in the linear-lift range.

Sample Problem

The following example is based on the single-engine test configuration of reference 3. The example is presented for one value of α and one value of T_c'.

Given:

Wing Parameters:

$S_W = 380\ ft^2$ $\quad A = 6.23$ $\quad i_W = 2.0°$ $\quad \bar{c} = 8.17\ ft$

$c_l = 9.17\ ft$ $\quad z_W = 1.4\ ft$ $\quad$ Wing root section: NACA 2416

Wing tip section: NACA 4412 $\quad C_{L_\alpha} = 0.08$ per deg $\quad C_{L_{\substack{power\\off}}} = 0.50$ $\quad$ use test data or Sections 4.1.3.2 and 4.1.3.3

Angles:

$\alpha = 4.0°$ (assumed) $\quad \alpha_0 = -2.8°$ $\quad \partial\epsilon_u/\partial\alpha = 0.13$ (Section 4.4.1)

Propeller Parameters:

Four-bladed propeller $\quad R_p = 6.79\ ft$ $\quad \beta = 18°$ (at $0.75\ R_p$) $\quad K_N = 65.8$

Engine Parameters:

$T_c' = 0.150$ per engine (assumed)

$n = 1$ $\quad i_T = 0$ $\quad z_T = 0$ $\quad x_p = 10.9\ ft$

Horizontal-Tail Parameters:

$S_H = 80\ ft^2$ $\quad \ell_H = 20.4\ ft$ $\quad (\Delta C_{n_H}) = 0.0218$ (Section 4.6.3)

Compute:

Determine the lift component of thrust

$\alpha_T = i_T + \alpha$ (equation 4.6.1-a)

$= 0 + 4 = 4°$

$T_c' = 0.150$ (given)

$$\left(\Delta C_L\right)_T = n\, T_c'\, \sin \alpha_T \qquad \text{(equation 4.6.1-c)}$$

$$= (1)\,(0.15)\,(0.0698) = 0.0105$$

Determine the lift component of propeller normal force

$$K_N = 65.8 \text{ (given)}$$

$$\left[\left(C_{N_\alpha}\right)_p\right]_{K_N = 80.7} = 0.165 \qquad \text{(figure 4.6.1-25a)}$$

$$\left(C_{N_\alpha}\right)_p = \left[\left(C_{N_\alpha}\right)_p\right]_{K_N = 80.7} \left[1 + 0.8\left(\frac{K_N}{80.7} - 1\right)\right] \qquad \text{(equation 4.6.1-e)}$$

$$= 0.165 \left[1 + 0.8\left(\frac{65.8}{80.7} - 1\right)\right]$$

$$= 0.141$$

The propeller correlation parameter is

$$\frac{S_W T_c'}{8R_p^2} = \frac{(380)\,(0.15)}{(8)\,(6.79)^2} = 0.155$$

$$f = 1.1 \qquad \text{(figure 4.6.1-25b)}$$

$$S_p = \pi R_p^2 \qquad \text{(equation 4.6.1-f)}$$

$$= (3.14)\,(6.79)^2 = 144.8 \text{ ft}^2$$

$$\frac{\partial \epsilon_u}{\partial \alpha} = 0.13 \text{ (given)}$$

$$\alpha_W = \alpha + i_W \qquad \text{(equation 4.6.1-h)}$$

$$= 4.0 + 2.0 = 6.0^\circ$$

$$\alpha_p = \alpha_T + \frac{\partial \epsilon_u}{\partial \alpha}\left(\alpha_W - \alpha_0\right) \qquad \text{(equation 4.6.1-g)}$$

$$= 4.0 + 0.13\,(6.0 + 2.8)$$

$$= 5.14^\circ$$

$$\left(\Delta C_L\right)_{N_p} = f\left(C_{N_\alpha}\right)_p \frac{\alpha_p}{57.3} \frac{S_p}{S_W} \cos \alpha_T \quad \text{(equation 4.6.1-i)}$$

$$= (1.1)(0.141)\frac{5.14}{57.3}\frac{144.8}{380}(0.998)$$

$$= 0.00529$$

Determine the increment of lift due to the change in angle of attack on the wing induced by the propeller flow field

$$\frac{\partial \epsilon_p}{\partial \alpha_p} = C_1 + C_2 \left(C_{N_\alpha}\right)_p \quad \text{(equation 4.6.1-j)}$$

$$\left.\begin{aligned} C_1 &= 0.08 \\ C_2 &= 0.25 \end{aligned}\right\} \text{(figure 4.6.1-26)}$$

$$\frac{\partial \epsilon_p}{\partial \alpha_p} = 0.08 + (0.25)(0.141) = 0.115$$

$$\epsilon_p = \frac{\partial \epsilon_p}{\partial \alpha_p} \alpha_p \quad \text{(equation 4.6.1-k)}$$

$$= (0.115)(5.14) = 0.59^\circ$$

$$\Delta \alpha_W = \frac{-\epsilon_p}{1 + \partial \epsilon_u / \partial \alpha} \quad \text{(equation 4.6.1-ℓ)}$$

$$= \frac{-0.59}{1 + 0.13} = -0.522^\circ$$

$$\epsilon_u = \frac{\partial \epsilon_u}{\partial \alpha} (\alpha_W - \alpha_0) \quad \text{(equation 4.6.1-m)}$$

$$= 0.13\,(6.0 + 2.8) = 1.14^\circ$$

$$z_s = x_p \tan(\alpha_T + \epsilon_u - \epsilon_p) - z_T \quad \text{(equation 4.6.1-n)}$$

Using the small-angle approximation,

$$z_s = \frac{x_p}{57.3}(\alpha_T + \epsilon_u - \epsilon_p) + 0$$

$$= \frac{10.9}{57.3}(4.0 + 1.14 - 0.59) = 0.866 \text{ ft}$$

$$b_i = 2\left[R_p^2 - (z_s + z_w)^2\right]^{1/2} \quad \text{(equation 4.6.1-o)}$$

$$= 2\left[(6.79)^2 - (0.866 + 1.4)^2\right]^{1/2}$$

$$= 12.8 \text{ ft}$$

$$S_i = b_i c_i \quad \text{(equation 4.6.1-p)}$$

$$= (12.8)(9.17) = 117.4 \text{ ft}^2$$

$$A_i = \frac{b_i}{c_i} \quad \text{(equation 4.6.1-q)}$$

$$= \frac{12.8}{9.17} = 1.40$$

$$K_1 = 0.96 \quad \text{(figure 4.6.1-27)}$$

$$\frac{\Delta q_s}{q_\infty} = \frac{S_w T_c'}{\pi R_p^2} \quad \text{(equation 4.6.1-r)}$$

$$= \frac{(380)(0.15)}{(3.14)(6.79)^2}$$

$$= 0.394$$

$$\left(\Delta C_L\right)_{\Delta\alpha_w} = \left(1 + \frac{\Delta q_s}{q_\infty}\right)\frac{S_i}{S_w} C_{L_\alpha} \Delta\alpha_w K_1 \quad \text{(equation 4.6.1-s)}$$

$$= (1 + 0.394)\ \frac{117.4}{380}\ (0.08)(-0.522)(0.96)$$

$$= -0.0173$$

Determine the increment of lift due to the change in slipstream dynamic pressure

$$\left(\Delta C_L\right)_q = K_1 \frac{\Delta q_s}{q_\infty} \frac{S_i}{S_W} \left(C_L\right)_{\substack{\text{power} \\ \text{off}}} \qquad \text{(equation 4.6.1-t)}$$

$$= (0.96)\,(0.394)\ \frac{117.4}{380}\ (0.50)$$

$$= 0.0584$$

Determine the increment of lift on the horizontal tail due to the change in dynamic pressure and angle of attack

$$\left(\Delta C_m\right)_H = \left(\Delta C_{m_H}\right)_e + \left(\Delta C_{m_H}\right)_q \qquad \text{(equation 4.6.1-u)}$$

$$\left.\begin{aligned} \left(\Delta C_{m_H}\right)_e &= 0.0218 \\ \left(\Delta C_{m_H}\right)_q &= 0 \end{aligned}\right\} \text{(sample problem, Section 4.6.3)}$$

$$\left(\Delta C_m\right)_H = 0.0218$$

$$\left(\Delta C_L\right)_H = -\left(\Delta C_m\right)_H \frac{\bar{c}}{\ell_H} \qquad \text{(equation 4.6.1-v)}$$

$$= -(0.0218)\left(\frac{8.17}{20.4}\right)$$

$$= -0.00873$$

Determine the total change of lift due to the propeller power effects

$$\left(\Delta C_L\right)_{\substack{\text{power} \\ \text{on}}} = \left(\Delta C_L\right)_T + \left(\Delta C_L\right)_{N_p} + \left(\Delta C_L\right)_{\Delta\alpha_W} + \left(\Delta C_L\right)_q + \left(\Delta C_L\right)_H$$

(equation 4.6.1-w)

$$= 0.0105 + 0.00529 - 0.0173 + 0.0584 - 0.00873$$

$$= 0.0482$$

The value of $\left(\Delta C_L\right)_{\substack{\text{power} \\ \text{on}}}$ from reference 4 at $\alpha = 4.0^\circ$ and $T_c' = 0.15$ is 0.080.

B. JET POWER EFFECTS ON LIFT

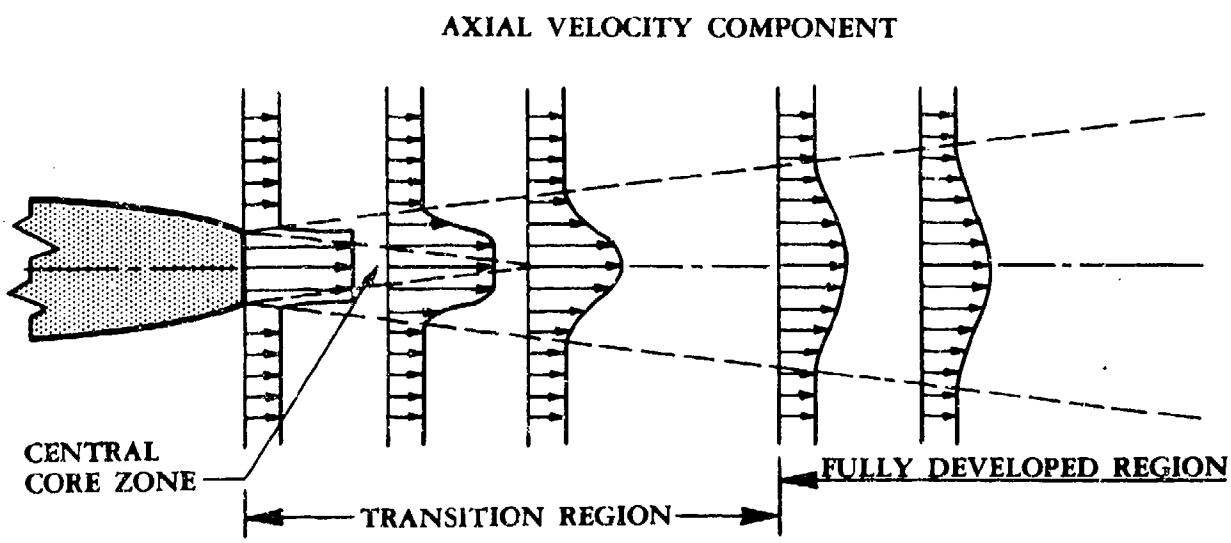
The effects of jets on the aerodynamic characteristics of vehicles are generally of smaller magnitude than the effects of propellers. There are three effects of jets on the lift of a vehicle. The first is a contribution to the lift due to the thrust component. The second is a force acting at the engine inlet duct in a direction normal to the thrust axis. This force is due to the turning of the free stream in a direction parallel to the thrust axis. The third is the induced effect of the jet on wing or tail surfaces, i.e., that caused by the jets on the surrounding flow.

The first two effects are analyzed by the methods of reference 1 at both subsonic and supersonic speeds. The third effect requires special treatment.

The following discussion on jet flow fields will help clarify some of the important distinctions between subsonic and supersonic jets operating in subsonic and supersonic flows.

Subsonic Jets in Subsonic Flow

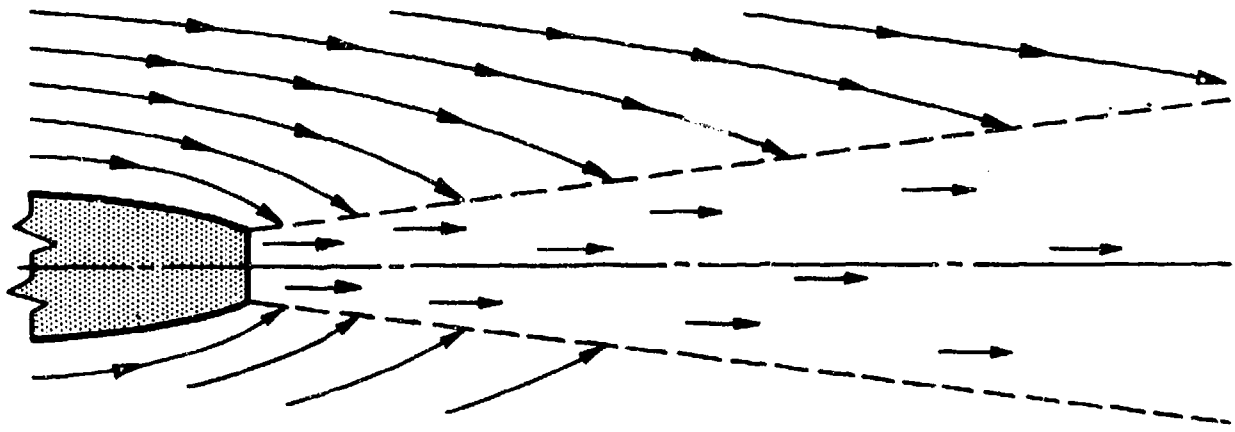
The velocity profile across a jet exit is nearly uniform. Mixing of the jet flow and the local free-stream flow starts at the lip of the jet and propagates laterally in the downstream direction. The velocity profile is modified by this viscous mixing action, and at some distance downstream of the apex of the core the velocity profiles become similar. This usually occurs at approximately eight exit-diameters from the nozzle. The region of flow less than approximately eight exit-diameters downstream is referred to as the transition region, and the region beyond this point is referred to as the fully developed region (see sketch (a)).



SKETCH (a)

Existing within the transition region is the central core zone of uniform flow, which dissipates downstream. The remaining segment of the two regions is made up of the mixing zone, which lies between the central core and the external flow.

The external flow is entrained by the jet, causing a radial inflow velocity component in the external flow as shown in sketch (b).



SKETCH (b)

Airframe components immersed in this external flow field experience changes in forces and moments due to these induced angle-of-attack changes.

Two methods are presented for calculating the interference effects of subsonic jets in a subsonic free stream. The first method is valid for downstream distances less than eight exit-diameters. This method incorporates a technique presented in reference 5 with a temperature-ratio correction from reference 6 and a span correction factor from reference 7.

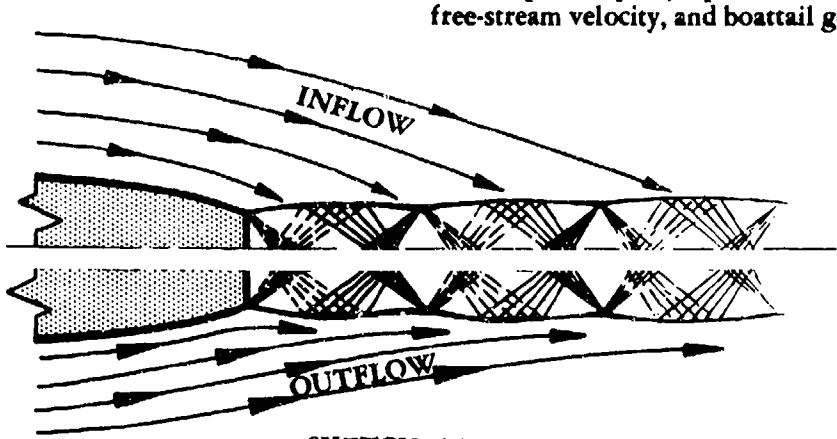
The second method is valid for downstream distances greater than eight exit-diameters. This method is based on a technique from reference 7.

Supersonic Jet in Subsonic Flow

If the jet pressure ratio becomes sufficiently large, the jet expands supersonically beyond the exit. The jet will "plume" or bulge, as shown in sketch (c).

At some station downstream, the jet reaches a condition where it is expanded to atmospheric pressure. This station is termed the equivalent jet exit station. The external flow in the region of the jet plume can cause either inflow- or outflow-radial-velocity components. In general, large jet-pressure ratios and high free-stream velocities cause outflow velocities, and lower jet-pressure ratios and low free-stream velocities cause inflow velocities resulting from the entrainment of the external flow. A quantitative evaluation of these effects is not available. The external flow downstream of the equivalent jet exit station always has an inflow velocity component and is similar in this respect to subsonic jets.

Flow depends upon jet pressure ratio, free-stream velocity, and boattail geometry

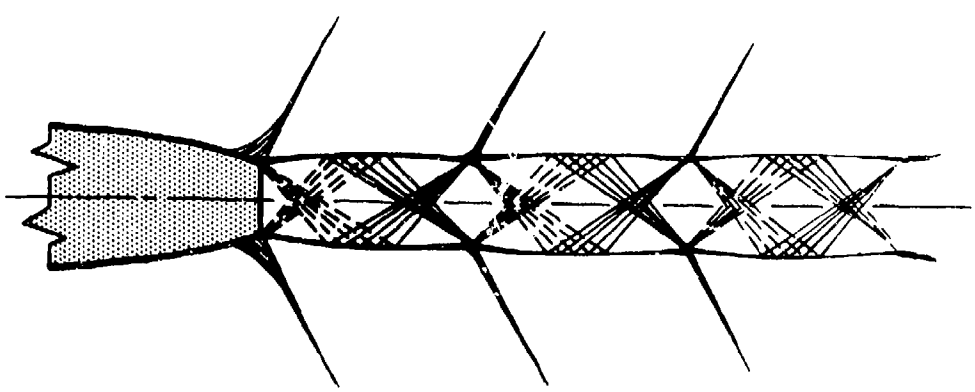


SKETCH (c)

No accurate flow model is available for predicting the jet interference effects of a supersonic jet exhausting into a subsonic flow. However, an approximate method is presented that is based on the method for analyzing subsonic jets in subsonic flow. The accuracy of this method has not been established.

Supersonic Jets in Supersonic Flow

At supersonic speeds the exhaust from supersonic jets causes strong disturbances in the external flow field in the form of shock and expansion waves. A typical flow pattern is shown in sketch (d).



SKETCH (d)

Jets become greatly underexpanded at extreme altitudes, a phenomenon that results in strong effects on the flow upstream of the jet exit. Some limited data on this problem are available in reference 8.

The correct approach for analyzing the lift increment should consider the change in pressure distribution on the wing or tail due to the presence of the jet. The surface pressure distribution is a function of the free-stream Mach number and jet pressure ratio. Unfortunately, insufficient test data are available to provide complete charts for this estimation procedure. Test data at $M_\infty = 2.0$ and a jet pressure ratio of 7.0 from reference 9 are presented in figure 4.6.1-33 as representative data. The chart shows pressure contours at the vertical plane of symmetry of the jet. It is intended that these limited data, together with a description of the procedure, will provide some feeling for the problem.

DATCOM METHOD

The Datcom method estimates the power-on lift curves, based on power-off lift curves, as a function of angle of attack, thrust coefficient, engine-inlet area, and horizontal-tail parameters.

This method analyzes the increments of lift coefficient due to jet power effects in the following order:

1. Lift component of thrust
2. Lift component due to the turning of the free-stream flow parallel to the thrust axis
3. Lift component due to jet interference effects

After the above lift increments for a given angle of attack have been calculated, the accumulated total is then applied to the power-off lift curve to obtain a point on the power-on lift curve. After several points have been generated (by considering several angles of attack), the linear section of the power-on lift curve is obtained for a given thrust coefficient.

The above increments in lift can be determined by the following steps. (Reference should be made to figure 4.6-13b for geometric definitions. In all cases the lift increments are based on the wing reference area.)

Step 1. Calculate the lift component of thrust as follows:

a. Calculate the angle of attack of the thrust axis to the free stream α_T by

$$\alpha_T = i_T + \alpha \qquad 4.6.1\text{-a}$$

b. Calculate the thrust coefficient per engine T_c' (if not given or assumed) by

$$T_c' = \frac{T}{q_\infty S_W} \qquad 4.6.1\text{-b}$$

where the thrust per engine T is a given or chosen quantity.

c. Calculate the lift component of thrust by

$$\left(\Delta C_L\right)_T = n\, T_c' \sin \alpha_T \qquad 4.6.1\text{-c}$$

where n is the number of engines. This equation is valid only when the thrust coefficients and the angles of attack of the thrust axis to the free stream are equal for all n engines.

Step 2. Calculate the lift component per engine due to the turning of the free-stream flow in a direction parallel to the thrust axis as follows:

a. Calculate the angle between the thrust axis and the local velocity α_j at the engine inlet by

$$\alpha_j = \alpha_T + \epsilon_u \qquad 4.6.1\text{-x}$$

where the upwash ahead of the wing ϵ_u is obtained by

$$\epsilon_u = \frac{\partial \epsilon_u}{\partial \alpha} (\alpha_W - \alpha_0) \qquad 4.6.1\text{-m}$$

and the downwash gradient $\frac{\partial \epsilon_u}{\partial \alpha}$ is obtained from Section 4.4.1.

b. Calculate the turning component of lift by

$$\left(\Delta C_L\right)_{N_j} = \frac{2A_1 \sin \alpha_j}{S_W} \qquad 4.6.1\text{-y}$$

For multiple-engine configurations, the total lift component due to the turning of the free-stream flow is found by summing the individual lift increments due to each engine.

Step 3. Calculate the lift component per engine due to the jet interference effects.

The various possible combinations of Mach number for the free-stream and nozzle exit conditions require different combinations to be analyzed separately. Methods for calculating four different jet interaction cases are presented. The surface affected is assumed to be a horizontal tail. Application to other lifting surfaces and to other bodies is similar.

Case 1. Subsonic Free Stream – Subsonic Jet – Downstream Distance Less than Eight Exit-Diameters

a. Obtain the lift-curve slope of the horizontal tail $C_{L_{\alpha_H}}$ from Section 4.1.3.2.

b. Obtain the ratio of the horizontal-tail to free-stream dynamic pressure q_H/q_∞ at the quarter-chord of the horizontal-tail MAC from wind-tunnel-test data or Section 4.4.1.

c. From figure 4.6.1-28 obtain a value for the mean-effective-downwash ratio $\Delta\bar{\epsilon}/\Delta\epsilon$ as a function of aircraft geometry.

d. From figure 4.6.1-29 obtain the equivalent-jet-velocity ratio V_j'/V_∞ as a function of the actual-jet-velocity ratio V_j/V_∞ and the ratio of ambient temperature to jet static temperature.

e. From figures 4.6.1-30a through -30c obtain a value for the downwash increment $\Delta\epsilon$ as a function of aircraft geometry and equivalent-jet-velocity ratio.

f. Calculate the mean-effective-downwash increment $\Delta\bar{\epsilon}$ by

$$\Delta\bar{\epsilon} = \left(\frac{\Delta\bar{\epsilon}}{\Delta\epsilon}\right) \Delta\epsilon \qquad 4.6.1\text{-z}$$

g. Calculate the increment in lift per engine due to jet interference effects by

$$\left(\Delta C_L\right)_\epsilon = -C_{L_{\alpha_H}} \frac{S_H}{S_W} \frac{q_H}{q_\infty} \Delta\bar{\epsilon} \qquad 4.6.1\text{-aa}$$

For multiple-engine configurations, the total lift component due to jet interference effects is found by summing the individual lift increments due to each engine.

Case II. Subsonic Free Stream – Subsonic Jet – Downstream Distances Greater than Eight Exit-Diameters

a. Obtain the lift-curve slope of the horizontal tail $C_{L_{\alpha_H}}$ from Section 4.1.3.2.

b. Obtain the ratio of the horizontal-tail to free-stream dynamic pressure q_H/q_∞ at the quarter-chord of the horizontal-tail MAC from wind-tunnel-test data or Section 4.4.1.

c. From figure 4.6.1-28 obtain a value for the mean-effective-downwash ratio $\Delta\bar{\epsilon}/\Delta\epsilon$ as a function of aircraft geometry.

d. From figure 4.6.1-31 obtain a value for $z_j'\Delta\epsilon/x_H$ as a function of aircraft geometry and thrust coefficient.

e. Calculate the jet-induced downwash angle $\Delta\epsilon$ by

$$\Delta\epsilon = \frac{z_j'\Delta\epsilon}{x_H'}\frac{x_H'}{z_j'} \qquad \text{4.6.1-bb}$$

$$\text{where } x_H' = x_j' + x_e' \qquad \text{4.6.1-cc}$$

and x_j' is usually expressed as

$$x_j' = 4.6\ R_j \qquad \text{4.6.1-dd}$$

f. Calculate the mean-effective-downwash increment $\Delta\bar{\epsilon}$ by

$$\Delta\bar{\epsilon} = \left(\frac{\Delta\bar{\epsilon}}{\Delta\epsilon}\right)\Delta\epsilon \qquad \text{4.6.1-z}$$

g. Calculate the increment in lift per engine due to jet interference effects by

$$\left(\Delta C_L\right)_\epsilon = -C_{L_{\alpha_H}}\frac{S_H}{S_W}\frac{q_H}{q_\infty}\Delta\bar{\epsilon} \qquad \text{4.6.1-aa}$$

For multiple-engine configurations, the total lift component due to jet interference effects is found by summing the individual lift increments due to each engine.

Case III. Subsonic Free Stream – Supersonic Jet – Distances Downstream of the Fully Expanded Flow

a. From figure 4.6.1-32a obtain a value for the equivalent-jet orifice radius ratio R_j'/R_j as a function of the jet-exit total-pressure ratio.

b. From figure 4.6.1-32b obtain a value for the downstream displacement of the equivalent-jet orifice as a function of the equivalent-jet orifice radius.

The downstream displacement distance corresponds to the point at which the supersonic-jet flow has expanded to ambient pressure. The corresponding jet ratio at this station is the equivalent radius R_j'. These values are used in lieu of the actual jet radius and jet location in approximating the inflow velocities of the surrounding flow downstream of this equivalent jet-exit station.

Depending on the location of the surface of interest, the remaining steps are identical to those of case I (less than eight exit-diameters downstream) or case II (greater than eight exit-diameters downstream). For locations upstream of the fully expanded flow no method is available.

As pointed out in the discussion, the accuracy of this method is not known.

Case IV. Supersonic Free Stream – Supersonic Jet

A complete method is not presented because of a lack of wind-tunnel test data required for the formulation of design charts. However, if wind-tunnel data are available the following procedure is suggested:

a. Divide the surface under consideration into incremental areas ΔS_H.

b. Calculate the respective axial and radial locations of the incremental areas relative to the jet exit.

c. Construct a pressure-coefficient-contour chart from available data (see figure 4.6.1-33).

d. Obtain values of $\Delta p/q_\infty$ for each incremental area from the pressure-coefficient-contour chart as a function of their relative locations.

e. Sum the incremental forces acting over the surfaces to obtain the total change in lift coefficient by

$$\Delta C_L = \frac{1}{S_W} \Sigma \left[\Delta S_H \frac{\Delta p}{q_\infty} \right] \qquad 4.6.1\text{-ee}$$

By using the above procedure, several increments in horizontal-tail lift coefficient were calculated for the configuration tested in reference 10. The calculations were computed from the data of figure 4.6.1-33 for a variety of tail positions at Mach number of 1.9 and a jet pressure ratio of 6.66. The results of the calculations revealed errors ranging from 15 to 133 percent.

The total change in aircraft lift due to jet power effects is obtained by summing all lift components, i.e.,

$$\left(\Delta C_L\right)_{\substack{\text{power} \\ \text{on}}} = \left(\Delta C_L\right)_T + \left(\Delta C_L\right)_{N_j} + \left(\Delta C_L\right)_e \qquad 4.6.1\text{-ff}$$

Sample Problem

The following example is based on the four-engine DC-8 configuration. The example is presented for one value of α and one value of T_c'. The lift due to jet-interference effects is calculated by using the methods of case II, since the downstream distance of the horizontal tail is greater than eight engine exit-diameters.

Given:

Wing Parameters:

$S_W = 2930\ ft^2$ $\quad \bar{c} = 272.8$ in. $\quad A = 7.52$

$i_W = 0$ $\quad \alpha = 5°$ $\quad \alpha_0 = -2.5°$ (flaps up)

Horizontal-Tail Parameters:

$S_H = 560\ ft^2$ $\quad \bar{c}_H$ 153.2 in. $\quad C_{L_{\alpha_H}} = 0.0627$/deg (Section 4.1.3.2)

$q_H/q_\infty = 0.968$ (Section 4.4.1) $\quad \ell_H = 855.0$ in. $\quad b_H = 570.0$ in.

Engine Parameters:

Outboard Engines (2) $\quad z_T = 53.0$ in. $\quad z_j' = 175.7$ in.

$x_I = 145.2$ in. $\quad x_e' = 788.0$ in. $\quad y_T = 44.6$ ft

$\partial\epsilon_u/\partial\alpha = 0.17$ (Section 4.4.1) $\quad R_j = 20$ in. $\quad A_I = 13.64\ ft^2$

$i_T = 3.6°$ $\quad T = 12{,}500$ lb

Inboard Engines (2) $\quad z_T = 70.8$ in. $\quad z_j' = 201.7$ in.

$x_I = 283.8$ in. $\quad x_e' = 927.0$ in. $\quad y_T = 25.7$ ft

$\partial\epsilon_u/\partial\alpha = 0.24$ (Section 4.4.1) $\quad R_j = 20$ in. $\quad A_I = 13.64\ ft^2$

$i_T = 3.6°$ $\quad T = 12{,}500$ lb

Additional Parameters:

$M = 0.2$ $\quad q_\infty = 57.2$ psf $\quad h = 1000$ ft

Compute:

Determine the lift component of thrust

$$\alpha_T = i_T + \alpha \qquad \text{(equation 4.6.1-a)}$$

$$= 3.6 + 5 = 8.6°$$

$$T_c' = \frac{T}{q_\infty S_W} \qquad \text{(equation 4.6.1-b)}$$

$$= \frac{12{,}500}{(57.2)\,(2930)} = 0.0746 \text{ (per engine)}$$

$$\left(\Delta C_L\right)_T = n\, T_c' \sin \alpha_T \qquad \text{(equation 4.6.1-c)}$$

$$= (4)\,(0.0746)\,(0.1495)$$

$$= 0.0446$$

Determine the lift component due to the turning of the free stream

$$\alpha_W = \alpha + i_W \qquad \text{(equation 4.6.1-h)}$$

$$= 5 + 0 = 5°$$

$$\epsilon_u = \frac{\partial \epsilon_u}{\partial \alpha} (\alpha_W - \alpha_0) \qquad \text{(equation 4.6.1-m)}$$

$$\left(\epsilon_u\right)_{\substack{\text{outboard}\\ \text{engine}}} = (0.17)\,(5 + 2.5) = 1.27°$$

$$\left(\epsilon_u\right)_{\substack{\text{inboard}\\ \text{engine}}} = (0.24)\,(5 + 2.5) = 1.80°$$

$$\alpha_j = \alpha_T + \epsilon_u \qquad \text{(equation 4.6.1-x)}$$

$$\left(\alpha_j\right)_{\substack{\text{outboard}\\ \text{engine}}} = 8.6 + 1.27 = 9.87°$$

$$\left(\alpha_j\right)_{\substack{\text{inboard}\\ \text{engine}}} = 8.6 + 1.80 = 10.4°$$

$$\left(\Delta C_L\right)_{N_j} = \frac{2A_1 \sin \alpha_j}{S_W} \qquad \text{(equation 4.6.1-y)}$$

Considering the lift increment due to both outboard engines

$$\left[\left(\Delta C_L\right)_{N_j}\right]_{\substack{\text{outboard}\\\text{engines}}} = \frac{(2)\,(13.64)\,(0.1714)\,(2)}{2930} = 0.00319$$

Considering the lift increment due to both inboard engines

$$\left[\left(\Delta C_L\right)_{N_j}\right]_{\substack{\text{inboard}\\\text{engines}}} = \frac{(2)\,(13.64)\,(0.1805)\,(2)}{2930} = 0.00336$$

The total lift component due to the turning of the free stream is

$$\left(\Delta C_L\right)_{N_j} = \left[\left(\Delta C_L\right)_{N_j}\right]_{\substack{\text{outboard}\\\text{engines}}} + \left[\left(\Delta C_L\right)_{N_j}\right]_{\substack{\text{inboard}\\\text{engines}}}$$

$$= 0.00319 + 0.00336$$

$$= 0.00655$$

Determine the lift component due to jet interference effects on the horizontal tail. The method of case II will be used to evaluate the jet interference effects, since $(\ell_H/R_j) > 8$.

$$\left.\frac{\Delta\bar{\epsilon}}{\Delta\epsilon}\right|_{\substack{\text{inboard}\\\text{engines}}} = 0.37 \qquad \text{(figure 4.6.1-28)}$$

$$\left.\frac{\Delta\bar{\epsilon}}{\Delta\epsilon}\right|_{\substack{\text{outboard}\\\text{engines}}} = 0.10 \qquad \text{(figure 4.6.1-28)}$$

$$\left.\frac{z_j'\Delta\epsilon}{x_H'}\right|_{\substack{\text{inboard}\\\text{engines}}} = 0.07 \qquad \text{(figure 4.6.1-31)}$$

$$\left.\frac{z_j'\Delta\epsilon}{x_H'}\right|_{\substack{\text{outboard}\\\text{engine}}} = 0.08 \qquad \text{(figure 4.6.1-31)}$$

$$x'_H = x'_j + x'_e \qquad \text{(equation 4.6.1-cc)}$$

$$x'_j = 4.6\ R_j \qquad \text{(equation 4.6.1-dd)}$$

$$\left(x'_H\right)_{\substack{\text{inboard}\\ \text{engine}}} = (4.6)\ (20) + 927$$

$$= 1019 \text{ in.}$$

$$\left(x'_H\right)_{\substack{\text{outboard}\\ \text{engine}}} = (4.6)\ (20) + 788$$

$$= 880 \text{ in.}$$

$$\Delta\epsilon = \frac{z'_j \Delta\epsilon}{x'_H} \frac{x'_H}{z'_j} \qquad \text{(equation 4.6.1-bb)}$$

$$\left(\Delta\epsilon\right)_{\substack{\text{inboard}\\ \text{engine}}} = (0.07)\ \frac{(1019)}{(201.7)}$$

$$= 0.354$$

$$\left(\Delta\epsilon\right)_{\substack{\text{outboard}\\ \text{engine}}} = (0.08)\ \frac{(880)}{175.7}$$

$$= 0.40$$

$$\Delta\bar{\epsilon} = \left(\frac{\Delta\bar{\epsilon}}{\Delta\epsilon}\right)_i \Delta\epsilon \qquad \text{(equation 4.6.1-z)}$$

$$\left(\Delta\bar{\epsilon}\right)_{\substack{\text{inboard}\\ \text{engines}}} = (0.37)\ (0.354)$$

$$= 0.131$$

$$\left(\Delta\bar{\epsilon}\right)_{\substack{\text{outboard}\\ \text{engines}}} = (0.10)\ (0.40)$$

$$= 0.04$$

$$\left(\Delta C_L\right)_\epsilon = -C_{L_{\alpha_H}} \frac{S_H}{S_W} \frac{q_H}{q_\infty} \Delta\bar{\epsilon} \qquad \text{(equation 4.6.1-aa)}$$

$$\left[\left(\Delta C_L\right)_\epsilon\right]_{\substack{\text{inboard}\\\text{engines}}} = -(0.0627)\ \frac{560}{2930}\ (0.968)\ (0.131)$$

$$= -0.00152$$

$$\left[\left(\Delta C_L\right)_\epsilon\right]_{\substack{\text{outboard}\\\text{engines}}} = -(0.0627)\ \frac{560}{2930}\ (0.968)\ (0.04)$$

$$= 0.00046$$

The total lift component due to jet interference effects on the horizontal tail is

$$\left(\Delta C_L\right)_\epsilon = -0.00152 - 0.00046$$

$$= -0.0020$$

$$\left(\Delta C_L\right)_{\substack{\text{power}\\\text{on}}} = \left(\Delta C_L\right)_T + \left(\Delta C_L\right)_{N_j} + \left(\Delta C_L\right)_\epsilon \qquad \text{(equation 4.6.1-ff)}$$

$$= (0.0446) + (0.00655) + (-0.0020)$$

$$= 0.049$$

4.6.2 POWER EFFECTS ON MAXIMUM LIFT

A. PROPELLER POWER EFFECTS ON MAXIMUM LIFT

Over the linear lift-curve-slope range, increases in lift due to propeller power result from the factors discussed in Section 4.6.1, paragraph A. However, near or at maximum lift an additional increase in lift coefficient occurs because the angle of attack for stall increases with power. This effect depends primarily upon the ratio of the immersed wing area to the total wing area. An empirical method, based on data from references 1 and 2, is presented in this section for estimating the maximum lift increase due to power.

DATCOM METHOD

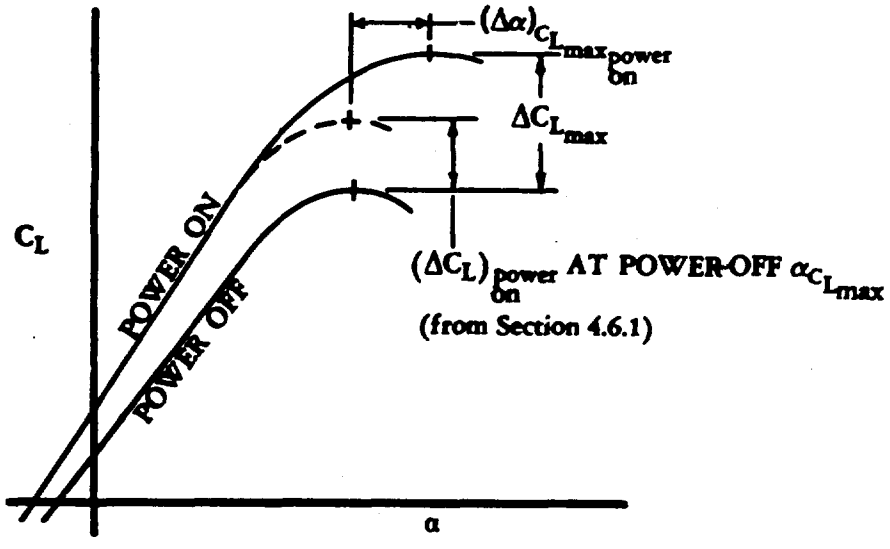
Step 1. From figure 4.6.2-3 obtain a value for the empirical constant K as a function of the ratio of immersed wing area to total wing area S_i/S_W. (The immersed wing area S_i is calculated in Section 4.6.1.)

Step 2. Calculate the increment in lift due to power $(\Delta C_L)_{\substack{power\\on}}$ at the angle of attack for maximum lift, power off. This value is obtained from equation 4.6.1-w of Section 4.6.1.

Step 3. Calculate the increment of maximum lift due to propeller power by

$$\Delta C_{L_{max}} = K\left(\Delta C_L\right)_{\substack{power\\on}} \qquad 4.6.2\text{-a}$$

The shift in $\alpha_{C_{L_{max}}}$ for the power-on lift curve can only be approximated, based on the shape of the power-off curve. Based on this geometrical approximation, the complete lift curve can then be constructed as shown in sketch (a).



SKETCH (a)

Table 4.6.2-A compares the results obtained by this method with test data.

Sample Problem

Given:

$S_W = 314\ ft^2$ $\quad T_c' = 0.20$ $\quad \left(\alpha_{stall}\right)_{\substack{power \\ off}} = 16°$ (wind-tunnel data)

$\left(\Delta C_L\right)_{\substack{power \\ on}} = 0.438$ (Section 4.6.1) $\quad S_i = 114\ ft^2$ (Section 4.6.1)

Compute:

$$\frac{S_i}{S_W} = \frac{114}{314} = 0.364$$

$K = 1.38$ (figure 4.6.2-3)

$$\Delta C_{L_{max}} = K\left(\Delta C_L\right)_{\substack{power \\ on}} \quad \text{(equation 4.6.2-a)}$$

$$= (1.38)(0.438)$$

$$= 0.604$$

B. JET POWER EFFECTS ON MAXIMUM LIFT

The maximum lift due to jet power is described in Section 4.6.1, paragraph B, since the angle of attack for stall does not exhibit an increase with power as in the case for propellers. The increment in maximum lift is therefore found by calculating the lift increment at the angle of attack for maximum lift, power off, by using the method of Section 4.6.1. The shape of the power-on lift curve near stall is similar to that of the power-off curve determined by using other sections of the Datcom.

4.6.3 POWER EFFECTS ON PITCHING-MOMENT VARIATION WITH ANGLE OF ATTACK

A. PROPELLER POWER EFFECTS ON PITCHING MOMENT

This section presents a method from references 1 and 2 for estimating the power effects of propellers on the pitching-moment characteristics of a vehicle. Since power effects on pitching-moment characteristics are primarily a result of the increments in lift due to propellers, part A of Section 4.6.1 is directly applicable to this section, and the reader is referred to that discussion for a general description of the fundamental phenomena.

DATCOM METHOD

The Datcom method estimates the power-on pitching-moment curves based on power-off curves, as a function of angle of attack, thrust coefficient, and lift coefficient.

This method analyzes the increments of pitching-moment coefficient due to propeller-power effects in the following order:

1. Offset of the thrust axis from the origin of the axes
2. Propeller normal force due to angle of attack
3. Change in dynamic pressure over the section of the wing in the propeller slipstream
4. Change in lift of the wing caused by power effects
5. Change in dynamic pressure acting on the horizontal tail
6. Change in angle of attack at the horizontal tail

After the above pitching-moment increments for a given angle of attack have been calculated, the accumulated total is then applied to the power-off pitching-moment curve to obtain a point on the power-on pitching-moment curve. After several points have been generated (by considering several angles of attack), the linear section of the power-on pitching-moment curve is obtained for a given thrust coefficient.

All increments of pitching-moment coefficients are nondimensionalized with respect to the product of wing area and wing MAC. Their moment center is at the quarter-chord point of the wing MAC.

Step 1. Calculate the increment in pitching-moment coefficient per engine due to an offset of the thrust axis from the origin of the axes by

$$\left(\Delta C_m\right)_T = T_c' \frac{z_T}{\bar{c}} \qquad 4.6.3\text{-a}$$

where the thrust coefficient is a given or chosen quantity. For multiple-engine configurations the total pitching-moment component is found by summing the component due to each engine.

Step 2. Calculate the increment in pitching-moment coefficient due to the propeller normal force by

$$\left(\Delta C_m\right)_{N_p} = \left(\Delta C_L\right)_{N_p} \frac{x_p}{\bar{c}} \frac{\cos i_T}{\cos \alpha_T} \qquad 4.6.3\text{-b}$$

where $(\Delta C_L)_{N_p}$ is obtained from Section 4.6.1 and α_T is given by equation 4.6.1-a, i.e.,

$$\alpha_T = \alpha + i_T$$

Step 3. Calculate the increment in pitching-moment coefficient due to the change in slipstream dynamic pressure acting on the wing as follows:

a. Calculate the zero-lift pitching-moment coefficient $(C_{m_0})_i$ of those components of the tail-off configuration that are immersed in the slipstream by

$$\left(C_{m_0}\right)_i = \left(C_{m_0}\right)_{\text{wing-body}} - \left(C_{m_0}\right)_{\substack{\text{area not} \\ \text{immersed}}} \qquad 4.6.3\text{-c}$$

where $(C_{m_0})_{\text{wing-body}}$ must be obtained from wind-tunnel tests and $(C_{m_0})_{\substack{\text{area not} \\ \text{immersed}}}$ may be obtained from Section 4.1.4.1 and is based on the combined planform area of the wing not immersed in the propeller slipstream.

b. Calculate the change in slipstream dynamic pressure given by equation 4.6.1-r, i.e.,

$$\frac{\Delta q_s}{q_\infty} = \frac{S_W T_c'}{\pi R_p^2}$$

c. Calculate the pitching-moment increment due to the change in slipstream dynamic pressure by

$$\left(\Delta C_m\right)_q = \frac{\Delta q_s}{q_\infty} \left(C_{m_0}\right)_i \qquad 4.6.3\text{-d}$$

Step 4. Calculate the increment in pitching-moment coefficient due to the change in lift of the wing caused by power effects as follows:

a. Calculate the lift increments $(\Delta C_L)_q$ and $(\Delta C_L)_{\Delta\alpha_W}$ by the method in Section 4.6.1.

b. Calculate the pitching-moment increment due to the immersed wing lift increments by

$$\left(\Delta C_m\right)_L = \left[\left(\Delta C_L\right)_q + \left(\Delta C_L\right)_{\Delta\alpha_W}\right] \frac{x_W}{\bar{c}} \qquad 4.6.3\text{-e}$$

where x_W is the longitudinal distance from the aerodynamic center of that portion of the wing immersed in the propeller slipstream to the moment-reference-center location, positive for the aerodynamic center forward of the moment reference center (see Figure 4.6-12).

Step 5. Calculate the increment in pitching-moment coefficient due to the change in dynamic pressure acting on the horizontal tail as follows:

a. Calculate the angle of attack at the horizontal tail α_H by

$$\alpha_H = \alpha + i_H - \left(\epsilon_H\right)_{\substack{\text{power}\\\text{off}}} \qquad 4.6.3\text{-f}$$

where $(\epsilon_H)_{\substack{\text{power}\\\text{off}}}$ is obtained in Section 4.4.1.

b. Obtain a value for the lift-curve slope of the horizontal tail $(C_{L_{\alpha_H}})_{\substack{\text{power}\\\text{off}}}$ from Section 4.1.3.2.

c. Calculate the lift coefficient of the horizontal tail by

$$C_{L_H} = \left(C_{L_{\alpha_H}}\right)_{\substack{\text{power}\\\text{off}}} \alpha_H \qquad 4.6.3\text{-g}$$

d. From figure 4.6.3-14 or 4.6.3-15 obtain a value for the change in downwash at the horizontal tail $\Delta\epsilon_H$ as a function of geometric characteristics, thrust coefficient, and the power-off downwash angle.

e. Calculate the power-on downwash angle at the horizontal tail by

$$\left(\epsilon_H\right)_{\substack{\text{power}\\\text{on}}} = \left(\epsilon_H\right)_{\substack{\text{power}\\\text{off}}} + \Delta\epsilon_H \qquad 4.6.3\text{-h}$$

f. Calculate the geometric distance z_s by equation 4.6.1-n, i.e.

$$z_s = x_p \tan\left(\alpha_T + \epsilon_u - \epsilon_p\right) - z_T$$

g. Calculate the geometric distance $z_{H_{eff}}$ by

$$z_{H_{eff}} = z_s + z_H + \ell_H \tan\left[\alpha_T + \epsilon_u - \epsilon_p - \left(\epsilon_H\right)_{\substack{\text{power}\\\text{on}}}\right] \qquad 4.6.3\text{-i}$$

h. From figure 4.6.3-16 obtain a value for the change in dynamic pressure $\Delta q_H/q_\infty$ as a function of geometric characteristics and thrust coefficient.

i. Calculate the change in pitching-moment coefficient due to the incremental change in dynamic pressure at the horizontal tail by

$$\left(\Delta C_{m_H}\right)_q = -C_{L_H} \frac{\Delta q_H}{q_\infty} \frac{S_H}{S_W} \frac{\ell_H}{\bar{c}} \qquad 4.6.3\text{-j}$$

Step 6. Calculate the increment in pitching-moment coefficient due to the change in angle of attack of the horizontal tail as follows:

a. Calculate the power-on dynamic-pressure ratio at the horizontal tail by

$$\left(\frac{q_H}{q_\infty}\right)_{\substack{\text{power}\\\text{on}}} = \left(\frac{q_H}{q_\infty}\right)_{\substack{\text{power}\\\text{off}}} + \frac{\Delta q_H}{q_\infty} \qquad 4.6.3\text{-k}$$

where $\Delta q_H/q_\infty$ is found in step 5.h and $(q_H/q_\infty)_{\substack{\text{power}\\\text{off}}}$ is obtained in Section 4.4.1.

b. Calculate the change in pitching-moment coefficient due to the change in angle of attack at the horizontal tail by

$$\left(\Delta C_{m_H}\right)_\epsilon = C_{L_{\alpha_H}} \Delta\epsilon_H \frac{S_H}{S_W} \frac{\ell_H}{\bar{c}} \left(\frac{q_H}{q_\infty}\right)_{\substack{\text{power}\\\text{on}}} \qquad 4.6.3\text{-}\ell$$

where $\Delta\epsilon_H$ is found in Step 5.d.

Step 7. Calculate the total incremental change in pitching-moment coefficient due to propeller power effects by

$$\left(\Delta C_m\right)_{\substack{\text{power}\\\text{on}}} = \left(\Delta C_m\right)_T + \left(\Delta C_m\right)_{N_p} + \left(\Delta C_m\right)_q + \left(\Delta C_m\right)_L + \left(\Delta C_{m_H}\right)_q + \left(\Delta C_{m_H}\right)_\epsilon \qquad 4.6.3\text{-m}$$

Sample Problem

The configuration used in this sample problem is the same as that used in the sample problem for propeller effects on lift in Section 4.6.1.

Given:

Wing Parameters:

$S_W = 380\ ft^2 \qquad S_i = 117.4\ ft^2 \qquad b_i = 12.8\ ft$ } (calculated in Section 4.6.1)

$\left(\Delta C_L\right)_{N_p} = 0.00529$

$\left(\Delta C_L\right)_{\Delta\alpha_W} = -0.0173$ } (calculated in Section 4.6.1)

$\left(\Delta C_L\right)_q = 0.0584$

$\bar{c} = 8.17\ ft \qquad \Lambda_{c/4} = 0 \qquad c_i = 9.17\ ft \qquad \bar{c}_{\substack{\text{area not}\\ \text{immersed}}} = 7.50\ ft$

$A_{\substack{\text{area not}\\ \text{immersed}}} = 4.90 \qquad \left(c_{m_0}\right)_{\substack{\text{area not}\\ \text{immersed}}} = -0.07$ (average value for wing sections not immersed in the slipstream)

$\left(C_{m_0}\right)_{\text{wing-body}} = -0.080$ (tail-off wind-tunnel data) $\qquad x_W = 0$

$\alpha = 4.0° \qquad \alpha_T = 4.0° \qquad \epsilon_u = 1.14° \qquad \epsilon_p = 0.59°$

$\epsilon_{\substack{\text{power}\\ \text{off}}} = 4.0°$ (wind-tunnel data or Section 4.4.1)

Horizontal-Tail Parameters:

$S_H = 80\ ft^2 \qquad \frac{S_{H_i}}{S_H} = \frac{59}{80} = 0.738 \qquad i_H = 0 \qquad A_H = 4.26$

$\lambda_H = 0.59 \qquad \Lambda_{H_{c/4}} = 0 \qquad \left(\frac{q_H}{q_\infty}\right)_{\substack{\text{power}\\ \text{off}}} = 0.9$ (Section 4.4.1)

$C_{L_{\alpha_H}} = 0.057 \quad z_H = -4.10 \text{ ft} \quad z_{H_T} = 3.0 \text{ ft} \quad \ell_H = 20.4 \text{ ft}$

Engine Parameters:

$T_c' = 0.15 \quad R_p = 6.79 \text{ ft} \quad x_p = 10.9 \text{ ft} \quad z_T = -1.10 \text{ ft}$

Compute:

Determine the increment of pitching moment due to an offset of the thrust axis from the origin of the axes

$$\left(\Delta C_m\right)_T = T_c' \frac{z_T}{\bar{c}} \qquad \text{(equation 4.6.3-a)}$$

$$= (0.15) \frac{(-1.10)}{(8.17)} = -0.0202$$

Determine the increment of pitching moment due to the propeller normal force

$$\left(\Delta C_m\right)_{N_p} = \left(\Delta C_L\right)_{N_p} \frac{x_p}{\bar{c}} \frac{1}{\cos \alpha_T} \qquad \text{(equation 4.6.3-b)}$$

$$= (0.00529) \frac{10.9}{8.17} \frac{1}{\cos 4.0^\circ} = 0.00707$$

Determine the increment of pitching moment due to the change in dynamic pressure
